It is undesirable that the Mexican stock be in the names of any person or persons. The stock of the Mexican corporation should be nominative stock held by, and in the name of, the holding company with the exception of one share each of the stock issued to the directors and commissary to qualify them. These qualifying shares must necessarily be to bearer, and under the law must be deposited in the treasury of the Mexican company. By following these simple rules much risk and danger of loss is avoided.

THE REPORT of the United States Steel Corporation for the last quarter of 1908 shows no material changes from the earlier part of the year. Further comment on the year's results is reserved.

Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Sampling by Machine

Several years of experience with sellers and buyers of ore while in the public sampling business, and in several mining districts, and recently the reading of discussions in the technical journals have convinced me that much of the misunderstanding and criticism of existing sampling methods has been due to the failure on the part of many to realize two important facts: (1) That ore sampling on a large scale is not simply a theoretical problem which can be solved once for all, and for every locality, by mathematics alone; and (2) that it is a commercial enterprise calling for continual compromises between the theory of the subject and local requirements and conditions, and the allowable cost of plant and of operation.

The first object of all honest sampling methods is ultimately to take from a lot of ore a small amount which will contain in the same proportion all the elements of the original lot. This small amount must be so finely divided, i.e., crushed, that the assayer and chemist can weigh up from it, for assay and analysis, successive charges that will within reasonable limits maintain these same proportions. The second object is to accomplish this result at a reasonable rate of speed, and what is of equal importance, at a not excessive cost per ton of ore handled.

MIXING

The attainment of these objects may not seem difficult; but the many failures and disappointments prove that to obtain this result is anything but simple, although I think the great reason for the failures of many of the past and present methods is a total misunderstanding of the basic conditions and requirements of both hand and mechanical sampling. In most treatises and discussions of ore-sampling methods a great deal of weight is placed on the importance of *mixing* the ore before and during the sampling process. To my mind this *mixing* is impossible of attainment in large lots of ore as shipped from the mine, although its probability may increase with the finer condition or crushing of the ore. This ore frequently consists of particles varying from one foot to one one-hundredth inch in the greatest dimension, and may be almost dry or contain 20 per cent. or more moisture. Whenever such ore is dumped

from a car, thrown into a cone, or piled up from a shovel from a barrow or from a spout, there is an immediate partial separation of the coarser from the finer particles, varying somewhat with the moisture of the ore, and constantly increasing with the size of the cone or pile. I have never seen any device which satisfactorily prevented such separation; ore passing through an inclined spout or through a revolving barrel will show it plainly; and even a nearly flat shaking tray will show the coarser particles riding the fines and traveling at a slightly greater speed.

If it were feasible to crush all the ore in a lot to 10, 50, 100, or even finer mesh, the probability of being able to mix these particles would increase with the fineness of the crushing, but the cost of this work, and the fact that the smelters desire the bulk of the ore to be as coarse as possible, prohibits such a method. Therefore, as I stated at the beginning, ore sampling, as with many enterprises, is a compromise between the theory of the subject and the commercial requirements.

FRACTIONAL MIXING

This compromise has resulted in what we might call a process of fractional mixing; i.e., instead of trying to prepare the ore so that we can ultimately mix the whole lot, we first crush as coarse as permissible, and then take a certain portion, as one-half from the carefully arranged pile in the coning or other hand methods, or take small amounts at regular intervals from the falling stream in mechanical methods. The small portion taken out of the stream by every revolution of the sampling machine is passed along for further crushing, after which it is again reduced in volume by a similar process and so passed along continually through from two to five machines until it reaches a temporary resting place in the sample bin.

Either no attempt, or at least but a crude attempt is made at mixing the several cuts taken by any one machine. The ore is frequently retarded in its course by the use of revolving barrels or shaking trays, but their influence on the correctness of the sample is a matter of unsettled discussion. Personally I think they have little or no influence in this direction. From the sample bins the further reduction in volume is usually made by coning and quartering, or preferably by riffing and regrinding, until there is finally obtained the 4 or 5 lb. of pulp, dried and

crushed to 100 or 150 mesh, which goes to the assayer and chemist for valuation.

Plainly, the larger the proportion of the stream of ore taken for these successive cuts the greater the probability of accuracy; but here again expense and expediency are important factors. As an illustration: If each revolution of the machine took 90 per cent. of the stream, a 100,000-lb. lot would require approximately 95 successive sampling machines, with nearly as many recrushings to obtain the final 5-lb. sample. If 75 per cent. were taken there would be approximately 34 such sampling machines. It is hardly necessary to state that the cost of installation and operation of such a plant would be much greater than either the business or the necessity warrants.

SIZE OF CUT

It is from a realization of these conditions as well as from numberless experiments and comparisons of actual work that sampling men have decided on certain proportions which combine reasonable cost and accuracy. Such proportions vary from the one-half of coning and quartering, through the one-half to one-fifth of shovel work, to the one-fifth to one-tenth, or even less, of mechanical sampling methods. This proportion depends on several other considerations which I will not take up now; but in general the nearer the ore approaches uniformity in character, i.e., the less difference there is between the value of the richest and the poorest particle, the smaller the proportion which may safely be taken, whereas, with the so-called "spotted" ores of the gold camps it may not be safe to consider less than one-fifth, and then only after crushing the ore much finer than is required with the ores from the silver-lead camps. On certain low-grade sulphide ores which were first crushed to roasting size, it was learned that a satisfactory sample could be obtained by taking a 5-per cent. cut at one stage of the work.

Present practice is so to construct the machines as to take a certain fixed percentage of the stream, and, when considered advisable, to vary the conditions by finer or coarser crushing. No hard and fast rule can be laid down for this matter unless it is assumed in all cases that every ore sample is, say, of the most spotted variety; but unless the shipper is willing to pay the necessarily higher sampling charge for the finer crushing, such an arbitrary arrangement is not feasible.

DIFFERENT CONDITIONS REQUIRE DIFFERENT METHODS

In many cases in which smelting companies or milling companies treat exclusively the ores from their own mines and particularly those of very low grade, this sampling is not of very great importance; for if the method employed gives a correct average valuation at the end of a month or possibly a year, it satisfies all requirements, and what error is made on an individual lot may be balanced in some following lot or lots. Hence such works do not require elaborate appliances for sampling, and can even permissibly sample merely every fifth or tenth car as shipped from the mine, and thus avoid costly mills and elaborate and expensive cleanups between lots. There are numberless sampling plants in use in this country built on this principle and satisfying all requirements.

With custom smelting, milling, or sampling plants, however, there exists an entirely different set of conditions; for, whereas the buying concern may be satisfied to take a chance on the correctness

question very closely and had so laid out this work that even the position his men stood in and how they pushed the shovel into the pile was carefully planned, although details of his plan may have been unknown to the shoveler himself.

The first time I ran up against scientifically incorrect hand-sampling methods was in trying to account for large differences between what my company paid for the gold ores they were buying and what was reported by the concerns to whom we finally sold this ore. The details of these investigations may be of interest at a later time, but what I want to bring out now is that the investigations and tests proved so conclusively the unreliability of the hand methods, and the final outcry of the mine owner against them was so great that I doubt if, out of the million or so tons per month shipped from that camp, there is a pound of ore now being sampled by any but a mechanical system. And for the benefit of one contributor to this discussion I will add that this mechanical work is carried entirely through the bucking room even to the final division of the

wish to emphasize also that this mechanical division in the bucking room was in use by at least three sampling companies in 1896, and I could name many sampling mills which in the last 10 years have never used any other than the mechanical system at this stage.

It must be acknowledged that the mechanical systems adopted by some companies were fully as bad as the hand methods, and that some were so devised as to give a constant and pleasing percentage in favor of the buyer, and it is too much to expect that all such systems have been eliminated. As an instance, I know of a large mill using several machines in series, which, it is claimed, can be and are at times used in certain combinations which will take an excess of coarse, and at other times in other combinations an excess of fines. It is claimed that when the character of the ore is known, the superintendent of this plant can do the rest, that is, should he be *that kind of a superintendent*. But the fact remains that faults in construction and operation of a machine *can be located, proved and correction demanded* by any interested party, whereas, in all hand-sampling methods, the shoveler can continue one style of work, or can change it around with each shovelful, and although the onlooker may be positive that he has seen careless or crooked work, it is always a matter of dispute as to how this work really was done, as nothing less than a moving-picture machine can keep track of a man doing hand sampling.

POSITIONS OF SCOOPS IN PASSING SAMPLING MACHINE SPOUT

FUNDAMENTAL REQUIREMENTS OF MACHINE SAMPLES

The discussions of sampling have shown a wide and surprising difference of opinion in regard to some of the fundamental facts and necessary requirements of mechanical sampling, and it would be well could these principles be thrashed out. Some of the statements in the JOURNAL of Nov. 14 are entirely contrary to the facts, and show a fatal jumping to conclusions without proper investigation. For instance, the statement is made that all sampling machines are subject to a uniform error by the way the scoop passes under the stream of ore. To quote Mr. Church's statement exactly: "As the near side of the scoop passes under the area of the spout, ore of 2-in. size cannot fall into the sample until the edge of the scoop has passed 2 in. beyond the edge of the spout. This selective sampling is repeated as the scoop leaves the spout."

Let us refer to the accompanying sketches in which 1, 2, 3 and 4 represent the delivery spout and 5, 6, 7 and 8 the receiving sample spout of a mechanical sampler, which is moving in the direction of the arrow. Also let us assume that the greatest dimension of any piece passing through the spout is 2 in. Then as the distance *E*, in a properly constructed machine, is greater than the greatest dimen-

of the year's average sampling, the shipper of, say, 100 tons of \$100 ore is not content with returns of \$10 per ton *less* than this amount, merely because of the knowledge that the next shipper may have received \$10 *more* per ton than this following ore was worth. That is why custom plants have necessarily been obliged to pay more attention to and to make more investigations of sampling methods than a company handling merely its own ores.

DISADVANTAGES OF HAND SAMPLING

Hand sampling of ore, containing particles varying greatly in value, has for years and years been known to give a splendid opportunity for profitable, though often unostentatious, manipulation by the buyer. No man has ever been able to so build a cone, dump a wheelbarrow, or transfer ore with a shovel in sampling without starting a separation of the finer and coarser particles. The very knowledge and recognition of this unavoidable condition prevented many shippers from realizing that this same separation was often used to the continual advantage of the buyer, who had probably studied the

pulp over riffles and into the various sacks sent to the assayers.

SELECTIVE ACTION OF SCOOPS

This correspondent stated that he had found it possible to *eliminate entirely* the coarser particles from an ore by pouring it over an assayer's scoop. I can imagine no way for this to be done unless the ore is fed at a right angle to the sides of the scoop and from an inclined spout which would give the coarser a greater velocity than the fines. Then the position of the side of the scoop might be so raised or lowered as to allow the coarser to fall beyond and the fines to fall short of it. This would be incorrect practice, however, as the ore should be fed either vertically or in an inclined direction parallel with the scoop's sides.

In taking original and duplicate samples in the bucking room we pass the ore through riffles, taking one side for the original and the other for the duplicate. Some thousands of such comparative samples have shown no selection as above stated, either in value, in weight, or in separation of sizes as tested by screens. I

sion of the largest piece passing through the spout this 2-in. piece will fall into the sample spout even when the cutting edge has advanced 1 in. instead of 2 in., as claimed. But whether this is 1 in. or 2 in. is absolutely immaterial, as will appear later.

It is also claimed that on account of the positions *A* and *D* the sampler has a *selective* action and takes less of the coarser ore than it should. If this were the *whole* truth it would mean that the mechanical sampler invariably took a greater proportion of the fines than of the coarse presented to it, with rather terrifying results should there be great differences in value between the coarse and the fines. However, for the sake of argument let us grant the selection of positions *A* and *D*. Then it must also be acknowl-

I also think it is the consensus of opinion that a rapidly moving machine takes a more accurate sample than the slower one. As sampling is a matter of averages, or as I have suggested, fractional mixing, it seems plain that taking 30 samples per minute will give a more representative result than taking one per minute. There are bound to be interruptions of the stream of ore in a mill, and the slower the machine moves the greater the liability of letting part of the stream get by without representation, or of getting into the sample all that does come by during a slow revolution.

Suppose a lot of ore were spread out into a ribbon 6 in. wide and 1000 ft. long. Which plan would give the most representative sample? That which took out every alternate 100-ft. stretch, or that

satisfied that danger of error from this source is negligible.

As a source of error the fact that the cutting edges and sides of a machine have actual dimensions, whereas, theory calls for mathematical lines and planes can also be neglected. Such a refinement is absurd in the face of the whole matter's being one of averages, and of adjustment between the desired accuracy and allowable cost of plant and operation.

PRACTICAL RESULTS

I give in accompanying tables the details of two mixes, each of which is made up of 13 lots which were originally sampled during the last nine months. Owing to many of the samples being stored on an open platform, and having been sampled together during a heavy snow-storm, the dry weights do not check as closely as usual. In one lot in which the individual golds varied from 0.06 to 17.81 oz., and the silver from 1.55 to 3583.65 oz., the close checking of the average and actual assays of the mixture is very noticeable, although the *individual* assays for gold on the mixture pulp show large variations. These lots were all dumped indiscriminately into a hopper from which they were fed to a crusher and four sets of rolls. After each of the first three rolls the sample was reduced in volume by a Brunton oscillating time sampler taking approximately 20 per cent. The resulting sample was then halved by suc-

edged that in positions *B* and *C* the sampler selects a greater amount of the coarser ore, and that any error of *A* and *D* is corrected by *B* and *C*. It is unfortunate that this balancing was overlooked in the criticism referred to, for it may have led many readers, as it did one correspondent, to think that all sampling machines are built on an invariably incorrect principle.

The fact is, theoretically and actually, that *A* and *D* are balanced by *B* and *C*, and that the sampling would be just as correct were there a screen placed in the delivery spout and were the coarse and fines fed through different sides of the spout.

SPEED OF ORE STREAM

Again the amount of ore falling into the sample spout of any time-sampling machine depends entirely on the percentage of the whole time of revolution or oscillation that the sample spout is under the delivery spout. For instance, if in a Vezin sampler the cutting edges of the sample spout include an angle of 36 deg., it will take one-tenth, and if they include 90 deg., it will take one-fourth of the ore fed to it absolutely regardless of its speed of revolution. I would hesitate to mention such a truism, had I not been requested at times to increase the speed of the sampling machine in order to take a larger sample.

which took out every alternate foot? There is a limit to this speed, of course, one consideration being that the ore must be allowed to fall through the machine freely and not be knocked wildly about by the sides of the spout. Vezin claimed that he overcame this by feeding the ore through a spout inclined toward the direction of motion of the machine and so regulating the inclination of the spout and the speed of the machine that the particles of ore and the top edge of the spout would have the same forward speed when they met. I have watched and tested for long periods the action of machines on a vertical falling stream of ore and taking 40 samples per minute, and am

cessive riffings and grindings to the quantity needed for assaying, i.e., the sampling was mechanical throughout.

I do not wish to give the impression that I believe that the last word has been said in providing correct sampling methods. Baffling and unexplained differences will occasionally occur with everyone in the business; but in well conducted works the percentage of such cases is gratifyingly small. I have examined a large number of mills, and have had access to an almost nauseating number of comparative samplings and tests, and I am of the opinion that modern correct mechanical sampling is fully on a par with the assaying by which it is tested; that differ-

ences between successive samplings of a lot will generally be less than the variations of check assays on the individual pulps; and that the errors in sampling, or differences between samples and re-samples, are almost entirely due to faulty design or construction of the machine, neglect in repairing the cutting edges and keeping them to the designed shape, machines not working continuously, loss of fines through leaks in spouts, etc., lack of thorough cleaning between lots, "sloppy" work in bucking room proper, and, very largely, *insufficient crushing* as the weight of the sample grows smaller.

Vice-President, The Taylor
& Brunton Ore Sampling Company.
Salt Lake City, Utah, Dec. 22, 1908.

Acetylene Lamps for Mines

By A. CRESSY MORRISON*

For several years acetylene has been used in miners' lamps in France, Germany and Belgium to a large and steadily increasing extent, until at present it is used almost exclusively in more than 200 mines employing about 50,000 miners. The light is satisfactory, saves nearly 50 per cent. in cost and gives a better, brighter illumination than candles, or oil lamps. Mining engineers have been more or less familiar with this fact, but the introduction of acetylene into mines, up to the last two years, has been very slow in this country. Its use is now, however, commencing to be recognized as an important advance, and it promises in time to replace all other means of illumination, except in special cases.

Candles, which are largely used in Western mines, remove seven times and kerosene five times as much oxygen as does acetylene when furnishing the same candlepower. The products of combustion given off by candles are ten times and from kerosene nine times as much as that given off by acetylene. The difference is, therefore, enormous. While acetylene in a mine gives off no smoke whatever, every miner is familiar with the difficulty from the products of combustion given off by other illuminants. Acetylene, therefore, makes for the life and comfort of the miners, protects them from the degenerating effects of insufficient oxygen, and removes an important cause of lung and throat troubles. It has been found, in actual experience that in entries, which are 60 to 70 ft. ahead of the brattices or blower pipes, there is no smoke when an acetylene lamp is used and the entry is just as clear at the end of a shift as it is at the beginning.

An interesting thing about acetylene is the tenacity of the flame. It is not easily blown out; the rapid motion of the miner

will not cause it to flicker badly; and it burns brilliantly in an atmosphere so foul that the candles fade and go out. In fact, acetylene will not deprive the miner of light until the atmosphere is so bad that it will not support life.

For underground surveying and mine inspection, the use of acetylene is of great importance. Maps and note books escape the usual accompaniment of grease and smudge, while the acetylene flame with its reflector makes a good background for the blumb-bob string when surveying.

A large acetylene lamp and a strong reflector are useful about mines for throwing light into inaccessible places so that high backs, stopes, dangerous from caving, or other inaccessible parts of the mine can be examined.

Acetylene is especially advantageous as a cap lamp for drivers, and it has been found where mules are used that they can see much better and are not nearly so liable to stumble.

The bad quality of oil for miners' use, which has in some States compelled the passing of laws establishing a standard quality (laws, by the way, which are frequently violated by a species of adulteration which almost defies detection), is becoming another powerful argument in favor of the substitution of some illuminant which cannot be adulterated.

In actual practice, it has been found that 8 oz. of calcium carbide at 4c. per lb., or 2c. worth of carbide, will give nearly 10 c.p. of light for 10 hours, while candles in many parts of the country, counting four candles to the 10-hour day, would cost 5c. per day. There seems, therefore, to be no reason why acetylene should not be introduced provided a proper lamp at an economical price can be devised. As a matter of fact, practical experience has demonstrated that some of the miners' lamps now upon the market meet all the necessary requirements both as to economy, lasting quality, and practicability in use.

Miners' acetylene lamps are now frequently found in mines throughout the country, especially in Pennsylvania, New Jersey, and Illinois. The New Jersey Zinc Company, of New York, which has adopted acetylene illumination for all its mines, has probably more lamps underground than any one concern. The number of miners' lamps in use in the mines of this company is about 3000, and it has been found, in practical use, that the saving is at least 2c. per day for every miner.

The whole method of using acetylene is so simple and the lamps now in practical use are so satisfactory that the subject of better illumination in mines is worthy the attention of every mine owner and engineer; in fact, the obtaining of better illumination at half the cost, with greater output, safety, comfort, and, above all, with better health, to the user is so vitally important that the subject must be investigated soon by all mine managers.

The Zinc Ore Tariff Question

The Government's appeal from the decision of the U. S. Circuit Court for the Southern District of Texas in the zinc-ore customs case was heard at New Orleans on Jan. 5 before the U. S. Circuit Court of Appeals for the Fifth Circuit (Judges Pardee, McCormick and Shelby, circuit judges). The Government's side of the case was argued by former Assistant Attorney-General James C. Reynolds, appointed for this case as special assistant to the Attorney-General. The importers were represented by W. Wickham Smith, of New York. On Jan. 19 the Circuit Court of Appeals handed down the following opinion:

"Under the facts in this case it is not necessary to decide whether the provision for lead-bearing ores in paragraph 181, Tariff Act of 1897, is exclusive.

"On the merits the Board of General Appraisers and the Circuit Court ruled correctly.

"The judgment of the Circuit Court is affirmed."

The Board of General Appraisers held that the term "calamine," as mentioned in paragraph 514 on the free list in the Tariff Act of 1897, included the carbonates and silicates of zinc, and that blende ore should be admitted free of duty under Section 614 of the Tariff Act of 1897 as crude minerals, subject to the provision that, when any of the ores, carbonate, silicate, or blende, contained lead, a duty of 15c. per lb. on the lead contents only should be levied under Section 181. The Circuit Court affirmed in all respects the decision of the Board of General Appraisers, and this decision has now been again affirmed by the U. S. Circuit Court of Appeals.

The Treasury Department's estimate of the amount and kinds of money in the United States Jan. 1, 1909, is as follows:

	In Treasury.	In Circul'n.
Gold coin (inc. bullion in Treasury).....	\$176,291,097	\$ 619,317,841
Gold certificates.....	56,412,360	801,800,509
Silver dollars.....	1,219	72,443,563
Silver certificates.....	20,378,201	470,837,799
Subsidiary silver.....	18,162,747	135,003,363
Treasury notes of 1890.....	6,811	1,689,180
U. S. notes.....	10,258,047	385,422,969
Nat. bank notes.....	25,287,737	651,780,438
Total.....	\$306,801,209	\$3,092,315,703

Population of the United States Jan. 2, 1909, estimated at 88,200,000; circulation per capita, \$35.06.

The total amount in circulation shows an increase of \$13,326,405, as compared with Jan. 2 last year.

Northern Zambezia, South Africa, contains, according to Stephen J. Lett, in his pamphlet "More about Zambezia Minerals," many copper deposits and considerable gold; its coal deposits are extensive.

*Secretary-treasurer of the International Acetylene Association, 157 Michigan avenue, Chicago, Ill.

Patents Relating To Mining and Metallurgy

A Selected and Classified List of New Inventions Described during the Past Month in the Publications of the Patent Offices

UNITED STATES AND BRITISH PATENTS

A copy of the specifications of any of these patents issued by the United States Patent Office will be mailed by THE ENGINEERING AND MINING JOURNAL upon the receipt of 25 cents. British patents are supplied at 40 cents. In ordering specifications, correspondents are requested to give the number, name of inventor and date of issue.

ALUMINUM

MANUFACTURE—Improvements in or Relating to the Manufacture of Aluminum or Aluminum Alloys, and Silicides. Alf Slinding-Larsen, Christiania, Norway. (Brit. No. 25,408 of 1907.)

CALCIUM CARBIDE

PRODUCTION—Process of Smelting Metallic Compounds and Producing Carbides. Edgar E. Price, Niagara Falls, N. Y., assignor to Union Carbide Company, Niagara Falls, N. Y., a Corporation of Virginia. (U. S. No. 904,991; November 24, 1908.)

COAL AND COKE

COKE—Process for Treatment of Fuel-Coke. Harry L. Bruce, Portland, Ore. (U. S. No. 906,379; Dec. 8, 1908.)

FIREDAIMP—Method of Preventing the Liberation of Fireclay. Albrecht von Gröblich, Vienna, Austria-Hungary. (U. S. No. 906,572; December 15, 1908.)

RESPIRATORY APPARATUS for Use in Coal-Mines and Like Places. William E. Garforth, Normanston, England. (U. S. No. 908,239; Dec. 29, 1908.)

COPPER

BLAST-FURNACE PRACTICE—Apparatus for Handling Matte and Slag of Copper Blast-Furnaces. George K. Fischer, New Rochelle, N. Y. (U. S. No. 906,622; December 15, 1908.)

TUYERE—An Improved Construction of Copper Tuyere for Blast Furnace and Like Use. William J. Foster, Walsall, Staffordshire, Eng. (Brit. No. 3504 of 1908.)

GOLD AND SILVER

AMALGAMATOR and Concentrator for Ores and Tailings. John R. Harrison, Ballarat, Victoria, Australia, assignor of one-half to Hugh Victor McKay, Melbourne, Australia. (U. S. No. 909,293; Jan. 12, 1909.)

GOLD-DREDGE. Horace J. Clark, Chicago, Ill., assignor to Clark Dredge Manufacturing Company, Chicago, Ill., a Corporation of Maine. (U. S. No. 909,008; Jan. 5, 1909.)

PLACER-MINING MACHINE. Asa L. Corson, Pueblo, Colo. (U. S. No. 909,553; Jan. 12, 1909.)

TUBE-MILL. Harry W. Harding, New York, N. Y. (U. S. No. 909,292; Jan. 12, 1909.)

IRON AND STEEL

MANUFACTURING—Process of Manufacturing Steel. William R. Walker, Chicago, Ill. (U. S. No. 906,757; Dec. 15, 1908.)

SMEETING Method of Blast-Furnace Smelting. John W. Nesmith, Denver, Colo., assignor to Colorado Iron Works Company, Denver, Colo., a Corporation of Maine. (U. S. No. 910,480; Jan. 19, 1909.)

ZINC

EXTRACTION APPARATUS—Apparatus for Extracting Zinc. Edward H. Shortman, Bloxwich, England, assignor of one-half to the New Delaville Smelter Company, Limited, Spring Hill, Birmingham, England. (U. S. No. 907,416; Dec. 22, 1908.)

MINING—GENERAL

FUSE—Non-Explosive Fuse. Frank B. Cook, Chicago, Ill. (U. S. No. 905,503; Dec. 1, 1908.)

MINE SHAFTS—Improvements in Air Locks for Mine Shafts. Communicated from the Société Anonyme, John Cockerill, Seraing, Belgium. (Brit. No. 12,086 of 1908.)

MINE-TIMBER. Zachariah Z. Anschach, Silver Creek, Penn. (U. S. No. 907,554; Dec. 22, 1908.)

MINING METHOD—Method of Mining. Martin Schwerin, Elizabeth, N. J. (U. S. No. 904,021; November 17, 1908.)

RIVERBED DEPOSITS—Apparatus for Elevating Gold Bearing Deposits from River-Beds. Albert L. Eliel, San Francisco, Cal., and Oscar H. Eliel, La Salle, Ill., assignors of one-third to Lewis E. Aubrey, San Francisco, Cal. (U. S. No. 910,277; Jan. 19, 1909.)

ROOF SUPPORTS—Improvements in Mine Roof Supports. Frederick C. Kelghley, Uniontown, Penn. (Brit. No. 13,660 of 1908.)

ONE DIESSING

CONCENTRATION—Improvements in Apparatus for the Concentration of Pulverized Ore. Juan Gijeno, Begona, Vizcaya, Spain. (Brit. No. 11,702 of 1908.)

CONVEYERS—Improvements in Conveyors, Screens and the Like. Harry Bentley, Whitbytown, Cumberland, Eng. (Brit. No. 23,750 of 1907.)

CRUSHER—Cradle Crusher. Robert K. Donald, Victoria Road Loch, Victoria, Australia. (U. S. No. 909,562; Jan. 12, 1909.)

CRUSHERS—Hammer or Beater for Crushers and Pulverizers. Milton E. Williams, St. Louis, Mo., assignor to Williams Patent Crusher and Pulverizer Company, St. Louis, Mo., a Corporation of Missouri. (U. S. No. 904,908; November 24, 1908.)

CRUSHING-ROLL. Thomas L. Sturtevant, Quincy, and Thomas J. Sturtevant, Wellesley, Mass., assignors to Sturtevant Mill Company, Portland, Me., a Corporation of Maine. (U. S. No. 907,300; Dec. 22, 1908.)

CRUSH SEPARATOR. John C. Kirksey, Carthage, Mo. (U. S. No. 906,535; December 15, 1908.)

ORE SEPARATORS—Improvements in Centrifugal Ore Separators. Philip F. Peck, Chicago, Ill. (Brit. No. 3682 of 1908.)

STAMP MILLS—Improvements in Stamp Mills. Francis L. Matthews, Oakland, Cal. (Brit. No. 13,358 of 1908.)

METALLURGY—GENERAL

BLAST-FURNACE SLAG—Improvements in the Treatment of Blast-Furnace Slag. Henry K. G. Bamher, Greenhithe, Eng. (Brit. No. 2405 of 1908.)

DESLIPHURIZING ORES—Process of Desliphurizing Ores. Robert Hübner, New York, N. Y. (U. S. No. 906,883; December 15, 1908.)

ELECTRIC-FURNACE PRACTICE—Improvements in and Relating to Processes of Melting in Electric Furnaces and Their Application to the Extraction of Easily Volatile Metals. Henry Heerenschnidt, Paris. (Brit. No. 24,517 of 1907.)

ETRANSE—Furnace for the Reduction of ores. George F. Rendall, New York, N. Y., assignor to American Reduction Company, a Corporation of New Jersey. (U. S. No. 910,086; Jan. 19, 1909.)

SILVER-BRILLIANT—Method of Treating Electrolytic Slimes for the Recovery of Metals Therefrom. Alexander J. McNab, Trail, British Columbia, Canada, assignor of one-half to Walter H. Aldridge, Trail, British Columbia, Canada. (U. S. No. 908,005; Jan. 5, 1909.)

WELDING Improvements in Electrodes for Electric Welding, Soldering or Brazing. Communicated from the Electric Railway Improvements Company, Cleveland, Ohio. (Brit. No. 5017 of 1908.)

MINING MACHINERY AND APPARATUS

BORE-HOLES—Apparatus for Ascertaining Strike and Dip of Veins or Seams in Bore-Holes. Franz Melne, Berlin, Germany. (U. S. No. 908,209; Dec. 29, 1908.)

BORING Earth-Boring Machine. Charles L. Beltz, Selma, Cal. (U. S. No. 910,451; Jan. 19, 1909.)

DUMP-CAR—Two-Way Dump Car. Allen E. Ostrander, New York, N. Y., assignor to American Car and Foundry Company, St. Louis, Mo., a Corporation of New Jersey. (U. S. No. 909,209; Jan. 12, 1909.)

MINE CAGE SAFETY DEVICE—A New or Improved Safety Device for Mine Cages. Lits and Hugo Heron, and Wilhelm Merkel, Reimscheld, Germany. (Brit. No. 25,023 of 1907.)

MINE CAGES—Improvements in Automatically Operated Pences or Cages for Mine Cages, Hoists, Lifts and the Like Purposes. William Wilde and William Petrie, Thurnscoe, Rotherham, Yorkshire. (Brit. No. 26,809 of 1907.)

MINE-CAR COUPLING. Thomas C. Nation, Equality, Ill. (U. S. No. 908,880; Jan. 5, 1909.)

MINE-CAR STOP. Charles M. Henretta, Byeville, Ohio. (U. S. No. 907,350; Dec. 22, 1908.)

MINE-CAR WHEEL. John T. Parks and Madison T. Davis, Jr., Charleston, W. Va. (U. S. No. 909,112; Jan. 5, 1909.)

MINE-DOOR-OPERATING DEVICE. John W. Sausser, Osnaburg, Ohio. (U. S. No. 908,333; Dec. 29, 1908.)

ROCK-DRILLING ENGINE. John A. Traylor, Denver, Colo., assignor to the John A. Traylor Machinery Company, Denver, Colo., a Corporation of Colorado. (U. S. No. 906,250; Jan. 12, 1909.)

ROCK DRILLS—Improvements in Tool Collectors for Rock Drills. Gustave Jacques, Vielsalm, Belgium. (Brit. No. 9781 of 1908.)

SAFETY LAMPS—Safety Portable Manual Generator for Igniting Miners' Safety-Lamps. John W. Bowie and John H. Phelps, Cardiff, England, assignors to John Cunningham Bowie, Cardiff, England. (U. S. No. 908,386; Dec. 29, 1908.)

TUNNELING MACHINE. Joseph Retallack, Denver, Colo., assignor of one-half to John H. Redfield, Denver, Colo. (U. S. No. 906,741; Dec. 15, 1908.)

VALVE MECHANISM for Rock-Drills, etc. Joseph L. Mitchell, Denver, Colo. (U. S. No. 909,923; Jan. 19, 1909.)

WINNING-DRUM. Francis Donaldson, Pittsburgh, Penn., assignor to Ledgeswood Manufacturing Company, New York, N. Y., a Corporation of New York. (U. S. No. 909,708; Jan. 12, 1909.)

METALLURGICAL MACHINERY AND APPARATUS

CHARGING—Furnace-Charging Apparatus. Frank C. Roberts, Philadelphia, Penn. (U. S. No. 910,233; Jan. 19, 1909.)

CHARGING—Mechanism for Charging Furnaces. David Baker, Newton, Mass., assignor to the Brown Hoisting Machinery Company, a Corporation of Ohio. (U. S. No. 910,264; Jan. 19, 1909.)

CONCENTRATION Apparatus for Washing or Extracting Minerals. Reinhold Freygang, Hamburg, Germany. (U. S. No. 910,270; Jan. 19, 1909.)

CUPOLAS—Improvements in Spark Arresters for Cupolas and Like Furnaces for Melting Metals. Samuel Osborn and David Carnegie, Sheffield, Eng. (Brit. No. 1115 of 1908.)

FUEL—Fuel-Feeder for Furnaces. David F. Nisbet, Wilkesburg, Penn. (U. S. No. 910,305; Jan. 19, 1909.)

FUME-CONDENSING APPARATUS. Louis C. Laurent, Denver, Colo. (U. S. No. 907,375; Dec. 22, 1908.)

FURNACES—Improvements in Furnaces. Alfred W. Bennis, Eccles, Eng. (Brit. No. 26,471 of 1907.)

GAS PRODUCERS—Apparatus for Regulating the Supply of Fuel to Gas Producers and Other Combustion Appliances. Friedrich W. Sandmann, Dortmund, Germany. (Brit. No. 23,953 of 1907.)

KILNS—Improvements in Kilns for Burning Limestone, Dolomite and the Like. Ernst Schnatolla, London, W. C. (Brit. No. 17,609 of 1908.)

ORE ROASTER. Cyrus Robinson, New York, N. Y. (U. S. No. 908,425; Dec. 29, 1908.)

INDUSTRIAL CHEMISTRY

SULPHURIC ACID—Manufacture of Sulphuric Acid. Hugo Petersen, Wilmersdorf, near Berlin, Germany. (U. S. No. 904,147; November 17, 1908.)

SULPHURIC ACID—Method of Making Sulphuric Acid. Hugo Petersen, Wilmersdorf, near Berlin, Germany. (U. S. No. 908,696; Jan. 5, 1909.)

Personals

Mining and metallurgical engineers are invited to keep **THE ENGINEERING AND MINING JOURNAL** informed of their movements and appointments.

Walter Lewisohn has been chosen treasurer of the Tennessee Copper Company.

Robert N. Bell, of Boise, Idaho, is at Pioche, Nevada.

S. W. Mudd, of Los Angeles, Cal., is spending the winter in New York.

Willard S. Morse has resigned from the American Smelting and Refining Company.

James MacNaughton, general manager of the Calumet & Hecla company, is in New York.

Thomas Kiddie, manager of the smelter at Northport, Wash., was at Wallace, Idaho, recently.

Wm. Yolen Williams has returned to Spokane, Wash., after having spent several weeks in Nevada.

J. Parke Channing, it is understood, will soon retire from the presidency of the Tennessee Copper Company, but will remain a director.

Arthur Lakes, Jr., mining engineer, has moved his offices to Denver, Colo., where he will practice his profession.

R. M. Atwater, Jr., of New York, is making an extended examination of the Giroux copper mines at Ely, Nevada.

George E. Collins, manager of the Newhouse tunnel at Idaho Springs, Colo., has returned from a business visit to the East.

Dwight E. Woodbridge, of Duluth, Minn., consulting mining engineer, has been a visitor at the Lake Superior copper district.

Richard A. Parker, of Denver, Colo., has been examining mining property in the Nelson mining division of British Columbia.

A. H. Roller, manager of the Alice Development Company, at Idaho Springs, Colo., has returned from a business visit to the East.

William M. Gibson, assistant superintendent of the Calumet & Hecla, has left on a European tour and will be absent for about three months.

Superintendent Wilcox, of the Mass Consolidated Copper Company, is in the Wicks-Corbin district, of Montana, inspecting some mining claims.

S. S. Raymond, manager of the Britannia Smelting Company, at Crofton, Vancouver Island, B. C., left that place recently to visit New York.

A. B. W. Hodges, general superintendent of the Granby Consolidated, has returned to Grand Forks, B. C., from a two week's visit to Nevada.

H. S. Wierum, formerly with the American Smelting and Refining Company, has been appointed consulting engineer for the Lewisohn mining properties.

J. E. McAllister, general manager for the British Columbia Copper Company, Ltd., is to be in New York for a few days during the latter part of January.

H. Irving Jones, of Central City, Colo., has been appointed manager of the Hearne Gold and Copper Mining Company, operating in Gilpin county, Colorado.

W. A. Carlyle has left London, England, on a visit to Rossland, where, as consulting engineer, he will advise concerning the further development of the Le Roi mine.

Dr. James Douglas delivered an address before the mining students of the University of Wisconsin, Jan. 18, on "Some Metallurgical Recollections and Anticipations."

Dr. Malcolm Maclaren has left London for Kalgoorlie, Western Australia, to make, on behalf of leading companies, a detailed geological and economic examination of that field.

Frederick Burbidge has been appointed assistant manager of the Federal Mining and Smelting Company. He has been for some time manager of the Frisco Mining Company, Ltd.

Eustace M. Weston has resigned the management of the Rand Collieries, Ltd. (gold section), Brakpan, Transvaal, in order to enter upon the management of a large tin mine in Swaziland.

Edward Scallon has resigned his position as mining engineer with the Winona and King Phillip mines to accept one with the new Cole smelters soon to be erected in the Tooele valley, Utah.

H. P. Wherry recently returned from Mexico, and will be identified with the firm of Dickman & Mackenzie, of Chicago, as mining engineer. He has just gone to Magdalena, Sonora, to make some examinations.

H. L. Jene, who has been for three years with the Commonwealth Oil Corporation, Ltd., of New South Wales, has resigned his position. He was on the staff of the general manager as chief mine examiner and analyst.

A. A. Thomson, of London, who has been connected with the Steptoe Valley Smelting and Mining Company, at McGill, Nev., is now on his way to Katanga, Africa, whither he is going for the Tanganyika Concessions, Ltd.

Henry Snell, of Globe, Arizona, formerly superintendent of the Arizona Commercial, and now with the newly organized Superior & Globe Company, has been a visitor in the Lake Superior district, where he was called upon the death of his father.

Henry C. Schmidt has resigned the position of superintendent of mines with the Compania Metallurgia Nacional at Matchuala, Mexico, for the purpose of establishing an office at Monterey, Mexico, making a specialty of the operation and management of mining properties.

Hon. William Templeman will retain his position as Canadian Minister of Mines. A seat in Parliament has been found for him by the resignation of William Sloan, member for Comox-Atlin, B. C., and Mr. Templeman's return for that constituency is regarded as assured.

Samuel B. Sheldon, general superintendent of the Lackawanna Steel Company, Buffalo, N. Y., resigned Jan. 9, to accept the position of general superintendent of the Sacon works of the Bethlehem Steel Company. George F. Downs, heretofore assistant general superintendent of the Lackawanna company, has been appointed general superintendent in his place, and Thomas H. Mathias has been advanced to the position vacated by Mr. Downs.

Obituary

J. Stanley James, the well known consulting mining engineer, of London, died suddenly Jan. 10, in that city.

William G. Park died suddenly at his residence in Pittsburgh, Penn., Jan. 19. He was born in Allegheny, Penn., in 1849 and graduated from the Rensselaer Polytechnic Institute at Troy, N. Y. In 1873 he entered the firm of Park Brothers & Co., manufacturers of crucible steel, and after some years became the active manager of the works. The concern was reorganized as the Park Steel Company. In 1900 this company was the principal factor in the organization of the Crucible Steel Company, of America, and Mr. Park then retired; but in 1903 he was called into active service again and made chairman of the board, in which capacity he served until his death. He was thoroughly familiar with the manufacture of steel, and had much ability as an organizer and executive officer.

Societies and Technical Schools

Canadian Mining Institute—Preliminary notice has been issued of the eleventh annual general meeting, which will be held at Montreal, March 3, 4 and 5. Headquarters will be at the Windsor Hotel.

The provisional program of the meeting is as follows: Proceedings will be opened at 10 a.m., Wednesday by an address from the president. The Wednesday morning, and, if necessary, the afternoon session of that day will be devoted to the consideration of business submitted to the meeting, including the report of the council; the treasurer's statement; the proposed repeal of and amendments to the by-laws; and the election of council for the ensuing term. A selection of papers will be read and discussed on Wednesday evening, and at the Thursday and Friday sessions.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at
San Francisco, Butte, Goldfield, Salt Lake City and Denver

REVIEWS OF IMPORTANT EVENTS

San Francisco

Jan. 20.—The continued heavy rains which have been falling for the past 10 days have caused great damage in the upper portion of the State and some portions of the valleys have been flooded. Numerous railroad bridges have been carried away so that railroad communication has been stopped with many places. Several large dams of the electric power companies have been washed out and this has caused shortage of power supply at certain mining points. Three large dredgers have been wrecked. Gold dredge No. 2 of the Natomas Consolidated near Fair-oaks in the Folsom field turned turtle from the high winds. This machine cost about \$125,000, but it can doubtless be repaired for about \$20,000. The Indiana dredge at Oroville has also been wrecked and is supposed to be a complete loss. The National Gold Dredging Company's dredge on the middle fork of the American river has also been wrecked.

There was a heavy accumulation of snow in the high Sierra, especially near the summit where 12 ft. of snow had fallen. The miners hoped that continued cold weather would keep this as a storage supply for the streams and coming summer, but the very warm rains are melting this snow at the rate of 6 or 7 in. daily.

It is doubtless a fact that many of the debris dams of the hydraulic miners in the mountain and foothill region have been more or less damaged by the heavy flows of water in the cañons and smaller streams. Some of the slimes and tailings plants below quartz mines have been washed away entirely. Of course, great piles of tailings in similar situations have been carried away altogether.

In the action of the people against the Selby Smelting and Lead Company, the smelting company has filed a notice of appeal from the judgment entered against them on July 16. At that time the smelter was closed down by injunction owing to alleged damage to agricultural lands by smelter fumes.

Goldfield, Nevada

Jan. 19.—It is rumored that the Clark road will shortly have a preliminary survey made for the proposed road connecting Stonewall (a station 15 miles south of Goldfield) with Hornsilver, Lida, Palmetto and Silver Peak. This would give life to a number of low-grade properties in those localities, that without railroad facilities could not be operated at a profit

The payroll at Tonopah for the month of December was more than \$150,000; Tonopah Mining Company paid \$100,000 of this; Montana Tonopah, \$17,000; Jim Butler, \$4000; West End, \$5000; Mac-Namara, \$5500; Tonopah Extension, \$2500; Belmont, \$15,000.

In his annual report to Governor Dickerson, the State bullion-tax collector on Jan. 15 points out many evasions of mining companies, and recommends the enactment of a penalty clause that can be enforced. The report states that expense bills are much out of proportion to the amount of ore produced, and that some companies have charged operating expenses of leases that were operating at a loss though such losses in no way affected the resources of the parent company. The total tax collected on an output of \$10,-113,950 for the first nine months of 1908 was \$84,339.

Wallace, Idaho

Jan. 20.—A suit for the recovery of \$150,000 has been brought against the Frisco company by David H. Hyman, of New York. Mr. Hyman is president of the company, and the suit is primarily to foreclose a mortgage for the amount mentioned. It is claimed that on Oct. 1, 1907, the company borrowed from Mr. Hyman the sum of \$150,000 on a promissory note bearing interest at the rate of 6 per cent. and payable Jan. 1, 1909. It is further alleged that no part of the note has been paid and Mr. Hyman petitions that the mortgage covering all of the company's property given in security of the note be foreclosed. If this is done it is believed in Wallace that both the mine and mill will be operated again on a large scale.

A movement has been started among the mining men of the Cœur d'Alene to take a space at the Alaska-Yukon-Pacific fair and to place on exhibition a large collection of ore samples taken from properties of the district. A representative of the commission in charge of the exhibits at the fair is expected to arrive in Wallace some time this month to complete arrangements.

The sheriff of Shoshone county has received for service on the Bunker Hill & Sullivan Mining Company an order directing that it remove all stakes and monuments on claims which have been so laid out that they conflict with those of the Federal Mining and Smelting and allied companies. On the failure of the Bunker

Hill company to comply with this demand the Federal company states that it will use such force to remove the stakes and monuments as may be necessary.

Butte

Jan. 21.—The mines of the Boston & Montana company resumed operations on Jan. 18 after a shutdown lasting 10 days. At the annual stockholders' meeting of the British-Butte Company held here on Jan. 20 the following were elected directors for the ensuing year: M. H. De Hora, J. N. Kirk, W. E. Ward, Sam Barker, Jr., John F. Davies, H. A. Frank and J. W. Murphy. The report of Colonel De Hora, president and general manager, was read and approved by the stockholders.

In the action of the Montana Hardware Company against the Butte-Continental Copper Company, two of the stockholders of the latter company have asked permission to intervene and protect the company's interests, stating that the president of the Continental company, G. E. Blackburn, refuses to defend the action.

The directors of the Pilot-Butte Copper Company have called a special stockholders' meeting for Jan. 28, at which time the problem of how to meet the option payments for the company's property will be discussed. In the notice of meeting it is stated that two payments, each of approximately \$10,000, must be made during the present year or the option will be forfeited.

Salt Lake City

Jan. 22.—Samuel Newhouse has pronounced the Fink smelter an unqualified commercial success, and is at present in New York organizing a company to exploit the new process. It is said that John Hays Hammond and European capitalists will become interested in the organization. The experiments were carried on at Garfield near the Boston Consolidated mill in the plant erected by Mr. Newhouse. This plant has a capacity of 100 tons per day, and cost about \$13,000. It has been shown that the Fink smelter with 15 men on a shift and 25 h.p. and with less than two tons of fuel can smelt concentrates from the Boston Consolidated mill at the rate of 100 tons per day, turning out blister copper running from 95 to 98 per cent. On Jan. 17 blister copper was turned out in less than an hour after charging the concentrates into the furnace. This is the first furnace ever invented that will make blister copper direct from ore.

The annual meeting of the Daly-West Mining Company will be held at Denver, Feb. 15; a fight is being waged by certain stockholders of the company to remove the present management and prevent the company from being merged with the Daly and the Ontario companies. There are 180,000 shares outstanding.

At the Utah Copper Company's property, the ground is being worked for over a mile in length with seven steam shovels in operation. The two main pits are now being connected, and when this has been accomplished, in place of loading cars singly, an entire train can be loaded at once. From Pit B two and one-half million tons of copper ore have already been mined. At the edge of this pit is a face of ore 230 ft. high. A little blasting at the foot of this cliff breaks down large quantities of ore. The orebody is 2000 ft. wide, and at present in furnishing the mills with 6000 tons of ore per day. The present mining cost is said to be less than 20c. per ton. In addition to the enormous surface development, considerable underground work is under way. C. M. MacNeill, president, J. R. Babbitt, general counsel, and J. D. Hawkins, general manager, of the United States Refining and Reduction Company, of Colorado, and C. C. Hamlin, a prominent Colorado lawyer and politician, have been visiting the property of the Utah Copper Company at Bingham and Garfield. A report is now being compiled by the officials of the company.

The Sioux Consolidated Company has posted a dividend payable Jan. 20, of 8c. per share on the 745,380 shares issued, or a total of \$59,631. At the recent annual meeting it was shown that there was \$73,000 in the treasury with considerable ore unsettled for. This property paid its first dividend last October; dividends were also paid in November and December, so that during 1908 this company paid 17c. per share, or \$126,716. Many people question the ability of the mine to keep up this rate of production.

The Uncle Sam Consolidated Company, another Tintic producer, has passed the January dividend, and it may be several months before dividends are resumed. This is due to the fact that the mining at present is in one of the lean streaks characteristic of Tintic. John Dern, before going to Nebraska, stated that while the mine did not have as much shipping ore as usual "in sight," that the vein was as strong as ever. Development work is being pushed, as the company has considerable money in the treasury.

The Tintic smelter is smelting again at full capacity, as No. 3 lead furnace is in operation. The copper furnace has been held back considerably by slow delivery of structural steel, but it will be ready for operation soon. The recent delay was due to the breaking of the pump that fed the water jackets of one of the furnaces and was not due to the breaking of the

station pump at the Swansea mine. The smelter is now taking power from the Telluride Power Company. Shippers have been notified to resume shipments to the smelter as everything is running smoothly.

Denver

Jan. 23.—In the Breckenridge gold-placer district, Ben. S. Revett, manager of the Reliance Mining Company, has remodeled his steam dredge, and altered it to use electricity, getting his power at present from the Central Colorado Power Company; but it will eventually be furnished by the Consolidated Mining and Electric Company (the old Gold Pan power plant) from Spruce creek, on the upper Blue river. The dredge's capacity is about 2500 cu.yd. per day, and it is believed by those who know that it will make a success. The Colorado Gold Dredging Company, with two dredges, the first that have achieved a marked success in this district, has been dredging during the season at a cost of 8c. per yd., everything included; and as nearly as can be ascertained, the average saving is from 12 to 14c. The capacity is 3000 cu.yd. in 24 hours. A fourth dredge has been moved from Clear creek, near Golden, into this district, and is a 5-ft. close-connected bucket type, with a capacity of about 2500 cu.yd. per diem.

A gold dredge of 2000 yd. capacity was installed last fall on Green river, close to the Colorado-Utah line, and near the projected line of the Moffat road. A trial run was made before winter closed in, and it is stated that the saving was from 30 to 40c. per yd. The owners have 1190 acres of placer claims, besides two power sites.

A 300-bbl oil well has been struck at Boulder by the Inland Oil Company, and a good deal of excitement prevails, leases having been taken for 8 to 10 miles around. Refined oil is being shipped from Boulder at the rate of 360 cars monthly.

The Eastern Colorado Power Company, a subsidiary concern to the Central Colorado Power Company, has let a contract to the Karns Rotary Tunnel Machine Company, for 600 ft. of tunnel through granite between the Power company's intake and outlet near Magnolia, on Boulder creek. The machine cuts a 6-ft. diameter bore. The same company has also announced in the daily press that a contract has been let to the MacArthur Construction Company, of New York, to build a dam in Boulder county to cost \$600,000. It is designed to impound 500,000,000 cu.ft. of water, and will be built of concrete. The lines from the first section of the Shoshone plant, near Glenwood Springs (18,000 h.p. capacity) will connect at Denver with the line from the Boulder plant (21,000 h.p.), thus supplying a large

amount of power for the needs of the city of Denver.

The diamond-drill hole from the breast of the Yak tunnel, at Leadville, tapped the Resurrection mine this week, and the water from this immense property is now being rapidly drained through the tunnel. The Resurrection was leased by the owner, D. H. Moffat, to the Yak company, and will be operated by it through its tunnel.

Professor George, of the University of Colorado, at Boulder, and director of the State Geological Survey, has issued a report of the progress of his survey during the past two years. This includes the survey and mapping of 110 sq.m. in the Hahns Peak region, and about 90 sq.m. of the Boulder county tungsten belt; and 22 sq.m. of the Montezuma area in Summit county have been mapped topographically and geologically. A complete topographic and geological map of the State is also nearing completion.

Toronto

Jan. 23.—The rush to Gowganda, in spite of the season, continues undiminished, and considerable hardship has resulted owing to the lack of accommodation and the crowding in of numbers ill prepared to encounter inclement weather. Three prospectors were recently found frozen to death in a tent near Gowganda, and others have undergone much suffering. The mining recorder at Elk Lake has been so overwhelmed with business that there has necessarily been much delay in recording applications. The Government recently sent several assistants to enable him to overtake the work. Building is going forward rapidly and material and provisions are being sent in as fast as possible. The provincial government has set aside a tract of land of about 1000 acres at the north end of Gowganda lake as a townsite. Squatters have been warned off and as soon as plans can be made the lots will be sold by tender.

Frank Law, the Toronto broker charged with conspiracy to defraud in connection with the flotation of the Highland Mary and several other mining companies, whose case has been repeatedly postponed, was brought to trial last week and found guilty. Law's counsel gave notice of appeal on the ground that Law had been promised immunity. Sentence was suspended until the appeal is decided.

Paul Neuman, of the Apex Underwriters Syndicate, pleaded guilty yesterday to technical violations of the clauses of the Ontario Companies Act regarding prospectuses and was fined \$200 on the first charge, and \$10 on the second. Mr. Neuman stated that he had no intention of violating the law, and had submitted the advertisements complained of to a legal expert on company law who assured him that they were not illegal.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Arizona

COCHISE COUNTY

Modern Copper—It is reported that this property was sold last week to the Boston-Bisbee company.

GILA COUNTY

Globe—In accordance with a notice signed by Superintendent R. B. Hegardt and posted Jan. 24, all the mines of the Old Dominion Company closed down at two o'clock Sunday morning, to remain closed indefinitely. The Globe Consolidated, Arizona Commercial, Superior & Boston, Miami and other companies sustained the Old Dominion Company's action by also suspending work yesterday. A few agitators in the union have been stirring up discord for some time, but the decision of the Old Dominion Company to close its mines was caused by offensive acts of walking delegates.

GRAHAM COUNTY

Clifton-Morenci District—The Shannon Copper Company recently secured a controlling interest in the Clifton-Northern railroad and will operate it in the future. The company is laying a three-rail track to the New England ore bins in North Clifton. The greater portion of the New England and Copper King ore is being shipped to the company's smelter. The company has also purchased valuable limestone claims up the San Francisco river. The local management of the company has received instructions to begin work on the Shannon-Arizona railroad, which will be built from the Shannon smelter to the mines at Metcalf. The road will be built high in order to avoid the annual Chase creek floods. It is proposed to extend the road to the Garfield district, where the company owns property.

PINAL COUNTY

Kelvin-Calumet—At a meeting of parties interested held in New York City, the control of the Kelvin-Calumet was sold to the Lewisohns, J. Parke Channing and the General Development Company. The property will be acquired by a new company, to be known as the Ray Consolidated Copper Company, which will have a capital of 1,000,000 shares of the par value of \$5 each, and \$2,000,000 6-per cent. convertible bonds.

California

CALAVERAS COUNTY

The warm rains have helped out the

water supply of the mines in this county, the previous shortage having been due to the cold weather, which froze up the ditches. The Utica mine at Angels, after several weeks idleness, has started operations again.

Reiner—At this mine, San Andreas, crude petroleum applied on the green wood in use has enabled them to produce abundant steam without change in the furnaces. The blue gravel channel has been reached. Machinery is being hauled in and the mill will soon be ready for operation.

EL DORADO COUNTY

Independence—Owen, Hill & Schafsky are putting up a two-stamp mill on this mine where they recently uncovered a very rich pocket. The vein is small but the rock is exceptionally rich.

Patterson—Work has been resumed on this mine at Indian Diggings by Fred and John James.

MARIPOSA COUNTY

Egenhoff—This group in the Merced river cañon on the line of the Yosemite road a mile from the old Hite mine, is now the property of A. B. McKee, of Chicago. There are seven claims in the group, four of which are being worked. There is a 10-stamp mill and other necessary equipment on the property. The capacity of the mill is to be increased and the mine worked on a larger scale than formerly.

Green Mountain—This copper mine, owned by Capt. Sydney, will hereafter ship its ores to the Globe smelter. New machinery is to be installed.

NEVADA COUNTY

Blue Lead—This famous old gravel mine at Relief Hill has been bonded by James Graham, of Modesto and J. V. Snyder, of Nevada City, and operations will shortly be resumed. The bedrock tunnel tapping the gravel channel is 2700 ft. long. The men at present are working in an upraise.

Midas—At this mine near Rough & Ready district, Herbert James superintendent, a good strike has been made. This is one of the newer mines of the county, having been discovered two years ago.

PLUMAS COUNTY

John Salsbery, of Tonopah and J. E. Hall have bought the Hobson, Dewey and

Blackjack properties from Wm. Stampfli, and the Soda Creek placer from Wm. Hall. They have also acquired the Plumas National mine.

SHASTA COUNTY

Balaklala—The smelter is treating about 1200 tons daily of Balaklala ore and about 150 tons of Trinity ore, and is producing upward of 1,500,000 lb. of copper per month. The ore is said to be yielding 48 lb. of copper per ton. The smelter has four MacDougal roasting furnaces, three blast furnaces and one reverberatory.

SIERRA COUNTY

Telegraph—There are now 30 men at work in this mine taking out gravel to be washed when there is sufficient water supply.

SISKIYOU COUNTY

Hogan—At this mine on Taylor creek a vein of very high-grade ore has been found near the surface and specimens are being sacked.

TRINITY COUNTY

Yellow Jacket District—Seven of the groups of mining claims in this district will be worked all winter, something it is not customary to do.

TUOLUMNE COUNTY

Jupiter—In this mine near Jacksonville, owned by E. R. Bolton, a wide ledge has been met carrying free gold and a high percentage of valuable sulphurets.

YUBA COUNTY

Blue Point—Superintendent E. W. Tarr reports that considerable machinery for this mine is being made and that as soon as certain changes have been made in the machine for building the ditch, excavation work will be resumed.

Colorado

TELLER COUNTY—CRIPPLE CREEK

Drainage Tunnel—Good progress is being made on this tunnel from the portal heading; it has reached a point nearly 4700 ft. in. A considerable flow of water was recently encountered, which checked the progress of the work slightly for a few days, but at the present writing the water-course has been passed and the tunnel is comparatively dry once more beyond it. The workmen on the tunnel are after a record for tunnel driving this month. No work will be done in the headings of the

intermediate shaft until a new compressor can be installed. The work on the tunnel is being done under contract by A. E. Carleton, of Cripple Creek. James McIlwee, also of Cripple Creek, has charge of the work at the tunnel.

Cripple Creek Mine Owners' and Operators' Association—The annual meeting of this association was held in Colorado Springs last week and all of the old board were reelected to serve for the ensuing year. These are as follows: Sam McDonald, superintendent of the Strong mine; E. H. Beebe, superintendent of United Gold Mines; R. P. Windsor superintendent, of Elkton; E. J. Trevarrow, superintendent, of Vindicator, and G. E. Copeland, general manager of Copeland Sampling Company. It is understood that an effort will be made to have a bill passed the legislature making it a felony to buy stolen ore.

Golden Cycle—This company will install a large new hoisting plant on the main shaft of the Cycle workings, thus enabling the mine to make a much greater production. The new hoist will be of the direct-connected type, and is manufactured by Webster, Camp & Lane, of Akron, Ohio. The hoist will be good for 3000 ft. depth. In the meantime the mine is making a steady production. H. McGarry, of Colorado Springs, is general manager, and J. T. Milliken, who was formerly consulting engineer of the mill at Colorado City, is now to be consulting engineer of all the Golden Cycle interests, including the mine, mill and coal lands.

Portland—A new roaster has been installed in the mill of this company at Colorado City, increasing the capacity to such an extent that it is able to do some custom milling, and is in the market for ores from this district. A small plant has been erected at the mine in the district to experiment on the treatment of the low-grade dump ores, of which there is a large quantity. The regular quarterly dividend of 4c. per share was declared this week.

GILPIN COUNTY

Anchor—A controlling interest in this property has been sold to William H. Hearne, of Wheeling, W. Va., who has assumed the presidency of the Hearne Gold and Copper Mining Company. About 50 tons of ore per day are being shipped since the tramway made connections to the mines.

Aztec Mines Company—Arrangements are being made for the installation of an 80-h.p. boiler and also for a larger hoisting plant, with intention of sinking the shaft several hundred feet. H. Irving Jones, Central City, is manager.

German Uranium Mining Company—Philadelphia people are interested in a lease and bond on the German and Leone properties, and they are installing a plant of machinery and will put in an air compressor at an early date. W. Knutzen, Bald Mountain, Colo., is manager.

Gilpin-Boulder Consolidated Mines Company—A new shaft building is being erected on the Poole claim, and a steam plant is to be installed. E. H. Crabtree, Central City, Colo., is manager.

Gilpin County Land and Mines Company—This company has purchased for a reported consideration of \$10,000 the Colorado lode in Russell district, and it is reported that it is arranging for its transfer along with adjoining property to Eastern buyers.

Rockford—This mine in Russell district has been sold to Henry P. Lowe, of Denver, and S. T. Harris, of Russell Gulch, Colo. Milling ore 8 ft. wide and of a good grade has been opened up in sinking and machinery is to be installed. S. T. Harris, Russell Gulch, Colo., is in charge.

Rome-Gardner—Rome, N. Y., people are interested in this claim, and they are having an examination made. Leasers are taking out some good ore, but it is expected that the company will arrange for heavy developments and will require heavier machinery. A. Watters, Bald Mountain, Colo., is manager.

Senator—Chicago people have become interested in this mine near Black Hawk; a company is being organized and arrangements are being made for development. Company office is at 121 La Salle street, Chicago.

LAKE COUNTY—LEADVILLE

Ball Mountain Tunnel—The management states that within 30 days this tunnel will reach the Sunday vein, 2300 ft. from the portal; the tunnel is being driven at the rate of 9 ft. per day.

Big Six—Prospecting is being carried on in new territory on Breece hill to the northeast from the 750-ft. level with some success. The ore found runs well in gold, but so far it is only in patches. Sufficient ore is being taken out to pay the running expenses, and as long as this continues prospecting will be continued in the new territory.

Yak Tunnel—The water in Resurrection shaft No. 3 has been tapped and is being lowered at the rate of 1 ft. per day. No chances were taken with tapping this large body of water; drill holes were driven to it 50 ft. in advance of the tunnel and into one of the drifts, which is 35 ft. below the level of the tunnel. The water is now being forced through the holes. The tunnel is being driven ahead at the rate of 12 ft. per day.

Illinois

Illinois Coal Operators' Association—At the annual meeting last week, the following officers were chosen: President A. J. Moorshead, Madison Coal Company; vice-president, F. W. Lukens, O'Gara Coal

Company; secretary and treasurer, E. T. Bent, Oglesby Coal Company. The selection of a commissioner to succeed the late Herman Justi will be made by the executive committee.

Idaho

SHOSHONE COUNTY

Merrimac—A strike of 13 in. of clean shipping galena ore has been made at a depth of about 50 feet.

Curney Copper—A report of the company's affairs has been issued showing that during 1908 about 650 ft. of work was done. About 122,000 shares of treasury stock was disposed of netting the company \$13,287, while the total receipts aggregated \$17,748. Altogether the company disbursed \$18,301, leaving a small in debtedness.

Temple Mining Company—At a meeting of the directors held in Wallace this week it was decided to levy an assessment of five mills a share with which to prosecute development work.

Wallace M. M. & R. Company—At the annual meeting of stockholders held in Wallace, the following officers were elected for the ensuing year: President, L. Dols; vice-president, George Evans; treasurer, Herman J. Rossi; secretary, Gary C. Burke; directors, J. W. Evis, J. F. Gilson and William Fagan. The secretary's report shows that about 250 ft. of work was done during 1908. A resumption of work at the mine will not be made until the spring.

King of Pine Creek—The strike recently made in this property has now widened out to about 7 ft. of ore of a concentrating quality. Development work will be pushed throughout the winter.

Kentucky

HENDERSON COUNTY

Southern Coal and Transportation Company—This company, which recently bought 8000 acres of coal lands, has begun work opening a mine, and has let contracts for machinery to handle an output of 2500 tons daily. J. W. Miller, Robard, Ky., is manager.

Montana

BUTTE DISTRICT

Butte & London—At the regular annual meeting of stockholders held on the 10th, the following were elected directors for the ensuing year: Frederick W. Baker, James Talbot, James H. Lynch, A. A. McMillan, Fred Whiteside, Charles J. Kelly, F. J. Anderson, W. W. McDowell, Guy W. Stapleton, T. H. Emery and W. E. Reynolds.

Butte & Ely—At the regular annual meeting of stockholders the following were elected directors for the present year: R. M. Hodgins, J. C. Adams, B.

E. Calkins, Dr. T. B. Moore and A. L. Longley. At the directors' meeting held immediately afterward R. M. Hodgins was elected president, B. E. Calkins vice-president, and A. L. Longley treasurer.

Butte & Yerington—At the regular annual meeting of stockholders the following were elected directors for the present year: W. C. Siderfin, J. N. Kirk, J. C. Adams, J. H. Case, Dr. T. B. Moore, W. E. Right and B. E. Calkins. At the directors' meeting officers were elected as follows: W. C. Siderfin, president, T. B. Moore vice-president, W. E. Wright secretary and treasurer.

Copper Eagle—The management states that favorable results have been met with in the development work now being carried on at the 350-ft. level, the work showing the same three orebodies which were opened up on the 250-ft. level. Manager Corry states that in sinking the shaft an independent shoot of heavy sulphide ore was encountered, which showed 1.5 per cent. copper, 281 oz. silver, \$3 gold per ton.

BUTTE DISTRICT

Butte Coalition—Present production is 2,500,000 lb. per month. The 16th level crosscut, Tramway shaft, has cut the extension of the main orebody of the Minnie Healey mine.

Michigan

COPPER

Ahmec—The rock now being milled is yielding 24 lb. of copper per ton. When the two new shafts are completed a year hence the whole stretch of the company's holdings on the Kearsarge lode will be commanded, and an output of 14,000,000 lb. of copper per annum is eventually expected.

Hancock—Sinking continues at No. 2 shaft of this company at the rate of nearly 100 ft. per month, several lodes traversing the tract. It is calculated the Hancock lode will be intercepted at 2200 ft., and the main workings of the Quincy at 3600 ft. The shaft is below the 14th level. The main working crosscut at the 13th level to connect with No. 1 shaft will be holed through in a short time. This crosscut will handle all the rock from the working of No. 1 shaft.

Quincy—The new Pontiac shaft of this company is down 200 ft. with copper in evidence all the way. A rock house is to be erected in the near future.

Ojibway—No. 1 shaft of this company has reached the 650-ft. level and a station is being cut preparatory to crosscutting. The lode was opened near the shaft at the 500-ft. level. The crosscut from this same level of No. 2 shaft is at the point of intersecting the lode.

Challenge—This company has concluded all development at the exploratory shaft with the exception of one diamond drill,

which is operating in the eastern crosscut. Nothing of any commercial value has been found in developing.

Superior—Sinking has been resumed in No. 1 shaft below the 10th level, where it was bottomed when sinking was temporarily suspended while a portion of the shaft was widened to accommodate the two skip roads. The new hoisting engine and compressor have gone into commission and the smaller engine moved to the site of No. 2 shaft.

Wyandot—This company has done about 125 ft. of drifting on its newly opened amygdaloid lode and the same copper-bearing formation continues.

Copper Range—This company has started its third diamond drill on the land it has under option from the St. Mary's Mineral Land Company. Two parallel cross-sections will be made of the tract. At the Globe tract a crosscut has been drawn to the lode 356 ft. from the surface but the same unsatisfactory conditions exist as at the 1000-ft. station.

Mohawk—Sinking continues in all five shafts. Underground conditions are up to the average with plenty of ground opened to keep the mill running to its capacity. Nos. 1 and 2 shafts are down to the 16th level; No. 3 to the 11th; No. 4 to the 12th; and No. 5, the newest of the openings, below the 8th level. It is planned to start a new shaft No. 6, in the spring about midway between No. 5 shaft and the southern boundary of the property.

Wolverine—This company has installed electric pumps in its two shafts. At the stamp-mill the Jackson sand-conveying system will soon be ready to run. This system will deposit the tailings at a distance of about 800 ft. from the mill.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Red Top Consolidated—A 64-ton shipment, having an estimated value of \$7000, was made to the Western Ore Purchasing Company Jan. 15. Eight carloads have been shipped since Jan. 1, all but one of which returned over 5 oz. gold per ton; that one carried 4.8 oz. gold per ton.

Butterfly Group—The five claims in this group on Knickerbocker mountain, about four miles east of Goldfield, was purchased last week by J. O. Buckley, of Milwaukee, for the Nevada & Eastern Mining Company. As yet no development work except the annual assessment work has been done on the property.

Simmerone—It is reported that work will be resumed on company account. Three years ago the property created quite an excitement by shipping high-grade ore to the extent of \$15,000. But the shoot was lost at a shallow depth; and although the shaft was continued to a depth of 250 ft., and considerable crosscutting done, the oreshoot was not found again.

Combination Fraction—The lower portion of the shaft has been retimbered and a cage put in to take the place of the bucket and crosshead formerly used; a large pump is also being installed. With these improvements and the large ore reserves now blocked out, a steady production is promised.

Commonwealth—The Commonwealth Mining and Leasing Company on Jan. 14 made its first shipment; this amounted to 18 tons. The property is two miles east of Goldfield, and should return from this lot be favorable and regular shipments be made, development in that portion of the district will be encouraged.

Hazel Goldfield—As work advances to the south a steady improvement is noticed both in the width and the value of the ore. Shipping ore is now exposed in every heading, the better values being next to the hanging wall in a streak from 6 to 20 in. wide; the rest of the vein is of milling grade. As a large amount of water has been struck, a pump will be installed.

Five Friends Lease—This lease which adjoins the Hazel on the north, in crosscutting for the Red Top vein from the 250-ft. level, has recently cut a high-grade orebody.

Nancy Donaldson—As returns from several small trial shipments of medium-grade ore, taken from shallow shafts sunk on this property, were favorable, three miners are now prospecting the ground to determine the best location for a deep shaft. On determining the best point for it, three shifts will be employed and a gasoline hoist installed to expedite sinking.

Kansas City Velvet Lease—A shipment of nine tons was made from this property Jan. 16. This ore occurs in small lenses; the main shoot has not yet been found.

ESMERALDA COUNTY—HORNSILVER

Great Western—This property is shipping to Cuprite by wagon 12 tons per day. The drift on the 300-ft. level is being extended east to cut the oreshoot worked on the upper levels. In the west drift on the 200-ft. level ore has been found carrying over 2 oz. gold per ton.

ESMERALDA COUNTY—SILVER PEAK

Pittsburg Silver Peak—From March 1 1908, to Jan. 1, 1909, the mill ran at nearly full capacity with an average monthly output of 10,000 tons showing a value of \$10 per ton; the extraction is 93 per cent. About 200 men are employed at the mine and mill; the average wage is \$5 per day. The ore is transported to the mill by an aerial tram; an automatic weighing machine is now being installed at the mine. Many surface improvements are under way, including a two-story bunk house at the mine; the lower floor of this is to be fitted as a club house for the miners.

ESMERALDA COUNTY—LONE MOUNTAIN

Teton Group—Rogers and Tedford, the owners of this property on the east slope of Lone mountain, have sent to the mine a wagon train of supplies and will sink the shaft, now 40 ft. deep, to a depth of 200 feet.

NYE COUNTY—BULLFROG

Homestake-Kings—This property on Jan. 10 shipped the December clean-up, \$10,000 in gold bullion, to the Mint. The management states that the property produced more than \$40,000 in 1908.

Pioneer Mine—A carload of ore was shipped to Salt Lake City Jan. 7. Stopping on the high-grade ore is progressing in the sub winze with no change in the value of the ore. The shaft is now 200 ft. deep; a station will be cut at a depth of 210 ft. and a level run to develop the orebody.

Shoshone—A third shift has been put on in the crushing department of the mill which is now running to full capacity. Fourteen bars of bullion, valued at between \$30,000 and \$35,000, were shipped Jan. 14; these represent the December clean-up from the zinc boxes. The concentrates in the future will be reground and cyanided so that only bullion will be shipped.

NYE COUNTY—TONOPAH

During the week ending Jan. 9 the Tonopah Mining Company mined 3050 tons; Belmont, 600 tons; Jim Butler, 300 tons; Midway, 100 tons; West End, 150 tons; MacNamara, 250 tons; and Montana Tonopah, 720 tons of ore.

Belmont—On the 1100-ft. level a large tonnage of fine ore has been blocked out. A raise from the west drift of the 1100-ft. level shows a vein 10 ft. wide in which occur streaks and bunches of high-grade ore; 70 ft. east of this, a raise from the east drift has exposed 5 ft. of ore of good milling grade. This ore has been proved to the 1000-ft. level. In the west drift on the 1000-ft. level a winze was sunk and a drift run to the east which shows 5 ft. of milling ore in the face; this is 275 ft. west of the raise from the west drift on 1100-ft. level. Whether these orebodies are in the same vein or not has yet to be proved.

Montana - Tonopah—Two important strikes were made in this property last week, both finds being in the rhyolite-dacite formation. The first was made on the 465-ft. level where a continuation on its dip of the Triangle vein was cut in the west crosscut at a point 300 ft. west of the shaft. The orebody is 2½ ft. wide and is of good milling grade. The second strike was made in a crosscut on the 515-ft. level and shows 8 ft. of milling ore, this also is in the Triangle vein.

MacNamara—On the 200-ft. level in the drift which was turned so as to run south in order to find the vein which was faulted

in the drift, ore was found after driving 60 ft. south. The vein is 8 ft. wide showing 2 ft. of milling ore on both hanging and footwall with low-grade quartz between. The west drift on the 275-ft. level cut into ore last week; the face shows 5 ft. of milling ore.

Tonopah Mining Company—The mill reported an average of 92 stamps dropping continuously last week; 2950 tons of rock assaying \$25.25 per ton were crushed; 58 bars of bullion valued at \$795 a bar and 46,000 lb. of concentrates were shipped, making a total production of \$57,495 for the week.

NYE COUNTY—HANAPAH

Silver Glimpse—The Conrad & Lain lease on this property, 18 miles east of Tonopah, recently shipped 36 tons which returned very close to \$100 per ton. Ore for a second shipment is now being hauled to Tonopah.

WHITE PINE COUNTY

Nevada Consolidated—The Steptoe Valley works now consists of three units of 1333 tons capacity each. Two of these are being increased by 20 per cent., and a fourth is being added, all of which is for treatment of Nevada Consolidated ore. When completed (next April) the works will be of 6000 tons daily capacity, of which 2000 will be for Cumberland-Ely and 4000 for Nevada Consolidated. This should give the latter capacity for producing about 50,000,000 lb. of copper per annum. Nevada Consolidated is already producing its copper at a low cost, and is expected eventually to produce at 7c. per lb. for operating charges, or say 8½c., including amortization and all charges.

Giroux—The affairs of this company will hereafter be directed from the Duluth office of Thomas F. Cole, although Joseph L. Giroux will retain the presidency. Mr. Cole is said to agree with Mr. Giroux in belief as to the possibilities of the Alpha shaft. The property will now have a more vigorous development.

Pennsylvania

ANTHRACITE COAL

Philadelphia & Reading Coal and Iron Company—This company's statement for November and the five months of its fiscal year from July 1 to Nov. 30 is as follows:

	November.	Five Mos.
Earnings.....	\$3,187,764	\$13,761,808
Expenses.....	3,385,928	13,005,877
Net earnings.....	\$ 271,836	\$ 755,926

For the five months there were decreases of \$3,501,759 in earnings; of \$2,803,113 in expenses; and of \$698,646 in net earnings.

BITUMINOUS COAL

Union Connellsville Coke Company—

This company, of Uniontown, has awarded a contract for the construction of a coking plant of 75 ovens at the Simpson shaft recently completed. It is the intention of the company to have them completed and in operation as early as practicable. W. H. Wilkey, of Uniontown, will erect the ovens.

Oliver & Snyder—The Oliver & Snyder Steel Company has adopted the new mine roof support recently patented by Fred. C. Keighley, general superintendent of the company's three coking works near Uniontown. The installation of this support has been begun in the mine at Oliver No. 2. Thirty sets, covering a distance of 100 ft. are being put in as a beginning. Mr. Keighley states that the old roof supports will be replaced with the new kind as rapidly as they require replacement and the entire workings of the company will eventually use this equipment.

Kennerly Coal Company—Negotiations are in progress for the sale of this company's coal lands to persons understood to represent the United Coal Company, of Pittsburgh. The Kennerly company has its headquarters at Johnstown; it owns about 4000 acres of land in the Bens Creek valley in Somerset county.

United Coal Company—An explosion in the Merchants' mine of this company at Boswell, Somerset county, on Jan. 26, killed five men, including Superintendent J. G. Logan, and injured several others.

South Dakota

LAWRENCE COUNTY

Custer Peak—The company is preparing to sink another 100 ft. Superintendent O'Brien reports that the copper showing is now 3 per cent. at the 200-ft. level, the width of the ledge being 85 ft. A five-stamp gold mill will also be erected.

Hercules—Grading for the 200-ton mill has commenced and the orebody is being prepared by Superintendent Englehardt for a steady ore supply.

Homestake—The company is preparing to install a new cage to operate between the 1200-ft. and 1750-ft. levels.

Taco Bears—Work will be recommenced when the weather permits. E. H. Harriman of New York, is one of the principal owners of this property.

CUSTER COUNTY

Saginaw—Free gold was encountered by Manager Herber, of Custer, in the shaft at a depth of 34 ft. at the face of the incline. The vein will be followed up.

Texas —

JACK COUNTY

Lost Valley Coal Company—This company has begun work on the development

of its coal lands near Jacksboro, and has let contracts for the necessary machinery. J. J. Jermy, of Scranton, Penn., is in charge of the work.

Utah

BEAVER COUNTY

Utah Gold and Copper Mines Company—The fissure cut by the main tunnel a short time ago has been drifted on for 60 ft., and from 2 to 4 ft. of lead-silver ore of stoping grade has been found.

Houcrine Extension—A drift at this mine has been driven in ore for 42 ft., and ore still shows in the face. Considerable trouble has been caused by water, but a small electric pump is to be installed.

Peacock Consolidated Copper Company—At this property adjoining the King David group a drift has been run west of one of the fissures disclosed in the crosscut; this drift has cut a crossvein, the ore in which carries about 45 per cent. lead, some gold and considerable silver. In this district the ore makes at intervals in large caves in the limestone; the management feels confident that a large body of rich ore will soon be found.

SALT LAKE COUNTY

Rainbow Mining Company—The tunnel has cut a body of molybdenum ore about 250 ft. below the surface. The surface ore on this vein averaged 17 per cent. molybdenum.

Big Mitt—In this property between Big and Little Cottonwood cañons a vein, 8 in. wide and assaying high in gold and copper, has been opened up.

Ohio Copper Company—The stock of this company has been listed upon the Salt Lake exchange. The capitalization is 1,500,000 shares having a par value of \$10. The treasury contains 380,650 shares and \$76,452 in cash. The bonds outstanding amount to \$877,000. The company owns 15 patented claims at Bingham, in which 1385 ft. of shaft has been sunk and 10,782 ft. of other underground work has been done. The ore in sight is estimated at 7,000,000 tons, while the possible ore between the Mascotte tunnel and the 500-ft. level is 6,400,000 tons. The average value of the orebody on the upper levels is said to be 1.66 per cent. copper. The 2400-ton concentrating plant will soon be completed. In the lower tunnel vein, which has a depth of approximately 2000 ft., ore averaging 1.75 per cent. copper has been found. Up to date this is the best average grade that has been found in the property. The management believes that it is approaching the main orebody, and expects to find in it a higher grade of ore than it did nearer the surface.

Bingham Amalgamated Company—A deal is said to be in progress by which this company disposes of 330,000 shares

of treasury stock at about 40c. per share. While it is uncertain who is after this stock, the Utah Copper Company and the Ohio Copper Company, both of which are neighbors, have been mentioned. The Bingham Amalgamated adjoins some of the largest Bingham properties, and has a good showing.

SUMMIT COUNTY

Little Bell—On the 300-ft. level two veins are being drifted upon; it is expected that when the contact is reached high-grade bodies will be found.

Wisconsin

ZINC-LEAD DISTRICT

Beloit-Elmo—This company is rebuilding the 75-ton mill moved from the Hazel Patch, at Mineral Point.

Cuba City—A big increase in shipments will be made from this camp within the next few weeks. The Baxter, Board of Trade, Best, Henrietta, Meekers Grove and Dall are producing again. The Dall is now prepared to double its former daily production of 25 tons of concentrates; the new shaft has been connected up with 1000 ft. of tramway and a new power equipment installed. The company has just declared its fifth regular monthly dividend of 5 per cent. on \$60,000 capitalization.

Raisbeck—Milwaukee parties, represented by P. R. Grey, are unwatering the old Raisbeck mine, under option to buy.

West Virginia

MONONGALIA COUNTY

D. R. Davidson Coal and Coke Company—This company has bought 300 acres of coal land near Morgantown, and has begun work opening a coal mine. Preparations are also being made to erect a number of coke ovens. The company is controlled by D. R. Davidson and others, of Beaver Falls, Penn., owners of the Union Drawn Steel Company.

Canada

BRITISH COLUMBIA

Weather conditions during the early part of January were so severe that for several days there was a practical suspension of mining and smelting operations in West Kootenay and Boundary districts, consequent chiefly upon much ice in Kootenay river having prevented the operation of the hydro-electric power plant at Bonington falls. The difficulty was overcome by the middle of the month and work was at once resumed at the larger mines in Rossland, Phoenix and Greenwood camps, and at the several smelters treating ores from them.

BRITISH COLUMBIA—CROW'S NEST PASS

Crow's Nest Pass Coal Company, Ltd.—A new entry is being opened to one of the larger coal mines at this company's Coal Creek Colliery, that in use for 10 to 12 years having become unsafe. Operations have been resumed at the company's Carbonado colliery with about 150 men employed.

BRITISH COLUMBIA—BOUNDARY DISTRICT

British Columbia Copper Company, Ltd.—In addition to operating several producing mines and a smelter, this company is developing a new property, in Wellington camp, with encouraging results, a promising orebody having been opened on it recently.

Consolidated Mining and Smelting Company, Ltd.—Besides regularly maintaining ore production at the Snowshoe mine, in Phoenix camp, this company is developing a neighboring group of claims, known as the Phoenix Amalgamated, on which a large body of ore of shipping grade has been proved to occur.

BRITISH COLUMBIA—NELSON MINING DIVISION

Ymir Mines, Ltd.—This company is prospecting with a diamond drill in the Ymir mine.

Sheep Creek—Several mines are producing lode gold in this camp—the Queen with a 20-stamp mill, and the Kootenay Belle and Nugget each with a smaller mill. While production is not yet large it is increasing.

BRITISH COLUMBIA—SLOCAN

Whitewater—A contract for driving a 1500-ft. crosscut tunnel has been let by the Deep Mines, Ltd., the operations of which are being directed by J. L. Retalack, of Kaslo. The purpose of this work is to explore the vein at the extreme depth at which development by means of tunneling is practicable. During 1908 about 8500 tons of hand-sorted lead ore, 12,500 tons of lead concentrates, and 8000 tons of zinc concentrates were shipped from the associated Whitewater and Whitewater Deep mines.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ending Jan. 16 were as follows: Crown Reserve, 120,000 lb.; La Rose 336,800; McKinley-Darragh, 61,560; Nova Scotia, 360,000; Nipissing, 85,262; O'Brien, 63,830; Trethewey, 60,000; total 1,087,552 pounds.

Badger—A new plant is being installed comprising two 100-h.p. boilers and a 10-drill compressor, with dynamo for electric lighting, hoists, etc., which will be in operation about the middle of February, when development will be undertaken on a large scale. The main shaft is down 223

ft. with about 300 ft. of drifting on the 100- and 200-ft. levels, on a vein yielding high-grade ore. No. 5 shaft is down 160 ft. with 150 ft. of drifting at the 150-ft. level, on a vein which so far is low in silver. It will be tested at depth by a diamond drill.

Columbus—The main shaft is down 250 ft., where a station is being cut, and development will be carried on extensively at this level. A crosscut will be run to cut No. 2 vein lying about 68 ft. east, and at this point diamond drilling will be undertaken to cut a big vein at a depth of 300 feet.

Foster—Drifting is being done on a vein running under Glen lake, which is between 2 and 3 in. wide and is yielding good ore.

La Rose—A body of high-grade ore has been added to the reserves of this company. So far nearly all the ore shipped has been taken from or above the 110-ft. level. A good deal of development work has been accomplished at the 200-ft. level, but little ore has been taken out. In running a winze to connect the two levels recently the main vein was encountered showing an average width of 11 in. and carrying about 4000 oz. to the ton. This increases the depth of the ore reserves by 90 feet.

Trethewey—The report for the annual shareholders' meeting to be held Jan. 27, covering the period of 16 months ending Dec. 30 shows a total revenue of \$357,970, with an expenditure of \$147,446, leaving profits of \$210,524. Of this amount dividends at 15 per cent., or \$141,817, have been paid, leaving a balance of \$68,706 at the credit of the revenue account. This with the balance carried forward from the previous year gives a balance of \$113,108.

ONTARIO—MONTREAL RIVER DISTRICT

Ottiss-Carrie—This is the first of the Montreal River mines to make shipments of ore. It is now hauling high-grade ore to Charlton where an ore and freight shed is being built for the company beside the railway track. A carload will shortly be sent to the smelter.

Mexico

CHIHUAHUA

Palmilla—This mine in the Parral camp, operated under bond and lease by Shepherd & McQuatters, is now producing at the rate of about 35 tons daily. Excellent progress is made in the driving of the transportation-drainage tunnel.

La Reina de Plata—Another pocket of high-grade lead-silver ore was lately opened up at this Santa Eulalia mine, of which Capt. Lindsay Brown is manager; 30-oz. silver ore is shipped.

Greene Concession—While no official announcement has been posted regarding the termination of the immense mineral

rights to lands in Chihuahua and Sonora, and in spite of the fact that the Minister de Fomento has recently refused to grant locations made within the tract, it is nevertheless believed that neither Col. W. C. Greene nor his authorized representatives have taken the required steps toward the postponement of the expiration date, Jan. 12. It is likely that definite announcement of some sort will shortly come from government officials at Mexico City. Recent reports are to the effect that W. C. Greene's mineral concession, embracing large areas in the districts of Guerrero and Rayon of this State and in the Sahurita district of Sonora, expired on Jan. 12. In any event it is not known that either Colonel Greene or his representatives have made any decided move toward its extension. If this is correct it is probable that many denouncements will be shortly recorded and that work will begin immediately in a number of places.

Batopilas—A recent shipment of bullion from this old mine consisted of 199 bars valued at 102,000 pesos.

Roncesvalles—E. F. Armstrong and London associates have lately resumed developments at the Pinos Altos property.

Parral Output—The Parral camp produced for the week ending Jan. 14 a total of 8820 tons, of which 5840 tons were locally milled and the balance sent to out-of-the-district smelters.

Rio Tinto Copper Company—This company started up its new 300-ton copper smelter at Terrazas on Jan. 15. The company's mines furnish the bulk of the ores, but some custom tonnage is received.

Fortuna—This property in the Calabacillas gold section accessible from the Mexican Central railway, is under bond to G. B. Jacobs and associates, who are doing development work.

Chihuahua Copper Mining Company—This company operating in the Chorreros mountains east of Chihuahua has temporarily suspended milling operations on account of water difficulties in the mine. The manager, Ross D. McCausland, is now in the United States for the purpose of purchasing more power and pumping machinery.

Los Angeles—This property in the Minas de Oro section of the Guadalupe y Calvo district is being operated by Stallforth Brothers, of Parral. The mill is running on a good grade of ore.

Santa Rosalia Smelter—The long-built smelting plant of the Encinillas company was blown in about a month ago, and is reported in satisfactory commission. Custom ores are received, although the company is operating several mines of its own which supply a large tonnage. J. L. Saint-Dizier is the general manager.

COAHUILA

Torreón Smelting Works—Reports from Boston state positively that this plant has been bought by the new International Smelting Company, the recently formed competitor of the American Smelting and Refining Company.

DURANGO

La Libertad—It is reported that this old mine in the San Diego district is to be reopened. The mine is opened by an adit more than 1000 ft. long. The ore will be shipped to Torreón.

GUANAJUATO

Shipments—The value of the ore and bullion shipped from the Guanajuato district during the week ending Jan. 18 amounted to \$254,800. Of this total bullion sent chiefly to Mexico with a small amount to New York made up \$167,500, the remainder being ores and concentrates.

San Cayetano—The work of unwatering the old workings is progressing rapidly. The drift is now near the point where the several million tons of water will be tapped. The work will also drain two other mines.

Mariquita—This silver mine in the Zacualpan district, which has been closed for the last few months, is to resume operations with two shifts.

MICHOACAN

Dos Estrellas—This company has declared a dividend of \$1 per share, representing a disbursement of \$300,000.

SONORA

Greene-Canaña—According to a preliminary report, Dec. 31, 1908, the production in 1908 was 19,128,000 lb. copper; average price 13.745c.; gross receipts, \$2,622,143; estimated cost, 10½c. per lb. In addition to the copper there was produced 449,246 oz. silver, and 3046 oz. gold. The Capote mine is yielding 250 to 300 tons of ore per day; the Oversight, 800 tons. Since the smelter resumed operations in July, the copper recovery has been 47 to 50 lb. per ton of ore.

New Caledonia

Exports of minerals from New Caledonia for October and the 10 months ended Oct. 31 are reported by the *Bulletin du Commerce*, of Noumea, as follows, in metric tons:

	October.	Ten Mos.
Nickel ore.....	12,680	109,239
Cobalt ore.....	263	3,286
Copper ore.....	11	10
Iron ore.....	11	44
Chrome ore.....	3,052	40,237

Exports of metals for the 10 months included 5 tons of lead and 5150 kg. silver.

The boring for petroleum at Anse-Vata, near Mount Owen-Toro, has reached a depth of 125 meters. At this depth there are strong indications of the existence of oil.

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, Jan. 27.—The coal trade in the West has been rather disappointing. In steam coal, progress is still exceedingly slow, and from some consuming centers a falling off is reported this week instead of an advance. The weather over the greater part of the West continues mild and the demand for domestic coal has been comparatively light. The coal operators are attributing the slow trade in steam coals to all sorts of causes, but no two of them agree except in the fact that business is dull. Most mines are running on short time. Prices at the principal markets have not suffered as much as might be expected, since shipments have been kept down, and at Chicago, Cleveland and other leading points there is very little demurrage coal forced for sale.

The Seaboard bituminous trade is quiet and sales are reported light. Business in the interior cities in the East is rather better than on the Seaboard, but there is not much to boast about.

Anthracite trade is dull and shipments from the mines to consumers are slow. A good deal of coal is still being stored to provide against contingencies.

It is understood that at a recent meeting of representatives of the larger coal companies in the Pittsburgh district, it was decided to appeal to the Interstate Commerce Commission with regard to the rates on coal to Lake Erie ports. It is claimed that, the relative distances being considered, the present rates discriminate against Pittsburgh shipments and in favor of West Virginia and Ohio coals.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to Jan. 18, 1908, and Jan. 16, 1909, in short tons:

	1908.	1909.	Changes.
Anthracite.....	247,484	182,974	D. 64,510
Bituminous.....	1,704,452	1,462,326	D. 242,126
Coke.....	325,385	441,833	I. 116,448
Total.....	2,277,321	2,087,133	D. 190,188

Average daily tonnage, 126,518 in 1908, and 130,446 in 1909; increase, 3928 tons.

The anthracite-coal shipments, by regions, or districts, for the full year were, in long tons:

	1907. Tons. Per Ct.	1908. Tons. Per Ct.
Schuykill.....	20,141,288 30.0	18,006,468 27.9
Lehigh.....	8,929,869 12.4	7,780,285 12.0
Wyoming.....	38,638,146 57.6	38,872,291 60.1
Total.....	67,709,393 100.0	64,665,014 100.0

Allowing the usual percentage for coal

used and sold at mines, the production of anthracite in 1908 was approximately 73,720,000 long tons, equivalent to 82,566,400 short tons.

Coal report of Monongahela River Consolidated Company, fiscal year ended Oct. 31:

	1907.	1908.	Changes.
Pittsburg district.....	7,321,961	5,985,486	D. 1,336,475
Kentucky.....	132,196	110,624	D. 21,572
Total mined.....	7,454,157	6,096,110	D. 1,358,047
Coal sold.....	8,389,114	6,044,307	D. 2,294,807

Decrease in coal mined, 18.2 per cent.; in coal sold and delivered, 27.5 per cent.

Coal receipts at Boston, year ended Dec. 31, reported by Chamber of Commerce:

	1907.	1908.	Changes.
Anthracite.....	2,053,328	1,776,401	D. 276,927
Bituminous.....	3,184,964	3,302,929	I. 117,965
Total domestic.....	5,238,292	5,079,330	D. 158,962
Foreign.....	545,652	370,709	D. 174,943
Total.....	5,783,944	5,450,039	D. 333,905

The foreign coal reported is chiefly from Nova Scotia, though some comes from Great Britain.

Coal passed through the locks on the Monongahela river above Pittsburgh for the year was 10,743,317 short tons in 1907, and 8,563,909 in 1908; a decrease of 2,179,408 tons, or 20.3 per cent. The decrease was largely due to the long period of low water, which prevented shipments of coal down the Ohio.

New York

ANTHRACITE

Jan. 27.—The hard-coal market continues quiet. It is still mainly a weather market, with all sizes in good supply. Several of the large companies are running only part time this week, some of them three and some four days. From present appearances this will continue to be the rule for some time.

Prices are unchanged. The list prices for prepared sizes are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points.

BITUMINOUS

Business in soft coal is very slack. What little is doing goes by fits and starts. Orders coming in for a day or two and then being entirely absent for several days at a time. This applies to the far East, to the Sound and to New York harbor. At the same time there is no pressure to sell coal, as most of the com-

panies are shipping only on orders and there is little stock at tidewater.

All-rail trade is a little better than the tidewater business. There is a general feeling that consumers' stocks must be extremely low and that pretty soon they will have to put in more coal.

In New York harbor good grades of steam coal can be bought at \$2.40@2.50 and gas coal at \$2.25 for run-of-mine. A little incident of the week has been a demand for gas slack, which is selling at 65@70c. at mine, or higher than run-of-mine. This is due to the fact that sales of screened coal have been small, and in consequence production of slack has been cut down until it is below the demand.

Cars are abundant but transportation is rather slow, coal taking nine or 10 days to come through.

In the Coastwise trade there is little doing. Vessel owners appear to have fixed a minimum at 75c. from Philadelphia to all points beyond Cape Cod, and no boats are offering below that price.

Birmingham

Jan. 25.—Coal producers in this State report the trade quiet. There is, however, a heavier output at the mines than has been noted for some time in the past. The shipment of coal into the Louisiana market has been stopped, the receipt of a large tonnage of coal from Pennsylvania down the river there affecting this territory. Coke making is being held up to its top notch, there being a good demand on all sides. The accumulated stock is being kept up, and any improvement in iron making will be met easily.

Chicago

Jan. 25.—Mild weather again over Chicago territory has weakened the demand for coal generally and especially for domestic supplies. The consequence has been considerable selling of Illinois lump at discounts of 10@25c. from the current market prices and a weakening of the market for anthracite, free coal becoming more in evidence and having a better chance of sales. Smokeless continues in large supply and high-grade smokeless has suffered from extensive advertising of a large purchase by a leading firm in city trade. The market is now closely responsive to weather conditions and will continue to be dull unless supplies are greatly restricted or much colder weather comes.

Illinois and Indiana coal brings \$1.85@2.65 for lump and egg, \$1.60@1.75 for run-of-mine, and \$1.30@1.60 for screenings. Smokeless run-of-mine has brought in some cases 86¢/cwt. at mines, or \$2.85@2.95 Chicago, although Pocahontas and New River have sold up to \$3.15. Hocking Valley has fallen off in sales with the mild weather and is sluggish at \$3. Youghiogheny is quiet at \$3.15 for 34-inch and Pittsburg No. 8 is dull at \$2.65@2.75. Anthracite has become in light demand again with the weather and shows little prospect of activity until freezing temperatures return.

Indianapolis

Jan. 26—The disturbing factors in business are still apparent, and the demand for steam coal is small. The operators, however, are not discouraged, but remain hopeful that disturbing factors will soon be settled.

There is a report that the Frick Coke Company will build ovens on a tract of 200 acres of land at Indiana harbor on lake Michigan, not far from the plant of the Indiana Steel Company at Gary.

Pittsburg

Jan. 26—The rivers were navigable all week and fully 6,000,000 bu. of coal were shipped to lower ports. A large proportion was loaded in coal boats which hold 25,000 bu. each and went to the New Orleans market. A number of empty coal boats and barges returned on the rise, and all the river mines are in full operation. Conditions in the rail trade are not so encouraging, and this week it is estimated less than 25 per cent. of the railroad mines are running. The large operators are adhering strictly to the old prices, based on \$1.15 per ton for mine-run coal at mine; slack is held firmly at around 75¢. Some small independent interests are cutting these prices, and it is possible to buy a limited tonnage on the basis of \$1 per ton for mine-run coal.

Connellsville Coke—The coke trade continues in bad shape, and sales of prompt coke are still being made at low prices. The large producers, however, have entered into an agreement not to sell furnace coke at less than \$1.75 for spot shipment and on contract at \$1.90@2. This is a concession from the quotations made in December and indicates that many blast furnaces are still on the idle list. Conditions in foundry coke are better than in furnace, the lowest spot price named so far being \$2.15 and on contract \$2.25@2.40. The Courier gives the production in both regions at 262,440 tons. The shipments amounted to 9118 cars as follows: To the Pittsburg district, 3306; to points west of Pittsburg, 5155; to points east of Connellsville, 657 cars.

Foreign Coal Trade

British Coal Exports—Fuel exports from Great Britain, with coal sent abroad for use of steamships in foreign trade, year ended Dec. 31, long tons:

	1907.	1908.	Changes.
Coal.....	63,000,947	62,547,175	D. 1,653,772
Coke.....	981,414	1,195,096	I. 213,682
Briquets.....	1,480,893	1,440,438	D. 40,455
Total exports...	65,063,254	65,180,649	D. 882,690
Steamer coal.....	18,618,828	19,474,174	I. 855,346
Total.....	84,682,086	84,654,823	D. 27,263

The larger exports in 1908 were 40,415-430 tons to France, 9,640,868 to Germany, 8,742,634 to Italy and 4,370,468 tons to Sweden.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on Jan. 15: Best Welsh steam, \$3.48; second, \$3.36; thirds, \$3.24; dry coals, \$3.60; best Monmouthshire, \$3.18; seconds, \$3.06; best small steam, \$2.04; seconds, \$1.74. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, Jan. 27—The iron and steel trades remain quiet and generally in a waiting position. While the tariff discussion may have some effect, this condition of affairs seems to be due rather to uncertainty as to what extent consumers of finished material may be ready to absorb it for final use.

In pig iron the bulk of the business at consuming and distributing centers is still in small quantities. Foundry pig is moving to some extent, but apparently only as melters need it to fill orders already obtained. The busiest consumers of foundry iron seem to be the cast-iron pipe makers who are contracting more freely than any one else.

In finished material the outlook is about the same, except in plates and structural material. The New York Central has ordered 2000 steel cars and the Pennsylvania railroad is understood to be figuring on 3000. These orders will require a good deal of material. Quite a number of building contracts are being taken by the fabricating companies in the East and in Chicago. They are chiefly for buildings of moderate size but make up a considerable total. It is to be noted that nearly all of the material will be furnished by the independent companies which are cutting prices considerably. It is stated that the Steel Corporation is adhering strictly to its schedule rates, but the actual business placed is going at lower prices.

Rail orders are still light from the railroads. There is a considerable business doing in light rails which are, however, generally ordered in small quantities.

A condensed summary of the Steel Corporation report for the December quarter is given elsewhere.

Virginia Pig Iron Association—This association has been formed by owners of

Virginia blast furnaces to confer with regard to sale and production of iron. The officers are: President, E. C. Means, Low Moor Iron Company, Low Moor, Va.; secretary, H. L. Haldeman, Pulaski Iron Company.

Baltimore

Jan. 25—Exports for the week included 475,054 lb. tin scrap to Rotterdam; 87,835 lb. spelter and 2,455,800 lb. steel billets to Liverpool.

Birmingham

Jan. 25—Quiet but firm is the way the Southern pig-iron manufacturers put it when asked as to the condition of the market. The sales are about equal to the make and the furnaces in blast are holding up the pace that was set some time back. There appears to be no apprehension in this section, and conditions are being accepted. There is complaint at the agitation on a change in the tariff on iron and steel, the manufacturers in this section being of the opinion that any reduction would play havoc with this district more than elsewhere.

The quotations for Southern pig iron continue on a \$13 per ton, No. 2 foundry basis. The make in this territory can be increased just when needed. All demands for iron can be met right along. The sale of the 20,000 tons of iron, delivery during the first half of the year, by the Sloss-Sheffield Steel and Iron Company to one of the leading cast-iron pipe concerns is confirmed. The reported sale of the Dimmick cast-iron pipe plant in this district to the Alabama Consolidated Coal and Iron Company has not yet been consummated. The negotiations have been on for some time. The steel plant at Ensley is in full operation in every department and there is a steady production.

Chicago

Jan. 25—The iron market continues quiet, although inquiries for pig iron are increasing. Present requirements of melters continue small and there is no disposition to venture much into the future. Purchases run from a carload to 500 tons, with an occasional lot up to 1000 tons. For future delivery inquiries range small, few exceeding 1000 tons. Sales now are confined to the needs of the next three months almost entirely.

Prices hold firm on such business as is being done, at \$13 Birmingham (\$17.35 Chicago) for Southern No. 2 and \$17.50 for Northern No. 2. Any considerable transaction would doubtless obtain lower prices. Production of Northern iron is held down closely to prospective requirements, and this seems likely to assure stability of Northern prices locally.

Sales of iron and steel products are not

large, but the market seems firm. In railroad supplies there is a little life, but signs do not point to any heavy business. Coke is selling well, but Connellsville is a trifle lower in price, owing to large shipments, being now \$4.75@4.90 Chicago.

Philadelphia

Jan. 27—Consumers of pig iron are exhibiting more indifference to iron than for months. Certain rumors have reached this market concerning possible reductions which may make it worth while for buyers to hold off. One or two well known brands are selling—or rather are offered—at 50c. less than heretofore, but other makers have not followed suit. That crude iron will yet find a lower level is an opinion which prevails among large buyers. There is no buying movement in sight, notwithstanding large consumers are close to the end of their stock. Material for pipe iron was again shaded by two or three Virginia furnaces. Local sales are devoid of significance. Second quarter necessities will be covered very cautiously. Four or five middle and eastern Pennsylvania furnaces are to be put in blast before spring, and canvassing for business is now in progress.

Steel Billets—An average consumption of steel billets is kept up in this territory, and there has been no known departure from December quotations.

Structural Material—The local mills are not increasing output. The Steelton mills are turning out a little more material than in December. Local requirements are unimportant.

Scrap—Scrap dealers are quietly preparing for a large spring demand for heavy steel, railroad and one or two other kinds. They are now buying stock on most advantageous terms.

Pittsburg

Jan. 26—Conditions in the iron and steel trade are more discouraging than at any time since the close of last year. A decided falling off in orders is noted by the large interests with a few exceptions. The large interests refuse to make any concessions in prices and are waiting for a good spring demand. The railroads are not coming into the market for their rail requirements as early as anticipated but the Carnegie Steel Company continues to take on small tonnages for both standard sections and for light rails. The New York Central lines will take 80,000 tons of rails and the Carnegie company will roll a large proportion of this order. It also will be given the order for the Pittsburg & Lake Erie road which will amount to about 10,000 tons. It is understood these contracts will be definitely placed this week. The Baltimore & Ohio Railroad likely will come into the market in a few

days for about 100,000 tons, most of which will go to the Carnegie company. The wire trade is dull at present. The American Steel and Wire Company is operating all of its plants in the Pittsburg district at almost 80 per cent. capacity, except the Donora works which are on half time.

Pig Iron—The pig-iron market is in worse shape than it has been for probably a year. What little business is being offered is at extremely low prices. These sales cannot, however, be regarded as the market as some of them were under special conditions and others were of resale iron. Comment was made on the fact that a large casting company bought 100 tons of standard bessemer for prompt delivery at \$16, Valley furnace, and this price was duplicated by another concern yesterday for a 75-ton lot. A large engineering concern last week bought 300 tons of No. 2 foundry at \$15, at furnace. Both of these prices are 50c. a ton under what has been considered the minimum market price. Furnaces in the Valleys continue to store iron and one furnace is said to have a stock of fully 80,000 tons. The Jones & Laughlin Steel Company is operating all of its blast furnaces, although its steel plants are running at less than 50 per cent. of capacity. This company is said to have over 200,000 tons of pig iron on its yards. Pig-iron quotations for prompt and first-quarter delivery are as follows: Standard bessemer, \$16.50; malleable bessemer, \$15.75; basic, \$15.50; No. 2 foundry, \$15.50; gray forge, \$14.50, all f.o.b. Valley furnaces. These prices, however, may be shaded.

Steel—There is no new business of any consequence in crude steel and stocks are accumulating. The price remains at \$25. Pittsburg, for both open-hearth and bessemer billets with freight divided. Plates are being shaded by about \$2 a ton but the regular price remains at 1.60c. Merchant-steel bars are still quoted at 1.40 cents.

Sheets—The sheet market is fairly good as to tonnage, but much of the new business taken is at from \$16 a per ton under the regular quotations which are 2.50c. for black sheets and 3.55c. for galvanized No. 28 gauge.

Ferro-Manganese—No new business; prices continue at \$40@46.50, Pittsburg.

Foreign Iron Trade

Belgian Iron Production—Pig iron made in Belgium in the 10 months ended Oct. 31 was 1,185,270 metric tons in 1907, and 985,570 in 1908; a decrease of 199,700 tons, or 16.9 per cent.

Iron and Steel in Italy—Official returns give the production of iron ore in Italy, chiefly from Elba, at 518,000 tons in 1907. In that year there were eight blast furnaces in operation, which made 112,000 tons of pig iron. A large quantity of pig

is imported for conversion into steel. The wrought iron made was 248,000 tons, and the steel ingots 347,000 tons. The steel was made in two converters and 42 open-hearth furnaces.

British Iron Trade—Values of exports and imports in Great Britain, 12 months ended Dec. 31, as given by Board of Trade returns:

	Exports.	Imports.	Excess.
Iron and steel	\$37,328,413	£ 7,679,655	Exp. £29,648,758
Machinery	31,018,912	4,556,702	Ex. 26,462,150
New ships	10,566,990		Ex. 10,566,990
Total	£78,914,315	£12,236,417	Ex. £66,677,899
Total, 1907	88,324,752	12,928,858	Ex. 75,395,894

Decrease in exports in 1908 was £3,410,437, or 10.6 per cent.; decrease in imports, £292,441, or 2.3 per cent. The quantities of iron and steel were, in long tons:

	1907.	1908.	Changes.
Exports	5,132,227	4,109,976	D. 1,021,251
Imports	935,472	1,119,924	I. 183,552

The imports in 1908 were largely of blooms, billets and other half-finished material.

Metal Market

New York, Jan. 27—The metal markets have continued quiet during the week, with few changes but some important developments in copper and spelter.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

	Total.	Exports.	Imports.	Excess.
Gold:				
Dec. 1908..	\$ 7,358,707		\$ 5,122,538	Exp. \$2,236,169
1907..	1,094,441		44,448,515	Imp. 43,444,074
Jan. 1908..	71,235,456		50,246,009	Exp. 20,989,357
" 1907..	55,215,681		143,398,072	Imp. 88,182,391
Silver:

" 1907..	4,413,698		4,222,036	" 191,662
Jan. 1908..	51,837,671		42,186,366	" 9,651,305
" 1907..	61,625,866		45,912,360	" 15,713,506

Exports from the port of New York, week ended Jan. 23: Gold, \$763,125, principally to Buenos Aires; silver, \$974,780, chiefly to London. Imports: \$120,680, from the West Indies, South America and Australia; silver, \$68,104, from Mexico and Central America.

Gold and silver movement in France, 11 months ended Nov. 30:

	Imports.	Exports.	Excess.
Gold	Fr. 885,908,000	F. 22,464,000	Imp. Fr. 863,504,000
1907..	416,334,000	142,468,000	Exp. 273,876,000
Silver	156,509,000	199,465,000	Imp. 43,956,000
1907..	161,723,000	191,436,000	Exp. 29,713,000

Imports of copper and nickel coins, 95,000 fr. in 1907, and 68,000 fr. in 1908; exports, 681,000 fr. and 731,000 fr., respectively.

Coinage of the Royal Mint of Great Britain for the full year:

	Imperial.	Colonial.	Total.
gold	15,725,998		15,725,998
Silver	23,804,187	9,510,829	33,315,016
Brass	52,301,808	99,900	52,401,808
Nickel		12,817,152	12,817,152
Aluminum		12,134,968	12,134,968
Total	91,921,993	34,561,613	126,483,602
Total, 1907	128,606,038	31,972,134	160,578,172

The total value of gold coined in 1908 was £14,600,000; light and defective coins

withdrawn, £3,300,000; leaving £11,300,000 net increase of coinage.

Gold and silver movement in Great Britain, year ended Dec. 31:

	Imports.	Exports.	Excess.
Gold, 1907.....	£46,145,314	£49,909,069	Exp. £3,823,785
Gold, 1907.....	57,088,547	50,806,009	Imp. 6,222,538
Silver, 1907.....	40,826,869	13,263,888	Exp. 2,956,999
Silver, 1907.....	16,293,892	16,920,849	Exp. 936,957

Of the silver imported in 1908 a total value of £8,305,976 is credited to the United States. In 1908 the gold exports exceeded the imports, a very unusual condition.

Gold—The price of gold in the open market in London is lower this week, bars being quoted at 77s. 9½d. and American eagles at 76s. 4¼d. per ounce. The Bank of France has stopped taking gold for the present, and nearly all the gold arriving from South Africa and Australia this week was taken by the Bank of England. There have been no further exports from New York to Argentina on London account.

Platinum—The market continues quiet, dealers reporting prices unchanged at \$23.50@24.50 per ounce for refined platinum; \$26.50 for hard and \$19@21 for scrap. The market is rather easy.

Our St. Petersburg correspondent writes under date of Jan. 14, that 'a little depression is to be noted in the market at Ekaterinburg; the small miners and brokers there are offering crude platinum—83 per cent. pure metal—at 5 rubles per zolotnik, equal to about \$18.80 per ounce. In St. Petersburg the market was dull on account of the holidays, but some small sales of crude metal were made at 20,500 rubles per pood, equal to about \$20.50 per ounce.

Silver—The silver market has fluctuated this week between 23 11/16 and 24 1/8d., being influenced by speculative operations in India and China. The market closed steady at 51¾c. in New York.

SILVER AND STERLING EXCHANGE

Jan.	21	22	23	25	26	27
New York....	51½	51½	51½	52	52½	51½

26	14 1/4 @ 14 1/2	13 1/2 @ 13 3/4	59 1/2	27 1/2 @ 28	4.15 @ 4.17 1/2	5.10 @ 5.15
27	14 1/4 @ 14 1/2	13 1/2 @ 13 3/4	59 1/2	27 1/2 @ 28	4.15 @ 4.17 1/2	5.10 @ 5.15

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York cash. The price of electrolytic is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—The London market, which, in a measure, has been the key to the situation, has again declined, inducing sellers to make further concessions, which early in the week resulted in a fairly active business, at least insofar as electrolytic is concerned. The supply of Lake that is offered being so much less than electrolytic, buyers of it have had to meet the demands of the sellers. This accounts for the increased disparity between the prices for the two grades. Both in Lake and electrolytic the business has been done chiefly for domestic account, European buyers having been conspicuous by their absence. This is, of course, to be explained by the continuance of the price for Standard in London below the New York parity. European manufacturers have, therefore, been able to supply their requirements by buying copper out of warehouse in London, which they can do at a lower price than for shipment from this side. As we have previously pointed out, it would be possible here to re-import American cathodes, but that has not been done and probably will not be attempted. However, the sale from warehouse abroad comes practically to the same thing, inasmuch as depletion of stock there is offset by a corresponding increase here. Since Jan. 25 the activity in this market, above noted, has subsided, due to rumors, which have found wide publication, of the contemplation of a sweeping cut in the price of electrolytic copper. The market closes weak at 14@14½c. for Lake copper; 13½@13¾c. for electrolytic in ingots, cakes and wirebars. The average of the price for casting copper is 13¼@13½c. cents.

Copper sheets, cold-rolled, 20c.; hot-rolled, 19c. per lb., base. Copper wire, 15¾c. base, carload lots at mill.

The Standard market has declined about 1¢ during the week. Though the

close is at the lowest, a little more steadiness is shown, the quotations being cabled at £59 5s. for spot, £60 2s. 6d. for three months.

Refined and manufactured sorts we quote: English tough, £64; best selected, £63@64; strong sheets, £75@76.

Exports from New York and Philadelphia for the week are reported at 4787 long tons copper. Our special correspondent gives the exports from Baltimore at £1468 long tons.

Tin—There was no special feature to the London market, which ruled fairly steady throughout the week, the transactions in both spot and futures being of small proportions. The close is cabled at £125 15s. for spot, £127 10s. for three months.

The domestic market still suffers from an entire lack of interest on the part of both consumers and dealers. The latter anticipate a lower market on account of the unfavorable statistical position of the metal, and are willing to wait for a decline before again taking an active interest in the metal. Tin can be purchased at the close at about 27½ cents.

The Goldschmidt Detinning Company has been organized in New York with \$3,000,000 capital, to recover tin from scrap by the chlorine process devised by Dr. Karl Goldschmidt. This process is in successful use at Essen-Ruhr, Germany, and Lyons, France. The president of the new company is William T. Graham, who is also president of the American Can Company. It is understood that the Goldschmidt company has contracted to take all the American Can scrap.

Lead—Business is of small volume and the quantities put on the market by Western sellers can only be disposed of with difficulty. The market closes weak at 4.15@4.17½c. New York.

The London market is unchanged at £13 2s. 6d. for Spanish lead, £13 5s. for English lead.

Spelter—Consumers appear to be well supplied for the time being, and though the quantities offered are not large, there is no ready market, and sales can only be effected by offering concessions. The market closes lower at 4.92½@4.97½c. St. Louis, 5.07½@5.12½c. New York.

The London market is firmer and quotations close higher at £21 12s. 6d. for good ordinaries, £21 17s. 6d. for specials.

It was reported on Jan. 25 that the American Zinc, Lead and Smelting Company has decided to close down 50 per cent. of its smelting capacity, both at Caney and at Deering. This will make a curtailment of 20,000 tons of spelter per annum and will reduce this company's shipment of ore from the Joplin district by about 850 tons per week. This action is inspired by the high price for zinc ore and the relatively low price for spelter.

Base price of sheet zinc is 7c. f.o.b. La Salle-Peru, Ill., less 8 per cent

Other Metals

Antimony—The market has been dull during the week, with few sales. Quotations are unchanged, 8½¢@8¼¢, being asked for Cookson's, 8@8¼¢, for Hall-t's, and 7½¢@7½¢, for ordinary brands.

Aluminum—There has been no change during the week. The Aluminum Company of America still quotes 24c. per lb. base for No. 1 ingots; 33¢@34c. base for sheets. Foreign metal is offered at 21½¢@23c. for ingots.

Quicksilver—New York quotations are unchanged at \$45@46 per flask of 75 lb. San Francisco prices are \$45@46 for domestic orders, and \$43@44 for export. The London quotation is £8 7s. 6d. per flask, with £8 6s. 3d. named by jobbers. Business is quiet.

Nickel—Large lots, contract business, 40¢@45c. per lb. Retail, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. These quotations are for spot nickel. The price for electrolytic is 5c. higher.

Cadmium—In 100-lb. lots, 75c. per lb., at Cleveland, Ohio.

Magnesium—This metal is offered in New York at \$1.25 per lb. in 100-lb. lots. The price is \$1.40 per lb. for 5-lb. lots.

Zinc and Lead Ore Markets

Platteville, Wis., Jan. 23—The highest price paid for zinc ore this week was \$43.50; the base price was \$42 to \$43 per ton of 60 per cent. zinc. For 80 per cent. lead ore \$50 per ton was paid.

SHIPMENTS, WEEK ENDED JAN. 23				
Camps.	Zinc ore, lb.	Lead ore, lb.	Sulphur ore, lb.	
Highland.....	241,800			
Cuba City.....	232,950			
Strawbridge.....	204,100			
Platteville.....	203,080			
Daysiding.....	172,000			
Hazel Green.....	168,400			
Galena.....	80,000			
Livingsh.....	80,000			
Rewey.....	56,650			
Total.....	1,437,140		219,500	
Year to Jan. 23.....	8,816,616	60,000	772,400	

Highland, Linden and Mineral Point are not reported. Hazel Green shipped last week, not then reported, 405,480 lb. zinc ore.

In addition to the above there was shipped this week to the American Zinc Ore Separating Company, formerly known as the Platteville Separating Company, 258,360 lb., and to the Joplin Separator Works 149,000 lb. zinc ore

The district will suffer a loss in tonnage shipment by the indefinite closing of a number of producers at Highland and Benton, including properties which kept producing all through the panic; such losses, however, will be partially overcome

by increased shipments from Platteville, Rewey, Harker and Cuba City.

Joplin, Mo., Jan. 23—The highest price reported paid was \$44, the base price ranging from \$40 to \$43 per ton of 60 per cent. zinc. Zinc silicate sold on a base of \$20 @22.50, the highest being \$36.50 per ton. The average price, all grades, was \$38.68. The highest price reported paid for lead was \$54, medium grades bringing \$52 to \$53, and all grades averaging \$53 per ton.

The market opened early in the week with a few bins selling on \$43 and \$42.50 base, lowering as the week progressed to a \$42 base, and at the week-end \$40 base was the best offering. It seems to indicate that the market weakened more than will be sustained at the opening prices next week, yet the output was exceptionally heavy and this may reflect a greater weakness. The weather, following the heavy snow and blizzard of the previous week, was ideal for mining operations.

NOTE.—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

Chemicals

New York, Jan. 27—The market as a whole has shown no unusual signs of activity. Many dealers view the situation as tame and uninteresting, and buyers do not seem ready yet to do business beyond their immediate needs.

Copper Sulphate—Demand is fair and no shading is reported, there being little outside stuff on the market. Quotations are steady at \$4.75 per 100 lb. for car-load lots and up to \$5 per 100 lb. for smaller parcels.

Arsenic—The market is dull, only a few small sales of Canadian product being reported. Quotations are 3¢@3¼¢, per lb. for white arsenic.

Nitrate of Soda—Comparatively little is doing in this article. Current quotations are 2.17½¢. for spot and 2.15c. for futures, which are a shade higher.

Mining Stocks

New York, Jan. 27—At the beginning of the week the general markets were inclined to be weak, and there was some drop in quotations; Amalgamated Copper, for instance, falling off several points. The dividend of \$3 on Boston & Montana, declared last week, was an indication that there would be no change in the profit division of the Amalgamated, and that company declared the quarterly dividend of 50c. per share, which has been the rule for some time. During the last three days of the week the market was rather dull, but developed considerable firmness, and there was very little change in prices.

On the Curb the coppers followed very much the course of Amalgamated, Cumberland-Ely and Ohio were the leaders in a slight drop on Thursday and Friday, but after that most of the shares remained steady on moderate trading. Fluctuations were small. The Nevada gold stocks received considerable attention during the week, and generally held up well. Cobalt stocks were rather quiet and closed with a softer tendency.

Boston, Jan. 26—There is no rush to trade, and the market for mining shares continues uninteresting. Prices show slight losses for the week in the main, but the changes are unimportant. Outside of a few stocks the market has been extremely narrow. There has been little selling pressure. The declaration of the usual 50c. dividend by the Amalgamated company is what was expected. The stock has varied from \$77.87½ to \$79.50, closing fractionally below a week ago at \$78.50. North Butte has been weak and records a decline of over \$2. The regular \$1 quarterly dividend is expected to be declared.

Conferences have been held between the Calumet & Hecla and Osceola officials but nothing has come in the matter of a compromise. The closing down of the Arizona mines on account of labor troubles caused weakness in these stocks.

Keewenaw Copper has been taken from the Curb and put on the unlisted department of the Stock Exchange. It did not improve the price of the stock, which is off to \$4.50.

First National Copper performed stunts on the Curb, advancing to \$0.75, with reaction to \$7.62½ today. Ahmeek made a new high record at \$160, but there are only 50,000 shares. Raven Mining stockholders are given the privilege of subscribing for new shares at \$1 in the proportion of one new for 10 owned. The stock was under 90c. today.

San Francisco, Jan. 22—In the mining-share market in this city, for the first time in years, stocks of the newer Nevada mining districts have been neglected in favor of the old Comstocks. Not only is Eastern capital behind the Comstocks but the local support is better than it has been for years. The control of the Crown Point, Yellow Jacket, Belcher and other mines has changed hands and people have more confidence in the new men than in the old. Expenses have been materially reduced and the work accomplished in the past two years is being recognized.

The active listed oil companies of the California Oil and Stock Exchange paid in December, \$615,109 in dividends, which is supposed to be about half what the oil companies of the entire State paid. The total dividends paid by these oil companies to date has been \$18,008,882 which is a record to be proud of. Thirty-five of them paid dividends in December last. The petroleum interests of the State are gradually enlarging in importance and have already overshadowed those of the gold miners.

Coal, Iron and Other Industrials—United States

[illegible]

*Mexican Currency. †Since reorganization. ‡Since August, 1900.

Industrials

The southern branch of the American Steam Gange and Valve Manufacturing Company, for several years located in the Equitable building, Atlanta, Georgia, has removed its office to 524-525 Chandler building, of that city.

A. Wilson & Co., Chesford House, 98 Great Tower street, London, E. C., advises us that its agent in Ranjoon, Burma, asks for estimates of petroleum machinery, including piping, viz., a complete plant for boring for crude oil to the depth of 1500 ft. with power.

Chalmers & Williams, Inc., Chicago, Ill., advises that the latest additions to the already large list of purchasers of the Burt rapid cyanide filter are the Amparo Mining Company, Etzstian, Jalisco, Mex., and the Cherokee Goldfields Ltd., Parral, Chihuahua, Mexico.

Fred M. Prescott Steam Pump Company advises that in order to facilitate the handling of its growing business in Mexico and southwestern portion of the United States, it has opened a district office at El Paso, Texas. City National Bank building, which is in charge of W. R. Thurston.

G. M. Davis & Son, Palatka, Florida, manufacturers of cypress tanks, have issued a souvenir card entitled, "Florida Favorites," instead of the usual calendar. The orange blossoms and fruit portrayed are both tasty in design and typical of the State in which the factory is located.

Arthur Koppel Company has turned over the agency for the sale of its portable track, industrial railways, cars of all kinds, including mine cars, rails, switches, turntables, etc., in the State of Colorado to the Jeffrey Manufacturing Company, 1711 Tremont Place, Denver, Colo.

The Wagner Electric Manufacturing Company has opened a sales office in the Trust building, Charlotte, N. C., to assist in the care of its rapidly growing Southern business. The company's other office in the South is in Atlanta, Georgia, and the factory and main office, as is well known, is in St. Louis, Mo.

The Wood Drill Works announces that it has appointed Harold L. Bond Company, of 140 Pearl street, Boston, Mass., as its exclusive agents for the sale of Wood rock drills in the New England States to take effect January 1, 1909. Harold L. Bond Company has offices at 42 Broadway, New York City, in charge of Joseph C. Sealy.

The Stephens-Adamson Manufacturing Company, of Aurora, Ill., manufacturer of conveying and transmission machinery has removed its New York offices to 50 Church street. F. McVethy, who has conducted the local branch during the last two years, will return to the home office to take up the duties of assistant sales manager. William Reinecke has been appointed as manager of the Eastern office.

Edward C. Brown, manager of the Hawaiian office of the Dearborn Drug and Chemical works at 42 Queen street, Honolulu, is making an extensive oriental trip of three or four months, during which he will visit Japan, the important seacoast cities of China, Australia, the Philippines, Java and other important islands in the Pacific ocean. Mr. Brown has most successfully handled the Dearborn Company's business in the Hawaiian Islands since that department was opened, some ten years ago.

The Wood Drill Works, of Paterson, N. J., has issued a 12-page booklet entitled, "Wood Rock Drills," giving some valuable information and description of the machines showing their adaptability to tunnel driving, drilling in concrete, and open cut work; with detailed costs in driving the Tilton tunnel at North

Yakima, Wash., United States Reclamation Service, also on other engineering works with a number of fine testimonials. The booklet is printed in three colors and can be obtained at any of the company's offices in the United States, Mexico and Canada.

The Buffalo Steam Pump Company advises that it has contracted with the city of Grand Rapids to furnish ten immense sewage pumps, having a total capacity under maximum conditions of over 250,000 gal. per min. The pumps are to be placed in three stations, one station to contain two 18-in. pumps, second to contain two 24-in. pumps, third to contain two 24-in. pumps, and the fourth station four 40-in. pumps. The Westinghouse Company furnishes electrical equipment on a separate contract. The ten pumps together, without motors will weigh approximately 200,000 pounds.

The Youngstown Car Manufacturing Company, Youngstown, Ohio, builders of cars for freight and industrial service has issued an illustrated catalog with 200 cuts showing different styles of dump cars, flat cars, special cars, etc. The range and variety of the product is well shown by the catalog which includes everything from the smallest dump car and factory truck to the largest log car for iron and steel mills. Standard freight cars, sugar cane cars and logging cars are not omitted. The cover design indicates suitably that both industrial cars and freight cars are built. Size, 8x10 inches; pages, 64.

The Leschen Company's system of aerial wire rope tramways is especially adapted for the transportation of all classes of material, and is recommended for heavy capacities, long distances, long spans, and localities where very steep gradients occur. These advantages have been demonstrated in the Leschen Company's patent automatic tramway constructed for the Penn-Wyoming Copper Company, of Encampment, Wyoming, connecting its mines with the smelter, a distance of over sixteen miles and through the most rugged contour of country. This tramway has a carrying capacity of 400 tons of copper per day.

Mining engineers will be very much interested in the products of the International Asbestos Graphite Company, of Niagara Falls, N. Y. One of these products is a thoroughly amorphous, very fine, soft, unctuous graphite known as grade "1340." It is an electric furnace product and is guaranteed at least 99 per cent. pure. Because of its great unctuousness and high purity, it is a true lubricant in itself, but it can be mixed with grease or oil. It is claimed to be wholly without the friction-creating impurities of natural graphites. The company also makes a very superior line of graphitized greases in which the world's best graphite and a high grade grease and blended so that the product will do from three to four times more work than any other grease now on the market.

Announcement was made January 18 of the consolidation of the Sirocco Engineering Company, New York, with the American Blower Company, of Detroit, Michigan. Owing to the position of the American Blower Company in this line of manufacture in the United States, the announcement is of exceptional importance to engineering and commercial interests. The Sirocco fan is of English invention. In the United States the fan met competition, but has steadily advanced until it is now used in some of the most important installations in the country, for mine and general ventilation. A distinguished feature of the Sirocco fan is the drum form of the runner, which consists of a large inlet chamber inclosed by 64 long, narrow blades curved forwardly.

We are in receipt of the new catalog of engineering instruments issued by the Bausch

& Lomb Optical Company, Rochester, N. Y. Aside from its copious illustrations, this publication is of interest because of the complete specifications given for the optical and mechanical construction of the various transits, levels and theodolites. The several unique features of the Bausch & Lomb instruments are explained in a brief manner, while an entirely original mining transit is cataloged for the first time. The distinguishing features of this new instrument include a prismatic side telescope, which is novel in construction and which will be described more fully at a later date. Also with this instrument the U standard construction together with a compass circle of the usual form is introduced. The catalog is sent gratis upon request.

The Traylor Engineering Company has opened offices in the Farmers' Bank building, Pittsburg, Penn., and George T. Ladd, who has been associated with some of the largest manufacturing industries in this country for the last twelve or fifteen years, is to have charge of same. The offices have already been established, and it is understood that Mr. Ladd will be elected one of the vice-presidents of the Traylor Engineering Company early in January at the annual meeting of the stockholders. On account of the very satisfactory business that the company has done in Pittsburg and that vicinity, it believes that an office at this point will be suitable for covering all of the middle western territory. It is also understood that the company will establish, under Mr. Ladd's management, an office in Chicago. The company has one of the most complete sheet-metal working departments to be found anywhere in the country, and a foundry with 100 tons capacity, and on account of the very great demand for both sheet-steel work and large castings, it will doubtless be able to supply a very large portion of this class of business all through the middle West. The Traylor Engineering Company manufactures all kinds of mining and metallurgical machinery. It has also recently arranged with L. C. Trent, one of the best known mechanical and metallurgical engineers in the machinery trade to represent it. Mr. Trent has probably more experience in the manufacture and sale of mining and metallurgical plants than any one man in this country. He is to open an office for the Traylor Engineering Company as manager of the Pacific western territory, having an office in Salt Lake City, beginning the first of January, 1909; also an office in Reno, Nevada, and one in San Francisco, California.

NO. 6.

Ore Formation in the Wonder District, Nevada

The Silver Minerals Are Found in Lines Following the Direction of the Veins Which Vary from a Fractured Zone to a Solid Quartz Lode

BY ETIENNE A. RITTER*

The Wonder mining district is situated a little south of the center of Churchill county, Nevada. It is reached by stage from Fallon, on a branch of the Southern Pacific railroad, the distance from Fallon being 55 miles. Wonder is 12 miles from the mining camp of Fairview. It is situated on rolling hills on the western slope of the Augusta mountains, which belong to the Basin ranges. These mountains form a long and narrow ridge, bearing almost directly north and south, with a gentle slope to the east and a steep slope

ROCKS AND MINERALS

The mineralized territory of the Wonder district has an area of about six miles square. It is in the heart of a vent of very acidic eruptive rocks, with small areas of andesites, and larger areas of trachytes, cut by large dikes and masses of rhyolites. It seems that here, as in the Cripple Creek volcano, it is possible to find all the types of rocks passing by the most complete series of gradations into one another from the andesites to the rhyolites.

carlsbad twinning. The ground-mass is made up of microscopic crystals of quartz displaying several types of the felsitic structure. They are either in small groups of crystals with the same optical orientation and extinguished together, or they form long needles radiating from a central point and having characteristics of some varieties of quartz porphyries.

The veins run in a general northeast-southwest direction. They are similar to those of the Tonopah mining district, both in the physical characteristics of the frac-

WONDER, NEV., FAIRVIEW MOUNTAIN ABOVE FAIRVIEW CAMP IN THE DISTANCE

to the west. They were formed by the tilting of a block of strata along a line of deep faulting. Along this line of great faulting enormous masses of eruptive rocks have been poured out, and among them the trachytes and the rhyolites which form the hills of the Wonder district. During a later geological period the large, sandy valley into which the Wonder hills descend, was an arm of an immense inland sea. Today its dry bottom is a desert expanse.

The andesites are rare and thoroughly altered. The trachytes are much more abundant and in a better state of conservation. The phenocrysts of orthoclase and of oligoclase are fairly fresh; the biotite has been altered into chlorite and epidote to a great extent. The ground-mass has been so charged with decomposition products and so colored by limonite, that it is difficult to recognize its constituent minerals. The rhyolites show phenocrysts of quartz and of orthoclase well formed. They show only occasionally

tures and in the way the mineralizing waters have ascended through them.

In the Wonder district, the rocks were complexly fractured and many of the veins split up in two or more branches, as is the case, for example, in the Wasp and Stray Horse veins. The circulation channels were not made by open fissures; they were only fractured zones, through which the circulating waters ascended. As a result, the veins show all the stages in the change, from a fractured zone in trachyte or rhyolite, to a solid quartz vein. This main

*Mining engineer, Colorado Springs, Colo.

feature of the ore deposits of the Wonder district is shown in the accompanying illustrations of rock sections.

VEIN STRUCTURE

In the extreme case, the vein consists simply of a zone of more or less altered trachyte or rhyolite, only a little richer in quartz than the same country rock, which forms the walls. The silver and gold minerals are closely associated, not only with the quartz, but also with the micas and the feldspars. In Fig. 1, ore from the Big Vulture vein, the stephanite is segregated in the ground mass in the same way as the micas and the feldspars. No orientation of any of the minerals, along the direction of the vein, can be seen.

The mineralized zone, which forms the

scopic section is that crystals of calcite are closely associated with the silver minerals; no other crystals of calcite have been found in any of 20 or more sections of rock examined. It shows conclusively that the mineralizing waters, which have deposited the Wonder ores were rich in carbonate of lime.

In the next step the metasomatic action of the mineralizing waters is plainly shown. The feldspars and the micas have disappeared, or they have been completely transformed into new products, like sericite, and others not well enough crystallized to be identified under the microscope. Nevertheless the banded structure, so characteristic of the open fissures filled by crustification cannot yet be found. Often the main wall fractures, being the larger ones, have been the main channels of cir-

a greater fracturing of the whole rock mass between the two walls, veinlets of quartz cross from one wall to the other, until they form a complete, and finally so close, a network, that the whole mass has been transformed into a solid quartz vein. In this last case the silver minerals instead of being scattered in a haphazard way, in the rock, partake of the general orientation of the quartz. They are found lined up along some main channel of deposition, as can be observed in the accompanying microphotographs, showing ore from the Wasp and from the Wonder veins.

The first shows ore from the Wasp vein, without analyzer; it shows in black the silver sulphides lined up in a well marked direction. That shown in the second is the same section with the analyzer on,

MICROPHOTOGRAPHS OF ORE FROM THE WASP AND WONDER VEINS

NEVADA WONDER SHAFT

JACK POT MINE

vein, is cut by fractures usually parallel, having the same dip and strike as the walls; the walls are stronger breaks only, of the same kind, which limit the zone of fracturing. In Fig. 2 ore from the Little Vulture and Queen No. 11 vein, the quartz begins to predominate over all the other minerals put together. But no lining of the silver minerals in a special direction can yet be recognized as is the case in Fig. 3, which shows a section of the Jack Pot vein. In this case, the micas have disappeared from the vein rock; the feldspars occur only sporadically, and the silver minerals have a more or less marked lining along the general trend of the vein. A very interesting feature of this micro-

culution for the mineralizing waters, and the vein shows a zone of little altered trachyte between a hanging wall and a footwall streaks of quartz. Fig. 4 shows ore from the Queen vein on the footwall-quartz streak. In this case the silver minerals have crystallized last into the spaces left by the large crystals of quartz. Fig. 5 is from the Bald Eagle vein, showing large crystals of quartz, which have been fractured and filled by submicroscopic silver minerals. The interesting feature is that the quartz crystals have been broken after solidification, and that the ore lining shows the fractures passing without break from one quartz crystal into another.

With the last step, usually favored by

showing the lining of large quartz crystals parallel to the silver sulphides. Nothing is seen except the silver sulphides and the quartz in large and small crystals; the micas and the feldspars have disappeared. The third microphotograph, from the Wonder vein, shows without the analyzer, the silver minerals well lined up. In the fourth the analyzer was employed. It shows the quartz in small crystals so well lined that they form a veinlet showing crustification, in the heart of which the sulphides are lined up.

The various conditions I have just described of a vein, simply formed by a set of parallel fissures across the country rock, are found in every one of the well

known veins of the Wonder district. In each of these veins, there are places more or less barren, which are characterized by the lowest stage of metasomatism and accompanying ore deposition. The transformation of the rock between the parallel sets of fissures increases more and more as an oreshoot is approached. In the oreshoot itself, the transformation has become complete.

THE CAMP

The district was discovered on March 15, 1906, by Thomas J. Stroud. He located the Lost claim, and during a second trip the Jack Pot group. On a third trip,

and some others. The wages are those of the Tonopah scale, \$4 and \$4.50 per day.

Two railroad lines have been surveyed into the district; a branch line from Fallon, by way of Fairview, and one south from Winnemucca. A pipe line from Bench creek brings 150,000 gal. of water in 24 hours.

Coking of Coal with Fine Ore at Cerro De Pasco

A novel method of treating fine ore by smelting is in use at Cerro De Pasco,

Magnesite in California

SPECIAL CORRESPONDENCE

The new magnesite mines of the Tulare Mining Company at South Tule, in Tulare county, Cal., are showing up good quantities of ore, and if present indications are borne out, other calcining furnaces will be put in and preparations made to market the ore on a larger scale. The old mines at Porterville have some 1100 ft. of tunnels but the deposit is in such a condition that the cost of mining has been in-

FIGS. 1, 2, 3, 4 AND 5. SKETCHES OF VARIOUS ORES FROM THE WONDER DISTRICT

In order from left to right, beginning at the top, the sketches represent: Ore from the Big Vulture vein, showing trachyte; the surface of the Little Vulture vein, showing the first stage of the mineralization; ore from the Jack Pot vein, showing calcite in groundmass of small quartz crystals; the Queen vein, showing ore filling interstices between large crystals of quartz; Bald Eagle, showing large quartz crystals broken and filled with microscopic lines of ore.

he was followed by several parties of prospectors, who located the Nevada Wonder and the Queen groups. It was a month later that some exceedingly rich ore in shipping quantities was found. Then the rush began and the town of Wonder sprang up in a few weeks, with two banks, two newspapers, two hotels, an artificial ice plant, and, of course, many stores and a greater number of saloons.

The camp suffered from the business depression of last year, like all the other camps of Nevada; but is doing much better now and has perhaps 200 men at work on seven or eight properties, the Nevada Wonder, the Queen, the Jack Pot,

Peru. It consists in mixing the ore with coal and coking the coal. The coke being used in the smelting furnaces, the ore that it carries goes into the process in that way. The mixture consists of 25 per cent. by weight of fine ore and 75 per cent. of raw coal. The raw ore assays 22.36 per cent. silica, 20.90 iron, 9.75 copper, 5.08 alumina, 4.1 lead, 3.2 zinc and 24.58 sulphur. The raw coal analyzes 25.4 per cent. ash, 39.85 volatile matter and 34.75 fixed carbon. The coked product, after being coked in ordinary bee-hive ovens for 48 hours gave the following analysis: 8.2 per cent. iron, 3.11 copper, 4.41 sulphur, 33.9 ash, 2.07 volatile matter and 54.09 fixed carbon.

creased. Both mines really belong to the Willamette Paper and Pulp Company and it is probable that the supply for the paper mills will shortly be drawn entirely from the new deposits at South Tule. It is thought by the owners of these and other magnesite mines that if Congress imposes the duty asked for, they can ship to eastern points at a profit. The Fresno Magnesite Company has recently opened a mine in that county and has installed furnaces for furnishing calcined material to be made into articles for building purposes. The company is not selling to the paper mills, as the owners of these mills on this coast now own their own mines.

The Progress of Gold Mining in North Carolina

The Mines Which Were Large Producers Prior to the Civil War
Are Again Attracting Attention; Many of Them Have Been Re-opened

BY EDWARD WEST LYON*

HISTORY

Gold was produced in the Southern Appalachian States before the Revolutionary War by the Cherokee Indians and others; the first gold minted by the United States Government in 1793 was mined in North Carolina. Estimates compiled from reports of the United States mints including the three mints established in the Southern States prior to 1848, at New Orleans, La., at Dahlonega, Ga., and at Charlotte, N. C., in 1837, and from State reports, show that the gold and silver production of the Southern States from 1799 to 1908 amounted to \$49,000,000. Of this, 80 to 90 per cent. was gold, having a fineness varying from 750 to 980. North Carolina is credited with \$23,000,000;

Gold nuggets were of frequent occurrence in early as well as later operations; the largest of these nuggets on record weighed 28 lb., and was found at the Reed mine, North Carolina, in 1803. Up to the middle of the last century most of the gold was produced from irregularly worked placers and similar detrital deposits, such as gravels in beds of streams, or on hillsides, surface gravel, and the gossan outcrops of the veins. To work these deposits required little skill and only a few cheap appliances, such as pans, sluice boxes, log rockers, arrastras and Chilean mills with "dolly tubs," these being

and yielded then from \$2 to \$6 per ton with open-cut mining and Chilean mills. At a few of the mines the quartz veins were worked to a depth varying from 100 to 500 feet.

The greatest mining activity occurred between the years 1829 and 1849; after that date, owing to the discovery of gold in California, there was a considerable exodus of Southern miners to the newer fields. Wooden stamp mills, as well as iron stamps with a few Cornish buddles for concentrating the auriferous and copper minerals in the sulphide ores, were in use when, in 1861, the Civil War stopped all mining operations. Before that time several North Carolina mines

CATAWBA MINE; A SCHISTOSE ORE DEPOSIT

SAWYER MINE, GRIZZLY AND WATER FEED

Georgia with \$18,000,000; the rest came from South Carolina, Virginia, Alabama, Tennessee and Maryland.

Gold was extensively coined between 1831 and 1857 by the Betchler family at Rutherfordton, N. C., until stopped by the Government. Their \$1, \$2.50 and \$5 coins are now rare, as most of them were remelted with profit. During this time much gold was sold to country storekeepers; some of this was sent to the mint, but probably a considerable amount does not appear in the mint reports as coming from the Southern States.

usually run by horse whim or water power. Over limited areas some of these placer deposits yielded from \$100 to \$200 per rocker per day. Usually the gravel carried from 50c. to \$2 per cubic yard.

Prospecting led to the discovery of the veins and the wide, lower-grade belts of silicious schists and slates that were the sources of the placer gold. The quartz veins, according to the report for 1856 of the State geologist of North Carolina, Mr. Emmons, were in places from 2 to 8 ft. wide, and contained or yielded at that time from \$10 to \$100 per ton; the schistose deposits were from 20 to 60 ft. wide,

had been worked to a depth varying from 250 to 700 ft., and had produced from \$200,000 to \$2,500,000. Among these were the McCulloch (or Lindsay), the North State, the Phoenix, the Howie, the Hanover Hill, the Russell, the Jones, the Loftin (or Herring), the Rudisil, and the Gold Hill mines. Among the placer mines, the Portis had a recorded production of more than \$1,000,000.

Mining was resumed by a new, inexperienced generation between the years 1870 and 1880. Since then there have been several spasmodic revivals, with intervening periods of depressions and irregular

*Mining engineer, Greensboro, N. C.

work. Nevertheless, the production has been considerable for the amount of development at the few locations worked.

In many cases where hydraulic mining, or where the modern stamp mill was used, the fineness of the gold and the slimes in the ore prevented a recovery of more than 40 to 60 per cent. But now an extraction of from 80 to 95 per cent, is possible from the soft ores by new pulverizing and washing methods, and from the hard ores by either the barrel chlorination, pyritic smelting, or the more recently perfected cyanide process. The cyanide process has recently been used successfully at the Iola mine, North Carolina, on free ores containing \$15 to \$20 gold per ton. The Modern pulverizer and concentrator washing process is used at the Catawba mines, North Carolina, on a schistose ore carrying 60c. per ton, and the barrel chlorination method at the Haile mine in South Carolina on pyrite ore carrying \$2 to \$4

reasons, and because of its being such an old and accessible field, to advise investment in, or even investigation of, mines in the South.

Consequently, the recent discoveries and the possibility of other discoveries, the new development proving the persistency of orebodies in these fissure and contact veins, and the increased profits obtainable from the application of new extraction methods to these ores, are being neglected.

GEOLOGICAL OCCURRENCE AND MINERALOGICAL CHARACTER OF NORTH CAROLINA OREBODIES

The auriferous deposits of North Carolina are contained in the crystalline rocks, that, according to the geologists, cover one-half the State. The rocks include gneisses, metamorphic argillaceous, sericitic and chloritic schists, slates, siliceous limestones, igneous plutonic rocks, such as granites, diorites, diabases, as well as

of larger and smaller lenticular bodies, generally conformable to the schistosity of the rocks, but sometimes intersecting the schists, usually at small angles. These veins vary in width from 1 to 8 feet.

The impregnation of free gold and fine-grained auriferous sulphides in the country schists and slates are sometimes accompanied by small intercalated quartz lenses. These schists are sometimes hundreds of feet in width, but usually only a portion of their width carries sufficient mineral to pay for mining. It is these large schistose orebodies that form the low-grade deposits of North Carolina and the other Southern States; from them considerable gold has been produced.

In both the veins and the schists, the ore generally occurs in chimneys and shoots. The general strike of the schistosity is north 20 to 55 deg. east, and the dip varies from 55 to 85 deg. toward the northwest. Most of the veins have a

GEOLOGICAL MAP OF NORTH CAROLINA, BASED ON MAP MADE BY NORTH CAROLINA GEOLOGICAL SURVEY

per ton. Some of the ores can also be successfully smelted.

PRINCIPAL CAUSES OF DECREASED PRODUCTION

While the changing of the surface ore to refractory sulphide ore at greater depth, or the impoverishment of the orebodies at depth have caused some failures, many of these have been caused by poor management; by the adoption of experimental processes that in the end proved commercially unsuccessful; by the erection of mills before the orebody had been sufficiently developed; or by starting with a capital too small to provide for correcting initial mistakes.

These failures have given the Southern field a bad reputation among mining operators and investors, and many mining engineers, not having personally examined its history and record, its geological formations and ore deposits, hesitate on account of the before-mentioned

ancient volcanics, such as rhyolite, quartz-porphry and pyroclastic breccias. The limestones and some slates show sedimentary origin, but all are so metamorphosed that they may be included under the general term of crystalline rocks. They appear to be Archean, Algonkian and, in part, Paleozoic in age; in geological literature the slates characteristic of southeastern Montgomery and Union counties have been called the "Monroe slates."

Structurally the ore deposits are of two principal types: the quartz-filled veins and the impregnated belts of schist and slate. The gold in the quartz veins occurs both free and in the iron, copper, and other sulphides. The veins differ greatly in mode of occurrence. Some are clean-cut fissures in the massive and the schistose rocks, intersecting the latter, both in dip and strike, at a well defined angle; others occur along contacts between the granites or diorites, and the schists or slates, while still other veins are composed of a system

northeast-southwest strike and dip to the northwest. The rocks of the gold belt are much decomposed. The veins are often oxidized to a depth of 100 ft. and in some instances, as at the Iola and Cagle mines in North Carolina, the ore in the vein is oxidized or carries free gold to a depth of several hundred feet, while the inclosing wall rocks carry sulphides.

GOLD BELTS OF NORTH CAROLINA

The North Carolina field may be divided geologically and geographically into three main belts: the Eastern Carolina belt, the Carolina belt and the South Mountain belt. The Eastern Carolina belt forms a small area in Halifax, Warren, Nash and Franklin counties; it is bounded by the coastal plain and the Louisville granite. The country rock is diorite, in places changed by shearing into a chloritic schist; other intrusions, some of diabase, occur. The quartz veins vary in width

from a few inches to several feet. They occur in the schists and also along the contact of slates and granite. In places, the surface soil near the veins carries sufficient fragmentary quartz to make it minable. In this area there are some rich placers.

The Carolina belt is subdivided into the Carolina Slate belt and the Carolina Igneous belt. The Carolina Slate belt, which is composed of argillaceous and sericitic slates, crystalline schists, rhyolites, quartz-porphyrines, andesite and pyroclastic breccias, is from 8 to 50 miles wide and extends in a southwesterly direction across the Central Piedmont section of the State. It is called by Emmons, one of the former State geologists, "the Taconic," and by Kerr, a successor of Emmons, "the Huronian" belt. In this belt occur fissure and contact veins containing auriferous quartz. Such veins have been worked at Gold Hill, Hoover Hill and other mines. There are also in this belt wide low-grade impregnations of the schists and slate, in which the gold occurs both free and in pyrite as at the old Russell, Jones, Lafflin, Empire, Pine Hill

are crystalline schists and gneisses in which lenticular bodies of silicious magnesian limestone and beds of quartzite occur occasionally. Pegmatite dikes are found in the King's Mountain district in Gaston and Cleveland counties; some of these dikes are tin-bearing. In this belt the ore occurs not only in fissure veins, but also as impregnations of the silicious, magnesian-limestone intercalations in the mica schist. The old King's Mountain mine (Old Catawba), which produced several hundred thousand dollars, is an example of the latter form of deposit. The schists or gneisses at the Catawba (Old Shuford) mine in Catawba county are profitably worked to a width of more than 100 ft. and to a depth of 90 feet.

The East Blue Ridge belt has an area of 250 to 300 square miles, and is principally on the eastern side of the Blue Ridge mountains in Burke, McDowell, Rutherford and Caldwell counties. The crystalline rocks are for the most part micaceous and hornblende gneisses and schists that often contain garnet and sometimes zircon and monazite. Pegmatite and also granite and

THE IOLA MINING DISTRICT

The Iola mining district is a comparatively new district near Candor, Montgomery county, N. C. The Iola, the principal mine in the district, has produced over \$300,000 in gold since its discovery in 1901. This mine was first worked with Chilean mills, then a 10-stamp, and later a 20-stamp mill and a 40-ton cyanide plant were erected to treat the ore. The Iola Mining Company owns about 65 acres covering approximately 2000 ft. along this vein. Recently a 40-stamp mill equipped with concentrating tables has been completed; the cyanide plant is now being moved and re-erected with additional tank capacity below the new mill. The production for April, when the mill was operating at only about three-fourths its capacity, is stated to be \$9000. The country rock is a greenstone of slaty character, probably a sheared andesite. A dike, resembling basalt, and running at right angles to the country, occurs not far from the adjoining Golconda mine.

The surface soil near the veins is sandy and shallow. Although the ore outcrops

MODERN PULVERIZER AND CONCENTRATOR

and Haile mines. At the Parrish mine the gold ore is an impregnation of actinolite and tremolite.

The Carolina Igneous belt is west of the Carolina Slate belt. It is from 15 to 30 miles wide, and extends southwesterly across the State through Guilford, Rowan, Mecklenburg and other counties. The rocks in it are granites, diorites, gabbros and diabases cut by later, granitic and diabasic dikes. Schistose or gneissic structure is developed at places. In this belt the gold-bearing quartz occurs in fissure veins, several feet wide; the gold occurs free and in the sulphides. Often, these gold ores are cupriferous, sometimes carrying from 3 to 20 per cent. copper. The old Fentress and Gardner Hill mines, the McCulloch, North State, Lindsay, Fisher Hill, Phoenix, Reed and Rudisill mines are in this belt.

THE SOUTH MOUNTAIN BELT

The South Mountain belt is subdivided into the King's Mountain belt, East Blue Ridge belt and the West Blue Ridge belt. The King's Mountain belt adjoins the Igneous belt on the west and passes through Gaston, Lincoln, Catawba, Yadin and other counties. The country rocks

diabase dikes occur. This complex is cut by a system of parallel quartz fissures, containing free gold and auriferous sulphides. These fissures vary in width from 1 in. to 4 ft., and many fissures are only 1 to 3 in. wide. These veins strike north 60 to 70 deg. east. Some of them have produced high-grade gold ore. Near the veins some of the saprolites are auriferous. The principal mining ground is composed of the placers, the gravel deposits in the stream beds, gravel in hillsides and gulches, and the saprolites.

A large amount of gold has been produced by sluicing and hydraulicking in the Brindletown district in Burke and Rutherford counties. Where washing or sluicing is now being done, the gravel carries from 20c. to several dollars per cubic yard.

In the West Blue Ridge belt the ore deposits are scattered. The country rocks are mica and hornblende schists; these are cut by granitic dikes. At Boylestown, Henderson county, limestone underlies the schists. The principal mines of this belt are in Swain, Jackson, Macon, Clay and Cherokee counties, where placer-mining operations are carried on. The country rock is supposed to be mainly Ocoee in age.

in one place only, the vein can be traced by iron-stained quartz float along its strike, which is approximately north 40 deg. east. The vein varies from 2 to 6 ft., and averages $2\frac{1}{2}$ to 3 ft. in width; it dips 45 to 50 deg. toward the northwest. The only outcrop of the vein occurs at the discovery shaft. At the surface the ore is a hard, milky quartz, showing visible gold, but a few feet deeper the vein matter became soft and changed to a slaty quartzite ore carrying some lime spar between distinctively slaty walls. Quartz did not appear in the vein again above a depth of 130 ft. In other shafts pay-ore was not encountered until a depth of 30 to 50 ft. was reached. A few faults of small displacement have been encountered underground, but as yet no cross-vein or dikes. Down to 327 ft., the present depth of mining, the gold is fairly evenly distributed in the vein; nearly all the gold is in a free state, the vein carrying only a small amount of sulphides. A good deal of sulphide impregnates the wall rocks; this is unusual at Southern ore deposits. The gold, although fine, is usually granular. Pay-ore has been developed along the vein for 650 ft. by four shafts but drill

holes have extended the length of the known pay-ore 150 ft. farther southwest.

PERSISTENCY OF THE ORE

The persistence of the ore is shown at the main or No. 1 vertical shaft, which cuts the vein at a depth of 265 ft. and follows it 72 ft. deeper. Crosscuts have been run from this shaft at the 150- and 200-ft. levels; drifts have been driven on the vein and some stoping has been done. On the 255- and 327-ft. levels north and south from this shaft, the highest grade of ore in the mine, much of it showing visible gold, has been developed. Samples from these levels assay \$35 to \$45 per ton. Recently, some of this ore has been mined and milled, but on this level a considerable reserve of ore remains. No. 2, a vertical shaft, 333 ft. southwest of No. 1, cuts the vein at 115 ft. and follows it 50 ft. deeper; drifts have been driven from it in both directions on the 116-ft. level. The No. 3 shaft, 150 ft. deep and 214 ft. east of No. 1 shaft, was sunk to work a body of high-grade ore developed in the discovery incline that has since caved; most of this ore has already been mined. No. 4, a new incline shaft sunk on the vein to the southwest of No. 2, is 180 ft. deep; it is in a pinch of the vein, which for the last 20 ft. has been only 15 in. wide. This shaft, which is located near the new mill and is to be the main working shaft, was started to be sunk to a depth of 600 ft.; work on it has been suspended.

These developments have proved a considerable reserve of ore. While the driving of drifts to the southwest may add to this reserve more rapidly than it is required to supply the mill, still, either the new No. 4 combination shaft or the No. 1 shaft should be sunk several hundred feet so as to develop the vein at greater depth, for the Iola vein warrants such development.

Sullivan and Rand drills are used in mining the harder ore. The Mecklenburg Iron Works 8-in. Cornish pump at No. 1 shaft does all the pumping. A 3-in. pipe line, 1½ miles long, supplies water for milling. At surface, and also underground, electricity generated at the mine is used for lighting. The different engines at surface are run by steam.

The ore is delivered to mill from No. 1 and No. 3 shafts in cars by cable and from other opening by barrows. It is fed by hand to the 40 stamps, that weigh 700 lb. and crush through 50-mesh screens. After passing over amalgamating plates, 16 ft. long, and shaking tables, the pulp which carries \$4 to \$6 gold per ton goes in flumes to the cyanide plant. The stamp duty is a little over one ton per stamp in 24 hours.

At the new 60-ton cyanide plant the usual method of agitation and decantation will be used in treating the slime and the sand will be leached in small tanks. Compressed air will be used in the agitators to

loosen the slime before throwing into gear the agitation clutches. The sand from the separators will be partially dried on a dump before loaded into the leaching tanks, lime being added to the sand as the tank fills.

Such were the plans a few weeks ago, but since then a receiver has been appointed to take charge of the Iola Mining Company, mainly on account of mismanagement previous to April, 1907.

MONTGOMERY AND GOLCONDA MINES

The Montgomery mine adjoins the Iola on the northeast and contains the extension of the Iola vein in that direction. The main shaft at the property is 235 ft. deep; on that level considerable work has been done on two veins, one having the general character and grade of ore as the Iola vein. The property is equipped with a 10-stamp mill and cyanide plant. This mine is not being worked at present, but the water is being kept down. A new shaft, several hundred feet from the present openings, was recently started.

The Golconda mine adjoins the Montgomery; its workings are on a vein, 2 to 6 ft. wide, east of and parallel to the vein in the Iola and Montgomery properties. It is opened by an incline shaft 150 ft. deep from which levels have been driven at depths of 50, 100 and 150 ft. Some of the ore exposed assays \$15 to \$20 per ton, but, as the mine was full of water, examination of the deeper workings was impossible. The ore differs from the Iola ore in its brownish color and quartz character; it also contains considerable sulphide. The dike, outcropping in its vicinity, possibly has played a part in the genesis of this vein. The mine and its 10-stamp mill are idle.

Neither the northeasterly or southwesterly extension of the Iola district has been prospected much, but identical iron-stained float and gold-bearing gossan or gravel is known to exist at several locations. Recently a new development company has been buying property on the northeastern extension of the vein.

By drill holes, new coal measures have been found in brown sandstone and shales within 15 to 20 miles of the Iola district. This find may develop into a source of cheaper fuel for that part of the State.

CATAWBA MINE

One of the low-grade schistose mines is the Catawba, situated four miles from Catawba, N. C. This mine produced considerable gold by crude washing and milling methods, but when hydraulic mining was tried, the undertaking proved a failure. Its massive decomposed schistose and gneissic formation, intersected at places by small quartz seams, is opened and the entire width mined by an open cut several hundred feet long, 100 to 150 ft. wide, and 50 to 90 ft. deep. The ore is free milling, and its average gold content is 60c. per ton.

At present the ore from this mine is profitably treated with a stated extraction of 80 to 90 per cent. by the new Modern pulverizer and concentrator. This machine was adapted to treat this class of ore, and was installed at the mine by the mine superintendent, A. J. Overton, about three years ago. The cost of mining and treatment is said to be from 15 to 25c. per ton. One set of pulverizers and washers, shown in an accompanying cut, was installed at first, but additions have been made until four sets, with sluice boxes, are now in operation. From 160 to 200 tons are washed in 10 hours; it is claimed that 300 tons per 10-hour day have been mined and washed. The property is not operated at night.

The Modern pulverizer and concentrator is an improvement on the old Snodgrass washer, which in the newer machine has been adapted to the treatment of schistose and placer formations. This device is a combined disintegrator, pulverizer, concentrator, scourer and washer; it saves a high percentage of the coarse and finer as well as the flour gold. The machine consists of two iron concaves, the first 18 ft. and the second 12 ft. long, with revolving shafts, extending through each washer. The shafts make from 150 to 250 r.p.m., and to them are bolted a series of spirally arranged iron or steel blades. The machines discharge, near the bottom of the lower ends, through 1-in. and ¼-in. revolving screens, respectively. Any lumps or uncrushed rocks go to a belt conveyor; the pulp that passes through the disintegrator goes to sluice boxes.

The feed ends of the machines are set 8 in. and 4 in. higher, respectively, than the discharge end; the sand and fine gravel accumulates, and the free gold is recovered where it settles near the upper end of the disintegrators. Most of the gold is caught in the 4-in. space below the concaves, and from 60 to 70 per cent. of gold is caught in the first machine. In the weekly cleaning-up, the concentrators are discharged through an opening in the bottom. Quicksilver is used only in the riffles and in the crude clean-up boxes.

METHOD OF MINING

The ore is delivered from the open cut by cable in one-ton wooden ore cars and in large scoops to the grizzly on the side hill above the mill. One man sledges the oversize from this grizzly. At present the ore from the grizzly is flumed with 3-in. and 5-in. water lines under a head of 35 ft., to the washers about 200 ft. distant, but the company will soon move the washing plant several hundred feet below the present site so that the ore can be delivered by gravity from the mine to the washers, thus avoiding maintenance and cost of their present hoisting plant and delivery method.

The mill and hoist are operated by a 200-h.p. boiler and a 70-h.p. engine. A

pipe-line $\frac{3}{4}$ mile long supplies water from a dam, which also catches the water draining from the tailings. From the dam the water is pumped to the grizzly. The necessary equipment for the four-washer plant, including buildings, power, pumping outfit and mining equipment, probably cost, erected, between \$20,000 and \$25,000.

The capacity of one pair of washers is rated at from 40 to 100 tons in 10 hours. One pair requires 75 gal. of water per minute, and from 15 to 25 h.p. to operate it. The price per set of two machines, including shafting, is \$1750 f.o.b. Chattanooga, Tenn. The erection and equipment of an ordinary one-set plant, including power, buildings, water, etc., costs approximately \$5000. By using crushers to break the ore before it goes to the washers, the harder types of schistose ores may be cheaply and efficiently treated with this washer.

Working tests with one set of machines at both the Sawyer and the Parker mines showed a good recovery in the machines, but large losses occurred through careless or crude clean-ups of the gold-bearing sands and concentrates.

The use of Pierce separators and amalgamators below the washers, when maximum tonnage is desired, and the use of a modern clean-up pan are recommended. The clean-up pan will prevent the loss in the clean-ups of the gold saved in the machines.

The Catawba Mining Company owns and controls several hundred acres along the northeastern extension of their ore deposit, so that the company is considering an addition to their plant.

SILVER, COPPER AND TELLURIUM ORES

Silver ore is found at few places in North Carolina. At Silver valley the lead carbonate and the galena associated with zinc blende are argentiferous. The old Silver Hill mine, at that place, was worked to a depth of 735 ft. by the Confederate Government, in order to obtain lead for bullets. Native silver has been found in this mine.

Tellurium has been found in the ores of the Belle mine, Montgomery county, and also at a new location in Halifax county in the Eastern Carolina belt.

The 1906 State report shows that the gold production of North Carolina comes from 34 counties; in the State there were, not including minor operations, nine placer mines and 15 $\frac{1}{2}$ deep or vein mines operating; the yield per ton of ore milled was \$7.70. The number of mines under development or operation is, therefore, less than during the last few years.

The copper produced from North Carolina ores comes mainly from gray copper and bornite ores in Person county and from chalcopryite ores in Rowan county. From 1900 to 1907, there was produced 3,763,916 lb. of copper, valued at \$658,519. The production for 1906 was 582,200 lb., valued at \$135,829. This is an increase in

value of 81 per cent. over the 1905 production, due partly to the higher prices of copper prevailing during that year. Incomplete figures tabulated by United States Geological Survey from reports of the production and value of gold, silver and copper from 18 counties in North Carolina gotten directly from the principal mines, shows a total production for 1907 of \$212,909 against \$288,781 for the year 1906.

	1907.	1906.	Decrease.
3,976.08 oz. gold.....	\$ 82,193	\$122,008	\$ 39,815
21,666 oz. silver.....	14,300	30,944	16,644
582,082 lb. copper.....	116,416	136,829	19,413
	\$212,909	\$288,781	\$ 75,872

Decrease in pounds copper produced was 127 lb.

In spite of this decreased production, at several new properties prospecting and developing have been started during the present year. Among these are the Morehead property, containing a silver-lead-zinc ore, in Davidson county, the Gray gold property in Guilford, the Portis gold mine and other properties in Catawba and Rutherford counties.

American Crude Oils

The accompanying table, taken from the *Petroleum Review*, Aug. 15, 1908, which states that the table is only an approximation, gives a good idea of the composition of the crude oil from the different oilfields in the United States.

Products.	APPROXIMATE COMPOSITION OF THE CRUDE OILS OF THE UNITED STATES							
	Appalachian.	Lima-Indiana.	Mid-Cont.	Gulf.	California.	Corsicana.	Colorado.

Trial of the Karns Tunneling Machine

(SPECIAL CORRESPONDENCE)

Recently I made a trip to Magnolia, nine miles from Boulder and 39 miles from Denver, to witness a trial of a newly installed rock borer, known as the Karns rotary tunneling machine. The trial was made at a mine owned by one of the gentlemen who financed the drill company.

The cutting head of the drill is 6 ft. in diameter; the power is furnished by a Rand Imperial compressor, giving about 1500 cu.ft. of air per minute. The entire machine weighs about 10 tons; the head and shaft, or in other words, the reciprocating parts, weighing 5 $\frac{1}{2}$ tons, and the carriage the rest.

The water, which was thrown against the breast, and which carried the "muck"

back of the machine, was furnished from a reservoir by a No. 9 Cameron pump, through a 4-in. pipe, reduced to 2 in. at the discharge.

We arrived at the mine at 1 p.m., and the machine was at once started up, with the result that in 90 min. of actual drilling time it bored a hole 6 ft. in diameter 6 $\frac{1}{4}$ in. into solid granite; the measurements were carefully made by disinterested engineers in the party. The entire time occupied in drilling the hole was 110 min., but the screw was moved up twice, taking 10 min. each time. The machine can cut from 4 to 5 ft. without being advanced, but in this trial, it was put forward twice in the 5 ft. 4 $\frac{1}{4}$ in.

There were, as far as I could see, no parts of the machine that were weak or liable to breakage; the moils or cutting points, of course, became dull, as any drill would, but these can be easily replaced with sharpened ones. The water and a sort of endless-chain rake in connection with the device brings the "muck" back of the machine, but the conveying for long distances to the mouth of the tunnel of the two tons of chippings per foot of advance has yet to be reckoned with. Automatic conveyers are being perfected, and doubtless this want will soon be filled.

At any rate, the cutting power of the machine was amply demonstrated—further I cannot say, for its durability under a long period of work has yet to be proved.

Gold and Silver in New Zealand

The Mines Department reports the exports of gold from New Zealand for the full year at 508,210 oz. bullion in 1907, and 506,417 oz. in 1908; a decrease of 1763 oz. The bullion reported in 1908 was equal to \$9,758,197, or 472,095 oz. fine gold.

Silver exports for the year were 1,562,603 oz. in 1907, and 1,731,366 oz. in 1908; an increase of 168,763 oz. This silver is chiefly from the gold mines of the Ohinemuri district.

Rusty gold concentrates from blanket tables are amalgamated (*Journ.*, Met., Chem. and Min. Soc. of South Africa, Nov., 1908) by treating them for four hours with nitric acid in a revolving amalgamation barrel. After that treatment, upon adding mercury, the gold amalgamates readily.

Prevention of Accidents in Metal Mines

Accidents Due to Carelessness Are Preventable. It Should Be the Duty of the Superintendent to See That the Miners Are Not Careless

BY CLAUDE T. RICE

Falls of ground, reckless handling of explosives, and carelessness at and in the shaft are the three principal causes of accidents in metal mines. Carelessness in the shaft causes many accidents; explosives cause more; and falling slabs of rock the most. Many of these accidents can be prevented by study and foresight; yet the discussion of this subject of mine accidents is shunned by mining engineers—possibly because they hate to acknowledge how many accidents are due to poor management.

The one book treating of mine accidents and the articles which occasionally have appeared deal mainly with accidents at coal mines, while the little that has been written on accidents at metal mines consists mainly of statistics regarding the frequency of different classes of accidents, and rarely contains any comments that would aid in preventing their recurrence. A few years ago one of the Western mining periodicals, the *Mining Reporter*, published each week a list of the mine accidents that had occurred during the preceding week together with the causes as far as ascertained; but that section of the paper seems to have reached too tender a spot in the anatomy of mining men for it finally was discontinued. The motive of that column was good, for it brought home each week to the men in charge of mines this question of mine accidents; yet it did not arouse any discussion.

Mine accidents do not decrease in number by being ignored, so it seems to me to be high time that some of the time and the space devoted to wild hypotheses in regard to ore formation were given to the humanitarian side of mining and that the study of the causes of mine accidents and of ways of preventing recurrence of similar accidents were undertaken.

During the first two and a half years after I left college, I worked as a miner at many of the important mines in the Western States. While mucking, running machines, single-jacking and timbering, I had a chance to observe mine workings in their every-day condition, as well as in the holiday attire that a stope dons when the superintendent or manager obligingly tells the foreman that he will probably go underground at a certain time. In this article I shall state some observations that I have made upon the causes of different mine accidents, and in some instances I shall try to point out ways of avoiding the recurrence of such accidents. While dis-

cussing accidents in mines I shall also discuss mine fires.

ACCIDENTS FROM OVERWINDING

Few accidents, at least in the United States, result from breaking of the hoisting rope or from overwinding; still I once had the experience of being hoisted within 10 ft. of the sheaves by a drunken engineer. As a rule the hoisting engineers are the most reliable men in a mining camp, and no one should infer from this that drunkenness is common among hoisting engineers. Still it emphasizes the fact that all classes of men must be watched. To guard against this class of accidents it is well to have some device for preventing overwinding, such as those that shut off the power at a certain point.

While speaking of drunkenness it might be well to say that drunkenness is a contributory cause in many accidents, for many times miners go to work in a partially intoxicated condition. By hiding among his fellows, often the miner conceals this condition, but as soon as he goes underground the hot, vitiated air soon increases the stupor. An intoxicated or partly intoxicated miner does not work, and he is a danger to himself and others. In order to guard against a drunken miner's getting underground, all miners, before going on shift, should have to report to the timekeeper in a well-lighted room where for some distance the miners must file past him. Any miner coming to work drunk or even partially intoxicated should be fired. The miners should be double-checked, i.e., they should be checked both when they go on and come off shift. This double checking insures that all the men are out of the mine at the end of the shift. Besides, it shows that all the miners stay underground the full time. At some mines where on night shift the shift boss makes only one round after dinner the miners have been known to sneak home before the end of the shift.

ACCIDENTS IN SHAFTS

The few accidents that happen in the shaft during hoisting are mainly due to the following three causes: Riding on the same deck with timbers; riding on the cage with tools, such as picks, drills, etc., in the hand; and riding in empty, or on top of loaded cars.

Timbers should be securely lashed when lowered in the shaft, and no one should be allowed to ride on the deck with them, even when there is plenty of room, for the timbers often slip in a very mysteri-

ous manner on the wet iron of the cage floor. No one should be allowed to carry tools on the cage, for if the hoisting engineer stops the engine suddenly the men will probably drop the tools with the possibility of their catching between the cage and the timbers. Loose drills should never be lashed on the cage, but a special box, mounted on a low truck with a broad axle base, should be provided in which to lower the steel. If the steel or tools, such as picks, are placed in a box of that kind, the truck is locked on the cage, the tops of the drills are securely lashed, and the tool "nipper" is made to ride on the other deck, no accident will happen when lowering the steel or tools.

GATES ON THE CAGES

Riding on the cage in a car, whether loaded or empty, is extremely dangerous, and many are the deaths that have been caused by it. Fortunately most companies in the United States strictly forbid riding on cars in the shaft, yet at some otherwise well managed mines this is allowed. The danger arises from the fact that the miners are apt to forget to latch the catch that holds the car. The jar of the cage throws the car off, and the men are caught between the cage, the car and the timbers.

Hoisting of the shifts without gates on the cage is another source of accident in shafts. At mines where more than 30 men work on a shift it should be made a criminal offense to hoist or lower the shifts without gates on the cage, for generally the cages at which times are so crowded that if gates are not used men are apt to be pushed off, while being hoisted. The gates do not cost much, and when they are used the men can be hoisted and lowered in less time. The gates should be of the swinging type and not of the folding latticework or pantograph type, for the latter are apt to belly out under pressure and so cause an accident. Overhead bars low enough so that the men can hold onto them easily should be provided on all cages used for hoisting men. These can be arranged so as to swing out of the way when the handling of the men is finished.

At large mines the men often crowd badly at the stations when they are being loaded onto the cages at the end of the shift. This is dangerous; the foreman or the superintendent should see to it that it does not occur. The station tenders, unless backed up by a special order from the foreman, are generally unable to cope with the difficulty. Still, if the station tenders skip the levels where the crowd-

ing occurs, and hoist first from the other levels, the crowding generally ceases.

In hoisting with buckets many accidents result. These happen more frequently from the non-use than from the use of crossheads. The accidents with crossheads are due to their "hanging up" in the shaft and then falling upon the men in the bucket. If the height of the crosshead is two-thirds of its width there will be little danger of its catching between the guides; if one of the several recently designed crossheads is used, such accidents cannot happen, for the bucket is fastened to the crossheads is used, such accidents cannot be not used for sinking, the crosshead should be securely fastened to the hoisting rope as near as possible to the bucket, and if the bucket is designed to dump by rotating in its bale, the bale should be fastened securely to the crosshead. When sinking with a bucket not provided with an improved locking crosshead, a clip should be securely fastened to the hoisting rope far enough above the bucket so that the crosshead could not strike even a 7-ft. man on the rim of the bucket. A little platform on the top of the crosshead, providing room for four men, will do away with the need of riding in the bucket except when shifts are being changed. If at that time the bucket is lashed to the crosshead, such accidents will be prevented. Many deep shafts have been sunk by means of a bucket without using crosshead and guides, but I think that the use of a crosshead and guides should be made compulsory unless the hoisting is done with a windlass. In case the ground stands so well that timbering is not required, rope guides can be used.

ACCIDENTS WITH EXPLOSIVES

In considering accidents due to explosives I will not consider those that result from carelessness in thawing dynamite, for generally the person who blows himself up in that way is one of those who knows it all, and no advice would have aided him. Fortunately, as knowledge regarding dynamite becomes more common, accidents due to carelessness in thawing dynamite are rapidly decreasing in number.

At several mines in the West there have been serious accidents arising from the storage of dynamite in large quantities underground. The correct place for the storage of dynamite is in a short drift driven at some distance from the mine entrance and closed by a thick door covered with a piece of turn-sheet. Several accidents have resulted at mines where the dynamite was stored in a wooden house. In some instances no one had been near the building for some time, and the only explanation suggested was that a stray bullet from some hunter's rifle had exploded the dynamite. In case that owing to flat topography, a drift cannot be driven conveniently, the powder-house should be

made of brick or stone and should have iron-protected doors.

In no case should more than two days' supply of dynamite be taken into the mine, and only one day's supply should be kept on each level. The dynamite on the different levels should be stored in a dry part of the mine (some unused drift is often convenient), and if possible this place should be electric-lighted. No miner should be allowed to carry a lighted candle into the powder room, if it is lighted by electricity, and in no case should anyone be allowed to take a pipe (in fact all smoking should be forbidden in a mine) or capped fuse into the powder room. The caps and fuse should be kept at least 100 ft. away, and the place for the fuse should not be too warm, since some fuse deteriorates rapidly in a warm temperature and, owing to swelling, becomes difficult to cap. The place where the detonators are kept should be tightly floored so that if any are spilled they can be picked up easily; and none will then be lost under foot, possibly later to be exploded, disabling someone.

The carelessness of miners in handling explosives is notorious, but an occasional watching of the men at powder time together with an occasional firing of a mafi caught handling dynamite carelessly will soon result in a greater respect for dynamite.

At many large mines several powder-monkeys are employed. In the morning they keep busy capping fuse, thawing dynamite, and packing it into sacks for the different levels. In the afternoon the powder-monkeys go through the stopes distributing the dynamite and fuse to the men, keeping record of the amount of dynamite and the number of fuse given to each miner. In several mines this has resulted in a large decrease in the bill for explosives. Anyway the method is safer than letting the miners get their own dynamite for explosives are handled mainly by experienced men in whom the company has confidence.

ACCIDENTS CAUSED BY MISSED HOLES

Missed holes are the cause of most of the accidents with explosives. Misfires may occur from many causes, chief among them being improper loading and improper placing of the holes. When holes are drilled too closely together cut-off holes result; if the cap and fuse are torn out of the charge, a missed hole results. More frequently the misfire is caused by improper loading. One would naturally think that miners must know how to load a hole properly, but many do not. In cold stopes a frequent cause of misfire is the placing of the primer in the hole with the fuse end ahead. This necessitates so sharp a bend in the fuse, that frequently the powder train in the fuse is broken; and a misfire results. Among other mistakes in loading is the improper use of tamping. For these reasons the foreman and super-

intendent should investigate the manner of loading used by a miner guilty of frequent missed holes.

All miners should count their holes as they explode, and should report any misfires to the shift-boss. The shift-boss should immediately record these on a blank slip that is left for the boss on the other shift. Before he goes home, the shift-boss should post a copy of this on a bulletin board so placed that the miners when they go on shift cannot help but see it.

When "short a hole" frequently the miners assumed that an unusually loud report was a "double," and do not report a missed hole. Any miner can count, and after spitting the holes he can go to some safe place where he can hear his holes go off; consequently any remissness in reporting holes is carelessness pure and simple. To insure that, in cases of doubt, the miners will report a missed hole, any miner who fails to report a misfire should himself be fired.

Most missed holes occur in development work, and it is just in those places that it is sometimes difficult for a miner to find the missed hole. Consequently all miners working in drifts, crosscuts, raises, winzes and shafts should be made to show by means of arrows on a diagram the position, direction and relative length of all holes blasted. This enables the other shift to find quickly a missed hole. Besides, in case of failure to report the misfire, the miners on the next shift, after looking at the diagram of the holes blasted, would probably recognize the presence of a missed hole. In stopes a miner can generally tell from the shape of the breast whether or not there has been a missed hole; indeed a good miner before he begins work generally tries to figure out how much and where the other shift drilled.

GOVERNMENT INSPECTION OF EXPLOSIVES NEEDED

While discussing explosives and their use, it is well to draw attention to the fact that, while in other countries explosives, detonators and fuse are carefully tested, in the United States any old thing can be used. For instance there is no regularity in the rate of the burning of fuse. In one mine one kind of fuse with a certain rate of burning is used; in another a different kind with a different rate. Miners change frequently from mine to mine; at each change they are apt to use a new kind of fuse. They ask other miners about the speed of the fuse, and cut the fuse accordingly. They may cut it too short, and then they must scamper to get to safety. In Western Australia fuse must burn not faster than 80 sec. per yd. nor slower than 100 sec. per yd. At first this limitation seemed impracticable to some, but according to the Report for 1907 of the Department of Mines, Western Australia, page 221, out of 311 samples of fuse tested in 1907 only 28 did not comply

with the requirements of the State law; 17 samples went over and 11 under the prescribed limits. In regard to detonators, E. A. Mann, chief inspector of explosives, Western Australia, in the July, 1908, issue of the *Monthly Journal* of the Chamber of Mines of Western Australia states that frequently in his tests he has found that the nominal strength of detonators is not rigidly adhered to by manufacturers. He recommends, therefore, the use of only such detonators as experience has shown to be reliable. His statements should be borne in mind for possibly some misfires may be due to poor grade of detonator. It seems to be high time that some action were taken by the United States Government in regard to explosives, detonators and fuse. Anyway the superintendent should have each purchase of fuse tested for speed and regularity of burning before the shipment is accepted. At present too little attention is given to explosives in the United States, especially by mining men.

ACCIDENTS IN STOPES

Men frequently fall down chutes and manways, or are injured by rocks or tools falling down manways. Such accidents in stopes and drifts are needless as they can easily be prevented. In the first place all chutes and manways should start from an offset on the level below, and should "hole" into an offset on the level above. Then timbers can be hoisted or lowered to the stope without blocking the drift, drills slipping out of the chain while being hoisted will land in the offset without tearing up the rails, and rocks falling down the manway will not strike some passing carman on the head or dirty up the track later possibly causing an upset. When the raise and chute "hole" by the side of the track, they should be railed in so that no one can walk into them. A raise should never be driven so as to "hole" into the level under a track, for if it is, sooner or later someone will fall down the raise and be killed.

The tops of all chutes and manways, as well as the bottom of all manways, should be covered with trap doors so that, when the stope is not being worked, the doors can be closed and the air caused to go up through those stopes that are being worked. Moreover, such trap doors are better than the railings for preventing persons or objects from falling down raises or chutes, and as has been shown, greatly aid in properly ventilating the stopes. The timbers in all manways that are in use should be cleaned from time to time in order to guard against accidents from falling rocks when several men are using the manway at the same time.

In the stopes, accidents from falling down chutes or manways can be prevented by means of grizzlies and railings in the case of square-set, and by means of grizzlies and trap doors in the case of stull chutes. The grizzlies also prevent

large "round heads" from being thrown into the chute.

POISONOUS GASES AT METAL MINES

While poisonous gases are more frequently in coal mines, still at a few metal mines there has been trouble with flows of gas from solid rock. This is unusual, but one or two cases have been reported from Colorado and, as I remember, but I may be mistaken, one man was killed by the gas. This gas contained principally carbon dioxide. The death of this man indicates the chances that men will sometimes take in bad air. No man should be allowed to stay long in a place where a candle will not burn. In fact he should not stay at all in such a place; not because it is very dangerous to health if the oxygen is just insufficient to nourish a candle flame, but because after that point is reached the person has no way of telling how much farther the oxygen has been depleted. Still I know of mines in the West where many Italians are working in electric-lighted drifts and stopes, electric-lighted because the air is too poor to support combustion. Such practice is criminal, unless it is absolutely necessary.

Such workings are generally in caved sulphide orebodies, and the depletion of the oxygen is due mainly to the rapid oxidation of the sulphur in the heated particles of finely pulverized sulphide minerals. The heat in these places is due partly to the oxidation and partly to the grinding and crushing of the caved ore. The necessary oxygen can be supplied by opening wide the valve on the air pipe or by using a blower. Generally the compressor is already too small for its work, or what is almost the same thing the shift boss thinks so; consequently the poor miner works in bad air.

Whenever any such places are being worked in the mine, special care should be taken in hoisting from those levels, for these men are very apt to faint when they suddenly encounter the cool, fresh air in the upper part of the shaft. Men who have been working long in a stuffy raise or in a stope in which the powder smoke hangs badly, are also apt to faint while being hoisted. It is especially because of these facts that the gates ought to be used on the cages. Yet I know of one case in which, even when gates were used, a miner upon reaching the cold air fainted, his head protruded beyond the cage, and he was crushed to death. Therefore, owing to that possibility, whenever a miner has a bad powder headache or has been working in bad air, he should be ordered to report the fact to the station tender, who should load him as near the center of the deck as possible so that if he faints his companions can hold him.

In tapping old shaft workings the workmen should be prepared to meet with quantities of carbon dioxide, and, in case the workings contain much timber and

have been under water for some time, the superintendent should not be surprised if, on connecting with those workings, he finds inflammable gases.

MINE FIRES

The subject of gas leads us to that of fire, for most of the carbon dioxide giving trouble at metal mines is due to the burning of timbers. Fires are apt to occur at any time at mines where much timber is used, and even where little timber is used the shaft timbers are liable to catch fire if the shaft is dry. Although fires at metal mines have caused the death of many miners, still, comparatively speaking, few metal miners die in mine fires. Nevertheless, owing to the fact that at most mines little provision is made for fighting or preventing fires I will treat of the subject.

In dry shafts in order to prevent fire a little trickle of water should be allowed to fall on the top sets and flow slowly down the other timbers. Since it is only necessary to keep the timbers moist, the flow of water should not be enough to make the shaft wet. This moisture also prolongs the life of the timbers, for it diminishes the growth of bacteria; especially is this the case in warm, upcast shafts where the bacteria and fungi increase rapidly.

Many lives have been lost at metal mines in trying to rescue men from burning workings. This rescue work can be carried on with little danger if one or two helmets for fighting fires are kept at the mine. Some of the later invented helmets, in which the wearer carries the supply of oxygen along with him, are to be preferred as they are less cumbersome than the older type supplied with air from a hose, yet the homemade Anaconda helmet recently described in the *JOURNAL* by Robert N. Bell is sufficiently good at mines where compressed air is handy. At least two helmets should be kept at mines where much timber is used underground. At a number of mines thousands of dollars, to say nothing of lives, might have been saved if fire-fighting helmets had been at hand in the early stages of the fire.

The compressed-air pipes at all shaft mines should be connected to the surface water-supply so that by opening a valve the air-line can be converted into a water-line. If then several nozzles, so constructed that they will screw into the couplings on the air-drill hose, are kept in the storehouse, the mine is equipped with a good fire-fighting system.

FIREPROOF DOOR NEAR PORTAL OF ALL ADITS

Fires are especially dangerous at mines worked through adits, for generally at such mines there is a strong ventilating current sucking up through the stopes. At mines, where the blacksmith shop and

other buildings are connected with the adit by snow sheds, in case the surface buildings catch fire the smoke is apt to be sucked through the adit up into the stopes. Frequently this smoke suffocates some of the miners before they can escape through the upper workings.

Such accidents happen almost every summer, and yet they are easily prevented by a few precautions. In the first stretch of untimbered ground in the adit an airtight, self-closing door should be hung, which is arranged so that it can be closed from a distance. The door should be held open by a wire or rope running on pulleys to the entrance of the mine. Outside of the mine, in case that a wire is used, a rope must be attached to the wire. The end of the rope should be fastened in the blacksmith shop or at some other place where men are constantly present. Then in case of fire someone can unfasten the rope and let the mine door close. This rope should be carried along near the top of the snow shed so that, in case the shed catches fire and no one unfastens the rope, it will burn, releasing the door. The door being airtight and in an untimbered portion of the mine prevents the sucking of the smoke into the mine workings, no matter how violent the fire may be outside. This door should be frequently tested so as to see that it works easily, and in winter special care should be taken that ice does not form so as to prevent the door from closing airtight.

On each level of all mines in the drifts leading to the shaft stations similar airtight doors should be placed. In case the drifts are timbered, a concrete bulkhead with an iron door should be built. By closing these doors the stopes of each level can be shut off from the shaft in case of fire.

Mine fires may start from the caving of timbered stopes in orebodies rich in sulphur, but most start from the carelessness of the miners. The fire at the Homestake mine, Lead, S. D., started, it is said, from a blast that set fire to some old timbers in a portion of the mine that was being reopened. When such work is being done, not only should the miner be required to go back to the face after blasting, but also the shift-boss or, if there is a "fire bug," the "fire bug" should be specially ordered to visit all such workings. Moreover, when reopening old stopes or drifts in which many old timbers are found, a water pipe should always be carried along as the drift advances.

In square-set mines most fires start in stopes from candle snuffs left on the timbers. The explosion of the holes generally extinguishes these lights, but in some cases it does not. Leaving a lighted candle in a mine is good cause for dis-

charging a miner. If much timber is used, a "fire bug" should go through all the workings, unless sconces are used. Sconces are far better than any "fire bug."

THE SCONCE

The scone is an old Cornish device which is used in the square-set stopes of the Copper Queen Consolidated Mining Company's mines at Bisbee, Ariz., to hold the candles placed at the chutes and at other places in the stopes. It is shown in an accompanying illustration. The scone is made of cast iron, and in order to resist the rough usage that it undergoes it should be made especially strong. The scone used at Bisbee is a one-piece casting consisting of a back and a bottom portion meeting at right angles. The back, which keeps the flame from blowing against the timbers, has a hole in it for hanging the scone from a nail. The lower round part of this hole is large

SCONCE USED AT COPPER QUEEN MINES,
BISBEE, ARIZONA

enough to go over the head of even a 60-penny nail, while the slotted upper portion is wide enough to slip along the body of a nail of this size, but not wide enough for the head of a 40-penny nail to slip through it; this prevents the scone from being knocked off the nail on which it is hung. The hole should be placed at least an inch from the rim for this part of the scone is the weakest. The bottom piece has a rim $\frac{1}{2}$ in. high extending all around it so as to catch the melting grease or paraffin from the burning candle. In the center of the bottom and about 2 in. in front of the back is the candle holder. This is a ring $\frac{1}{2}$ in. high having the diameter of the candle used at the mine; it is slotted so that the miner can easily gouge out, with his candlestick, any butt of a candle remaining in the holding ring.

If this ring holder is kept cleaned out so that the candle is securely held, and the grease is not allowed to accumulate on the bottom, there is no possibility of

the burning candle setting fire to the timbers, for it cannot fall out of the scone. As soon as the miners have been trained so that they will not burn candles in, or on, anything other than their candlesticks, or these sconces, no "fire bug" is required to go through the stopes to guard against fire. Sconces have been used in the Copper Queen mines at Bisbee for years without, I think, a single fire. This speaks well of the scone, and other mining companies using the square-set method should adopt it. A few fire extinguishers are also very useful about the surface plants at mines.

ACCIDENTS CAUSED BY FALLING ROCKS

Finally we come to the main cause of accidents at metal mines, and for that matter at coal mines; that is, falling ground. Accidents from falling ground are of two classes—those due to carelessness, and those that are due to unforeseeable circumstances. In the latter class belong those accidents in which stopes suddenly cave, or large blocks of ground—so large that on testing they sound as if they are solid—fall. These accidents are due to unsuspected slips that cut across the vein. Geological maps, on which the principal movement planes are indicated, aid in preventing such accidents.

The other, the careless class of accidents—those accidents that the mine inspector and the coroner's jury generally report as unavoidable and due to no contributory negligence on the part of the company—claims the most victims. All accidents due to the falling of slabs of rock weighing less than a ton are due to carelessness; most people say due to the carelessness of the miner; certainly, but also due in most cases, I claim, to the contributory negligence of the company. In Mexico the men in charge of the mines realize that they must watch the miners so as to safeguard them (besides the Mexican government investigates the methods used at mines where accidents are too frequent); but in the United States, mining men assume that the miners know enough to safeguard themselves. Such an assumption, I assert, is the cause of half the accidents at metal mines.

Men accustomed to danger become careless. It is not because the miner in the United States has insufficient brains that he requires watching, but it is because in time almost every miner develops a contempt for small dangers such as the falling of a small rock from the roof. He becomes lazy, and rather than take a little time to make the place safer he begins work after picking down the worst of the roof.

You can depend upon the machinemen's picking down the back immediately surrounding the place where they are going to set up the drill, but, since picking down the back takes time and is hard work, they generally skim over the rest of the roof near the face. In case the mucker is a

¹In Western mining camps the name "fire bug" is applied to the man who goes through the stopes after the shift leaves the mine to see that no fire, such as a burning candle snuff, etc., is left in the mine.

fellow countryman the machinemens will be more careful, but if he is of some other nationality the miners will soon call out that the back is all right. During the last few years most of the mucking in the West has been and for that matter is still done by those nationalities that the Western miners call "dagoes"—not necessarily Italians, but also Hungarians, Poles, Finns, Austrians, Montenegrins, Servians, etc. These fellows are generally stronger in the muscles than in the head, so they begin to muck whenever they are told by the miners (in the main, Irishmen, Cornishmen or their American-born descendants) that it is safe to do so.

When the shift-boss comes along he first looks at the muck pile that the other shift has left for him, then he notices what kind of a set-up his miners are going to have, and finally he looks to see if any timbers are needed. Then he hurries along probably with some admonition to the muckers to "sail in" and get him out some "muck." The foreman comes along soon after, and his trip is even faster than that of the shift-boss, for he must cover the whole mine and must spend time keeping up his reports and letting miners "rustle" him for a job. Neither the shift-boss nor the foreman pays especial attention to the condition of the roof.

The mucker mucks on, finally a slab, jarred loose by the blows of the machine drill, falls and hits him. He is hurt, possibly killed. Whose fault? The coroner's jury will say that it was due to his own carelessness, but I say that it was due to his own ignorance, the laziness of the miner, and the want of care on the part of the company's agents, the shift-boss and the foreman.

The majority of the readers of this will probably say that I exaggerate, but I can judge only from my own observations for I know of no others who have contributed theirs. During the two and a half years that I worked as a miner, and it was mostly at the better mines of the West, I can remember (and of this I am almost positive) only two occasions when I saw or heard of any miner's being "called down" for not picking down the back. Both those times it was myself who was "called down." Once when I was mucking in the Camp Bird mine, Colorado, the shift-boss "jacked me up" because I, greenhorn that I was, was shoveling under some slabby ground. He ordered me to take the ground down, but to the miner whose duty it was to keep the stope safe he said not a word. Another time in another mine I was deservedly "called down" for beginning to drill before I had picked the face of the drift clean of loose rock.

EVENTS LEADING UP TO AN ACCIDENT

I have timbered in several places where my partner and I would not stand a stick of timber before we had picked down the back; but the muckers had been working under the ground for some time. They

did not know better; we did, or at least my partner did. I well remember picking down over a ton of rock from a roof under which muckers had been working for two shifts, and even then my partner and I would not stand the timbers while the air drill was running. These occurrences were in well-known mines of the West that were in other respects very well managed; such occurrences were not unusual.

The cycle of events leading up to accidents from falling ground is a long one, but almost universally it is somewhat as I will describe it. The manager asks the superintendent for tonnage; the superintendent demands ore from the foreman; the foreman tells the shift-boss to get out the rock; and the poor shift-boss goes through the stopes yelling to the machinemens and the muckers, "Rock! Rock! Rock!" Consequently the shift-boss looks upon the timbermen as a nuisance who block the tracks and the stations with their timbers, thus decreasing the tonnage; and the stope—well, as long as it does not cave, the shift-boss inwardly says: "The stope be dammed." His first anxiety is to see the pile of rock that the other shift has left for him; his main activity is watching the chutes from the different stopes and the tally-boards at the different stations.

The machinemens notice this, and they see that neither the shift-boss nor the foreman watches the roof. Consequently the time that they spend in thoroughly picking down the back is not considered, and, as they probably have a family depending upon them and therefore desire to hold their jobs, they have to work harder the remainder of the shift in order to get in their round of holes and make a "showing." The miners begin to slight the back of the stope; nothing is said. They get bolder, they skim over the back and only pick down where they are going to set up the machine, and still nothing is said by the bosses. An occasional small rock falls on a shoveler's back. The poor foreigner frightened runs back, then swears in broken English at the miners. Unfortunately that is all that he does; if he only hammered the miners over the head with a shovel, he might save his own head later. As it is, a few punches at the roof with the pinch bar suffices to reassure the shoveler; then the miners begin drilling again. Everything goes lovely in this manner for days until finally a rock falls from the roof and someone is hurt or killed. Then for a few weeks the miners are more careful, but soon they, the shift-boss, and the foreman are back again in the old lazy, careless ways.

CONCLUSION

Consequently I say that, unless the superintendent sees that the foreman sees that the shift-bosses see that the miners pick down the back, the miners will only skim over the roof and will not pick it down properly. Until the miners are

made to pick down the roof properly, falling ground will continue to be the cause of most mining accidents.

I hope that possibly these notes may induce some companies to begin the study of this problem of preventing mine accidents, and that they may serve to make life less hazardous for the miner—especially for those partners who patiently endured me while I was trying to learn to mine. In conclusion I ask those readers who are in charge of mines to take a trip through the stopes so as to observe in their own mines the condition of the roof at the different faces, the position of the raises, the amount of rock on the timbers in raises, winzes and shafts; then I hope that they also will discuss this question of accidents. The number of accidents at mines can only be diminished by studying their causes and by improving some system to prevent their recurrence. This can best be accomplished by each telling the other what he has learned about mine accidents, and by suggesting to one another ways of preventing similar occurrences. Finally—let me whisper it for no one will pay attention to the suggestion if it is shouted—possibly, if the miners learn that the men in charge of mines are taking a vital interest in their (the miners') safety underground, labor troubles may be less frequent than in the past.

Drawback on Zinc Shavings

SPECIAL CORRESPONDENCE

In accord with a decision rendered by the division of customs in the Treasury Department, a drawback of the amount of duties levied, less 1 per cent., will be allowed in future upon the exportation of zinc shavings manufactured from imported zinc in sheets. The drawback entry is required to show the total quantity of zinc shavings exported, the quantity of imported sheet zinc used in the manufacture, the quantities of the different kinds of waste and the market value thereof, together with the value of the imported zinc at the factory. It must also show that the shavings were manufactured of the material and in the manner set forth in the sworn statement of the exporter. In liquidation the quantity of the imported material which may be taken as the basis for the allowance of the drawback may equal that claimed in the entry, after official verification of exported quantities, provided it shall not exceed the net weight of the exported shavings with the proper quantity added there to compensate for worthless waste. In estimating this waste the value of the scrap is to be duly considered.

All drifts where much tramming is done should be well lighted.

Early Systems of Mining the George's Creek Coal Secured About 50 Per Cent. of the Seam, Present Methods Insure Recovery of 95 Per Cent.

B Y H. V. H E S S E*

*Mining engineer, Frostburg, Md.

a poorly developed mine has been the greatest factor in encouraging careless methods of recovering coal both from rooms and pillars, and it is no exaggeration to state that the abandoning of many acres of good coal, which could have been recovered by more thorough and known methods, can be traced directly to this cause.

THE PROPERTY SHOULD FIRST BE CAREFULLY EXPLORED

In the development of a coal property after a reconnaissance has been made, a reasonably thorough knowledge of the seams to be exploited should be attained before the installation of a permanent plant. This can be done by diamond drill-

wasted in unnecessary litigation due to encroachments and violation of mining rights. The main haulways of more than one mine have been driven far into another man's property, because of inaccurate maps and surveys. Accurate surveys of the surface features of a property have a direct and important bearing on the inside workings in other ways, such as showing the relative position of two or more mines in the same property, the proper location of bore holes or shafts for drainage and ventilation purposes and the determination of thickness and nature of strata overlying the seams under development. Armed thus with a general knowledge of mining rights, thickness, continuity and quality of coal, dip of the

favorable to haulage, drainage and ventilation in the mine could be obtained.

After the location of the new plant has been selected and the drift, slope or shaft opening completed, it must then be determined what general method of mining will be adopted; that is, whether the seam is to be worked longwall, or by pillar-and-chamber. The former is especially adapted to deep mines where the great weight of the superincumbent strata makes the pillar method impracticable, or to thin, flat seams with a brittle top under shallow cover as is found in the central Western States. The general conditions encountered thus far in the Appalachian field are probably more favorable to the pillar-and-chamber or one of its many

FIG. 2. METHOD OF WORKING GEORGE'S CREEK "BIG VEIN" SEAM IN 1850

ing, numerous crop openings, or a pair of headings driven through the property at some favorable location. The coal from such headings could be disposed of locally, shipped from a temporary dump, or, in the absence of railroad facilities, stocked until disposition could be arranged later.

While this is going on, a competent surveying party should be engaged in accurately locating the boundaries, principal streams, etc. If the property is large and the topography favorable, a triangulation survey can be made and all boundary lines carefully tied in. The mining rights in the original grants should be thoroughly studied in this connection and complete records made. Too much stress cannot be laid on the necessity for an accurate survey. Much money has been

measures, probable roof and floor conditions and the thickness and nature of overlying strata, the struggle for maximum recovery is well begun.

SELECTION OF PERMANENT SITES

After this preliminary reconnaissance has been completed and some idea of the boundaries of the property has been obtained, the selection of the sites for permanent plants is in order. The spot offering the most favorable outside features for cheap instalment of a plant is often the one accepted, whereas by selecting one with less favorable surface conditions, which, by the reasonable additional expenditure of money, could be molded satisfactorily, the best conditions

modifications than to the longwall method of mining.

After the general method has been selected, the main headings should be commenced and driven in a direction favorable to haulage and drainage. Much money has been spent in operating properties where these two factors did not receive careful attention in the beginning. Where the seam is of uniform thickness and the dip of the measures regular, economic haulage and drainage is a comparatively simple problem, but where the measures are of a rolling nature, it may become a standing menace to cheap production. Furthermore, the employment of improper drainage methods has resulted in the abandoning of large areas and the loss of much coal in pillars. Since

main haulways and airways should be free from all interference, a traveling-way for men and animals should also be provided and therefore not less than three parallel headings should be driven for the main entries.

at the lowest cost of production, and with the greatest degree of safety to the men. Whatever method is selected, be it pillar-and-chamber with its wide rooms, pillar-and-stall with its narrow rooms, or the panel system, the great and important

terminated by what judgment and experience dictate, after a careful study of the nature of the superincumbent strata. It is not intended to ignore empirical rules based on actual observation of the effect on certain stratification by the removal

FIG. 3. METHOD OF WORKING GEORGE'S CREEK "BIG VEIN" SEAM IN 1870

FIG. 4. METHOD OF WORKING GEORGE'S CREEK "BIG VEIN" SEAM IN 1890

SELECTING THE METHOD OF OPERATION
In determining the method of extraction to be adopted, the engineer, after a careful analysis of the data obtainable, should be careful to select that system which will effect a maximum recovery of coal in the best condition for the market,

factor to be considered is the size of the pillars to be left in first working. Although the limit of subsidence varies with the height of the excavation, there has never been established a uniform ratio between the two, and as a consequence, the size of pillars must be principally de-

termined by what judgment and experience dictate, after a careful study of the nature of the superincumbent strata. It is not intended to ignore empirical rules based on actual observation of the effect on certain stratification by the removal

for intelligently determining the size of the pillars to support haulways and working places.

THE SIZE OF PILLARS

The size of pillars to be left in a mine

edge or foresight in this respect. There are cases on record where not only the pillars supporting the working places were too small, but those supporting main haulways, shafts and slopes as well, and a "squeeze" starting over the working places

pillars are depth, thickness and structure of the seam and the inclination and nature of the overlying and underlying strata. Other factors which have a bearing on this subject, because they modify the detail method of working to be

FIG. 5. METHOD OF WORKING GEORGE'S CREEK "BIG VEIN" SEAM IN 1900

FIG. 6. METHOD OF WORKING GEORGE'S CREEK "BIG VEIN" SEAM IN 1904

forms a question about which there are widely divergent opinions among mining men, and too much thought cannot be given to this important subject. Many thousand tons of coal lie buried and abandoned as lost beneath "creeps" and "squeezes" resulting from a lack of knowl-

in one section of the mine has extended over the main entries, closed the shaft or slope and the whole mine has consequently been abandoned. It is better, therefore, to lay out the pillars too large rather than too small.

The principal points affecting size of

adopted, are the ventilation required and the tonnage desired from each district.

Pillars should not be left standing, but taken out as soon as possible after rooms have been driven. The percentage of coal won in the first working should not be too great, because it increases the cost of re-

These pillars were also of insufficient size, robbing was conducted spasmodically and although more coal was recovered than in the adjoining districts, a large quantity was lost. In addition to the small pillars, the method of robbing them was calculated to promote "squeezes." It appears to have been the method to hold the strata with props until sufficient coal had been removed to enable the weight to break the props. As a general rule, however, before this was attained, the weight had induced a "creep" which is well known to have no limits within a territory of small pillars.

METHOD USED IN 1890

Fig. 4 represents a method in use in 1890. The main entries were driven from the slope on the strike of the seam, sufficient grade being allowed for drainage. Cross-headings were driven on an angle of about 35 deg. to the main entry and headings were turned off these parallel to the main entry. Rooms were turned, as shown, from all headings on 100-ft. centers, and pillars were split by half-rooms

to 2½ per cent. in favor of the loads. From these haulways cross-headings are deflected at intervals of 240 ft. at an angle of about 25 deg., and driven on a grade of 4 to 7 per cent. Rooms varying in length from 100 to 800 ft. are turned on the rise of the coal from these cross-headings. The rooms are driven 15 ft. wide on 65-ft. centers, leaving pillars 50 ft. wide. Twenty-five rooms are driven in each of these diagonal panels. Unusually large protecting pillars are left along the main haulage-roads. This system has been found to be especially adapted to rapid gathering of cars, thus insuring a large tonnage.

It has been found, however, that a very large recovery from the pillars is impossible, owing to the many sharp angles, which, in a thick seam of soft coal, are always difficult and oftentimes impossible to extract. This sharp-angle method was even resorted to formerly in cross-cutting the pillars preparatory to drawing them, but this has been changed to a rectangular method, thereby increasing the actual percentage of pillar coal recovered, from 80

length of a panel is about 2500 ft., and contains 22 rooms.

There are five such panels in this district, and when completed, it is proposed to draw the pillars in a retreating fashion with the line of pillar work on an angle of 45 deg. across the whole district. A similar method in another district, but with rooms on a deflection of 35 deg. from a right angle, is yielding 88½ per cent. from the pillars with a total recovery of 94 per cent. from headings, rooms and pillars, and it is believed that this can at least be duplicated if not exceeded in the case of Fig. 6. The maximum dip in this district is 6½ per cent. and the greatest height of the overlying strata 250 feet.

A SUGGESTED PANEL METHOD

With this resumé of systems used at different periods under conditions now known, a suggested method of extracting the coal from thick soft seams with a brittle top and a height of superincumbent strata of 400 ft. or less is presented in Fig. 7. The general designs of the mine for haulage, drainage and ventilation are not given, because they are variable quantities, depending on conditions which change with the locality, and the method suggested is, therefore, limited to the ultimate recovery of the coal.

By this method a territory under development is divided up into rectangular panels of ten rooms each. The room headings are driven on easy grades favorable to drainage and haulage and the panels are worked in pairs. When the upper heading has been driven to its end, the rooms are turned at intervals of 100 ft. with the drawing of pillars following by the retreating method. The rooms are 400 ft. long and 13 ft. wide, leaving pillars 87 ft. in width. The rooms in the upper panel are limited by a barrier pillar separating them from the heading above and those on the lower panel are driven through to the "gob" of the upper panel. The line of pillar work extending over the two panels should have an angle of about 45 deg. The length of rooms can be varied to suit the conditions, and when the height of the overlying measures exceeds 400 ft., the thickness of pillars should be increased accordingly.

Fig. No. 8 shows the method of drawing the pillars in detail. The rectangular method should be carefully adhered to and all sharp angles avoided.

When the work commences, a cut is made separating a block of coal 30 ft. wide and 87 ft. long. This piece is further subdivided into blocks varying from 6x12 ft. to 15x12 ft. in size, which are cut off and extracted successively, as shown. In no case should the small blocks cut off exceed in size the distance a man can shovel under average conditions, which is about 15 ft. The largest of the small blocks should be removed last because it is there that the greatest

FIG. 8. SUGGESTED METHOD OF EXTRACTING COAL FROM SOFT, THICK SEAMS, WITH BRITTLE ROOF

The length of rooms varied from 300 to 600 ft., and they were 13 ft. wide, leaving pillars 36 ft. wide. These pillars were not strong enough to support the overlying strata 500 ft. high, and the usual "creep" resulted when pillar drawing commenced.

This half-room method has the advantage of facilitating gathering of coal and doubling the support of the haulway. The "squeeze" in this district could have been prevented by turning the rooms from the haulway on 200-ft. centers, and, after driving the half-rooms, the resultant pillars would be 85 ft. wide. While this would have avoided a "squeeze," the great weight to be supported by this pillar of soft coal would not have permitted a very high percentage of recovery.

Fig. 5 shows a method adopted in 1900. The maximum dip is 15 per cent., and the greatest thickness of superincumbent strata 425 ft. The slope, together with a parallel air course and manway, is sunk on the heaviest dip of the coal, and double entries are turned off to right and left at intervals of 1000 ft. on a grade of 1½

to 83 per cent. The distance of rooms apart has also been increased in the last few years to 100-ft. centers giving pillars 85 ft. thick. It is expected that the extraction of these latter will show a further increase in the percentage of yield from pillars. The present yield from headings, rooms and pillars under this system is about 90 per cent., considering the recovery from headings and rooms as 100 per cent.

NEW METHOD ADOPTED IN 1904

Fig. No. 6 illustrates a method instituted in the latter part of 1904. The main haulway is an extension of the slope from the opposite side of the basin. Double entries are turned off from this entry on a 1½ per cent. grade 400 ft. apart, from which rooms are driven directly on the rise of the coal. Rooms are from 13 to 15 ft. wide and practically no barrier pillar is left between the room face and the air course of the panel above. They are driven at 100-ft. intervals, leaving a pillar 85 ft. wide. The

pressure manifests itself in the removal of the original block cut from the pillar. When this block has been removed, another cut is made and the process repeated.

The line of "gob" will be approximately on an angle of 45 deg. If it is found impossible to take out the small blocks clean, on account of the "gob" from the preceding work running in on the new cut, a row of props can be set on the upper side of the large block to hold the "gob" when the small blocks below are removed. This method of working should result in a total average recovery of fully 95 per cent. of the seam from headings, rooms and pillars and insure the workings against "creeps and squeezes."

The Tennessee Copper Company in 1908

By B. BRITTON GOTTSBERGER*

The year 1908 was for the Ducktown copper district a busy one, in marked contrast with that of most of the copper-mining centers of the country. The Tennessee Copper Company mined during the year 501,000 tons, and smelted 476,000 tons of ore. The copper production will amount to approximately 14,500,000 pounds.

The labor situation which has, on account of the isolated location of the mines, always been a serious one, was much relieved by the general business depression, and while the actual number of men employed did not much exceed that of 1907, a great increase in efficiency was obtained, resulting in increased output and a material reduction in working costs.

The decrease in the price of copper prevented making any but the most necessary additions to the plant, but the development of the mines was actively pushed. The shaft at the Burra Burra mine was sunk to the seventh level and the drifts on the third level, which had been in progress for some time, were completed; so that the orebody is now opened up on that level for its entire length, a distance of more than 2000 ft. Diamond drilling in the new ground developed a large orebody in the north end of the mine.

At the Polk county mine an additional level was opened and a considerable body of ore of good grade was exposed and will soon be ready for stoping.

STEAM SHOVEL UNDERGROUND

An item of interest, as regards the mine work was the trial of the method of load-

ing ore in the stopes by means of a special shovel furnished by the Bucyrus company. The shovel operated by compressed air worked smoothly, no difficulty being experienced in handling ore which had been broken to a reasonable size. Its use was, however, not found to be an advantage, since it was difficult to obtain a sufficient tonnage in one stope to meet the capacity of the shovel.

In attempting to do this large blasts were necessary, and great difficulty was experienced in breaking large pieces of ore, after the blast, to a proper size for handling by the shovel and later by the crusher. The shovel itself would easily handle any pieces small enough to pass through the dipper, which was of 1¼ cu.yd. capacity; but after hoisting to the surface many of the lumps proved too large for the 18x36-in. Blake crusher, and hoisting was often interrupted on this account. These difficulties were mainly due to the small space available for working the shovel, the face of the stope being about 80 ft. wide. The shovel has been transferred to the company's quartz quarry where flux for the smelter is obtained, and at this point it is doing excellent work.

SMELTING

At the smelter no special change in methods of operation occurred, the most important fact developed during the year being that while the production in one operation of a matte of converter grade (30 per cent. or more) is quite feasible and in fact was made for one month on practically all the furnaces, the copper losses by this method were larger than the loss by smelting in two operations. It is hardly likely that any further attempts along this line will be made.

The adoption on the blast furnaces of a slotted tuyere 12 in. long by 4 in. wide, in place of two tuyeres 3¼ in. in diameter each, proved a decided success, remedying the defect of too small tuyere area in the original design. The furnace equipped with these new jackets handled a much larger tonnage than the others, and the new tuyere will be adopted on all the furnaces.

When the smelter was built the method of conveying air to the blast furnaces was by independent blast pipes from each engine to the various furnaces. On account of changes to the furnaces this system was abandoned; all engines now deliver air to one large air main from which connections are made to the different furnaces. No change in the operation of the furnaces was noted with the new arrangement, and its flexibility will be a decided advantage in operating the furnaces for the production of gas for the acid plant, removing all danger of the blast's being cut on the furnace from failure of the engine.

SULPHURIC-ACID PLANT

The development of greatest interest was that of the sulphuric-acid plant. The year was largely spent in gaining experience as to the proper method of correlating the work of the smelter and the acid plant and solving the many problems which naturally arise in so novel an undertaking. It was found that a radical change in the construction of the furnace tops was necessary, and that special care must be taken at all points to prevent the dilution of the gases by means of false air. After some preliminary attempts a comprehensive plan was devised, and is now being executed, which will completely solve the question of converting the sulphur fumes into commercial sulphuric acid on a profitable basis, rendering available the sulphur hitherto wasted, but now considered a constituent of the ore no less valuable than the copper. The development of the plant will undoubtedly control the fumes to such an extent that the troublesome question of damage to vegetation, which has so long been a matter of dispute, will be eliminated.

The Question of Expert Evidence

The New York State Bar Association has been considering reform in legal procedure, especially with respect to expert evidence. While its deliberations have pertained particularly to medical testimony, practically the same things may be said as to engineering evidence and consequently we deem the matter to be of interest to our readers.

Protesting against "the commercializing of scientific knowledge," which "lessens its accuracy and value," the report of the committee of the Bar Association makes a plea for the insuring of such conditions that expert witnesses, without regard to anything but justice and truth, may give their testimony without bias and without being subjected to improper and contemptuous cross-examinations, misrepresentations and other things tending to create an atmosphere in which the scientific mind cannot be expected to reason calmly and logically.

The committee's report, which was adopted, included a proposed statute as a beginning of the desired reform. It provides briefly that justices of the appellate division shall designate at least 10 and not more than 60 physicians in each judicial district, who may be called as medical expert witnesses by the trial court or by any party to a civil or criminal action; when so called they shall testify and be subject, like other witnesses, to examination and cross-examination. They shall be paid out of the county funds on the order of the trial judge, who shall also decide the amount of the fee. The report in part follows:

*General manager, Tennessee Copper Company, Copperhill, Tenn.

"It is apparent to all that theoretically an expert is the scientist interested solely in facts who should retain freedom of judgment and liberty of speech and should be free from the embarrassment of any personal relations to or with the parties to an action; that he should have no client to serve and no partisan interest nor opinions to vindicate; that he should give his opinion as the advocate neither of another nor himself; that when he speaks he should do so judiciously as the representative of the special branch of science which he invokes, governed by the opinion of the great body of scientists in this relation and in accordance with their most recent investigations.

"That no one should be permitted to distort, pervert or misrepresent his testimony; that when this is done and not until it is done shall we have expert testimony rescued from the disrepute into which it has fallen and thus elevated to its true position as the expression of the particular science for which it speaks; that by the adoption of some such system the mature judgment of the best minds could be obtained and the superficial opinions of quacks and mountebanks would not be thrust upon the jury to their confusion and the hindrance of justice; that such scientific openmindedness is almost impossible where the expert entirely depends for his emolument upon the good graces of contending parties and largely is without the recognition and protection of the court.

"That the commercializing of scientific knowledge under the existing conditions lessens its accuracy and value. That the enormous modern development of special knowledge makes doubt and controversy among experts hired to create it inevitable and aggravates the evils of private expert hire, unscrupulous so-called experts finding it easy to lease themselves and their opinions to aggrieved and aggressive parties who may profit either fairly or unfairly by the technicalities and doubts which they are able to inject into the case in full consciousness that no rebuke will be administered by the tribunal before which their testimony is given; that, therefore, the gravest abuses, not to say scandals, in the introduction of expert testimony have arisen until it has come commonly to be believed that such witnesses are so biased if not corrupt that hardly any weight should be given to their opinions.

During the last 20 years, since the introduction of deep wells in Burma, the petroleum output has grown to about 138,000,000 gal. per year ("Sketch of the Mineral Resources of India"). This has reduced the import in 10 years from 87,000,000 to 62,000,000 gal. even with the constantly increasing consumption. The export of paraffin wax has meanwhile steadily grown.

Refusal to Adjust Prices, a Menace to Prosperity

Elliott C. McDougal, president of the Bank of Buffalo and the newly elected president of the Buffalo Chamber of Commerce, made the following remarks at the annual banquet of the latter organization:

"Never after any previous panic within the recollection of living men have the underlying conditions necessary for the resumption of prosperity been so universally encouraging. After no previous panic have railroads been in so strong a position. After no previous panic have farmers been so prosperous. After no previous panic have we had what we have today—a business public with its material resources, its confidence and its mental vigor unimpaired, ready boldly to take advantage of business opportunities.

"With the exception of the tariff agitation, there is only one small cloud in the sky, and as yet it is only of the size of a man's hand. I refer to the present tendency to maintain, and in many cases to increase, prices. A dealer in leather belting told me the other day that prices had recently risen 15 per cent. I have read that the printers expect to raise prices in the near future. Lumbermen say that they expect that prices of lumber will rise. Many other industries take the same position. The largest industrial corporation in this country—the United States Steel Corporation—is officered by men of ability; men whom an ordinary man hesitates to criticize, but there can be no reasonable doubt that the present policy of the United States Steel Corporation and its attitude with regard to the maintenance of prices is in danger of administering a very severe check to business. I am not competent to argue with a lumber dealer concerning a business about which I know nothing, and about which he knows everything. I am not competent to argue technically with a printer or with a leather dealer, or with the officers of the United States Steel Corporation, but I know that the average scale of prices must come down; that we will have no lasting return toward prosperity until it does come down. If we do not make prices to encourage business we may have no business. We are facing a period of forced economies and of smaller profits. Out of this period will come increased efficiency and new prosperity. The sooner these facts are recognized and acted upon by business men, the sooner will we get started on the road to permanent recovery."

On the same line the Pittsburg correspondent of *The Evening Post* writes under date of Jan. 29, especially with respect to the Steel Corporation:

"Why should the progressive improvement of the last months of 1904 not have been repeated in 1908? One answer is very frequently heard nowadays in Pitts-

burg. Between the beginning of trade reaction in July, 1903, and the middle of 1904, steel prices had been severely readjusted; there was, therefore, even ignoring the question whether or not the consuming community was less hard hit than it is today, a strong incentive for buyers to come at once into the market. The Steel Corporation offers no such incentive today. Both labor and materials had been reduced in the reaction of 1903, whereas, with minor exceptions, wages have this past year remained at the high level of the boom period, for skilled labor at any rate, and there has been organized effort to sustain an artificial price level for finished and semi-finished products. It is true that a number of reductions were officially made last June, but they were very slight, and it is the practically unanimous opinion among representative trade authorities that recuperation has been retarded by seeking to maintain a selling level far above the ideas of the general consumer.

"As matters stand today, price cutting has been freely admitted for some time; it is now openly stated here that the Bethlehem, Lackawanna, and Inland Steel companies have taken a hand in it, that even the Jones & Laughlin Steel Company has been making concessions recently. In other words, producers are taking the business offering below established prices. This is believed to apply chiefly to plates, shapes, tubing, and sheets. It has, however, been stated that the Steel Corporation will not meet the cuts, but it is not stated that official reductions are not likely.

"There are steel manufacturers who defend the attempt to keep prices at a reasonable level because of the high prices prevailing in other industries. The quotations on wheat, corn, and oats, on live stock, lumber, leather, brick, plate glass, textiles, etc., are all referred to in justification. But this does not help the matter with consumers. If the tariff is reduced as it now appears it will be, a wage reduction is predicted.

"Meanwhile Pittsburg expects an indifferent market for iron and steel and is still looking for the reduction in prices which it is contended is necessary to revive business. At the same time, it is admitted that never before have farmers been so prosperous, the railroads in so high a state of efficiency, and the signs of real prosperity so abundant in the first year after a serious panic."

Blanketing having a special texture similar to that of the ordinary military rug is used (*Journ., Chem., Met. and Min. Soc. of South Africa, Nov., 1908*) on the blanket tables at the Giant mine, Rhodesia. The slime from the blanket tables is then treated on canvas tables covered with best fine white duck canvas.

The Goldfield Consolidated Sampling Mill

BY JOHN A. CHURCH*

All of the sampling mills that have been illustrated in the JOURNAL, work on a quantity of ore that is only a part of the mine's daily output, or of a purchased lot,

and the first cut, which may be either 5 or 10 per cent., corresponds to the whole quantity received by mills of the other sort. No handwork and no operation of human agency affects the result which is produced entirely by automatic machines, down to the usual coning floor. Many details of this mill were given in the *JOURNAL* of Sept. 5, 1908. The construction is shown in the accompanying illustrations.

will be 175 to 200 ft. per minute. The cut will be 5 per cent. with one scoop, or 10 per cent. with two. The reject falls to a belt conveyer which moves directly under the sampler and runs to the stamp mill bins.

The first cut falls four or five feet to Gates 26x15-in. rolls running at 97 r.p.m. and is reduced to $\frac{3}{8}$ in. The rolls are directly over and about 3 ft. above a No.

SAMPLING MILL, GOLDFIELD CONSOLIDATED MINES COMPANY, GOLDFIELD, NEVADA

a fifth or a tenth, and this portion has been obtained usually by taking every fifth or tenth car or bucket of ore. The Goldfield Consolidated mill operates on a different system and one that is interesting and important from the fact that it is likely to be the system of the future. All the ore goes through the sampling mill,

The ore is crushed outside the mill and screened in a revolving trommel with 1½-in. perforations which gives a ring size of 1¼ in. All oversize is returned to the crusher and the screened product goes to the mill *via* a 26-in. belt conveyor. It falls into a small hopper which feeds a No. 3 Vezin sampler of 48 in. diameter in the sampling circle, taken at the center of the stream. The velocity in this circle

2 Vezin, which has a sampling diameter of 38 in. and will have the same speed per minute. Here again the cut is either 5 or 10 per cent.

NOVEL FEATURES

The second cut falls into a small bin holding 6 tons or 1 per cent. of the day's supply. It is fed by a shaking spout to a No. 1 Vezin with sampling diameter of 27

*Mining engineer, 15 William street, New York.

in, and the same speed as the others. It will cut out 5 per cent., and the cut falls upon a shaking feeder which delivers to a sample grinder where it is ground and halved. It is further ground and halved in two other sample grinders so the final sample amounts to 75 lb. or $\frac{1}{4}$ lb. per ton of supply.

This mill is noticeable for the fact that there is only one recrushing and two samplings before the sample grinders are reached, for the first cut takes the place of work that usually is done outside the mill. This can be done at Goldfield because of the fineness to which the ore is crushed for the stamps.

The ore supply will be 600 tons in 8 hours or 75 tons per hour. The first sampler receives 42 lb. per sec. or nearly 156 lb. per revolution. The second sampler (if the first cut is 10 per cent.) will receive 4.2 lb. per second and (at 20 r.p.m.) 12.6 lb. per revolution. The third sampler will run on a solid stream, being fed from a bin.

It will be noticed that the feed spout to the first sampler is placed so that the scoop cuts from front to back of the ore stream instead of from side to side as is usual. The stream is probably less thick than wide and the edge of the scoop will pass across the thickness in shorter time than when it has to pass across a spout 12 in. wide. This will shorten the time of imperfect, or selective, sampling and lengthen the time of perfect work.

In examining the designs of various mills I have noticed that some scoops cut the ore stream from side to side, others from front to back and others from back to front. In no case was this variation due to intention. Always it was merely an accident of construction, some beam preventing the convenient placing of the spout so as to obtain the usual side to side cut and causing an installation that gave one of the others and which one seems to depend entirely upon which way the motor happens to turn round. I think there is a choice between these ways of cutting and that the cut from back to front of the stream has advantages over the others.

A bucket elevator with 51-ft. centers lifts all rejects, after the first cut, to the mill bin conveyor.

Courtland, Arizona, a New Copper Camp

By H. W. CHITTENDEN*

The new copper camp of Courtland, which is now attracting much attention in the southwest, is situated in the central part of Cochise county, 35 miles north of Bisbee, and nine miles south of Pearce,

a silver camp on a branch of the Southern Pacific railroad. For several years a little prospecting work was done near the surface, and a little ore was shipped by wagons to Pearce from this district, formerly called the Turquoise district. But only with the recent advent of the Calumet & Arizona and Copper Queen companies into the camp, and the development of large orebodies on the property of the Great Western Copper Company, has the district assumed any considerable importance.

The rock series at Courtland consist of quartzite, probably Cambrian in age, overlaid by limestone that probably includes ages from the Cambrian to the Upper Carboniferous. The total thickness of the limestone does not appear to be more than 2000 ft. The whole series has been tilted to a fairly uniform, steep northeast dip, and many large faults have broken the formation into rather small fault-blocks, duplicating the sedimentary series and greatly increasing its apparent thickness.

Into these sedimentary rocks, have been intruded two igneous rocks, a rather coarse-grained diorite porphyry, and a quartz porphyry that varies in texture from very fine to fairly coarse grain. The diorite porphyry varies greatly, in places being almost entirely free from quartz, and in others containing many large quartz crystals. There have probably been several distinct intrusions of diorite porphyry. The age relation between the two igneous rocks has not yet been definitely determined, since the two come in contact in very few places, and the contacts are for the most part covered with talus.

THE OREBODIES

The ore in the district occurs along zones of fracture in the limestone and quartzite, replacing the rock between the fractures. In all places so far discovered the ore has been closely associated with one or both porphyries, and probably both have been instrumental in the formation of the ore.

The primary ore, as shown in the deeper workings in the western part of the camp, is a mixture of iron and copper sulphides in a silicious gangue usually* resulting from the alteration of limestone. Except for small rich streaks, the primary ore has been of very low grade. Secondary alteration, however, has resulted in great enrichment and in the eastern part of the camp the bottom of the enriched ore has not yet been reached. The secondary ore consists of malachite, azurite, cuprite, and other oxidized copper minerals, in a gangue of iron, manganese, and aluminum oxides, often very siliceous. The oxidized ore is often of very high grade. Beautiful specimens of crystallized malachite, azurite and cuprite are fairly abundant. Surrounding the ore are large masses of nearly barren siliceous iron and aluminum oxides, passing into the unaltered country rocks.

The orebodies are usually marked on the surface by large outcrops of gossan, often copper stained.

The Copper Queen, Calumet & Arizona, and Great Western companies are each operating two shafts, and a few smaller prospecting shafts are also in operation. The Copper Queen has considerable ore developed about the Casey shaft, and is sinking the Silverton shaft to open up the eastern part of the camp. The Calumet & Arizona has large orebodies blocked out at the Germania shaft, and is sinking the April Fool shaft to develop the northern part of the camp. This company is also exploring its territory with a diamond drill. The Great Western company has fine orebodies well opened up at the Mary shaft, and also has much ore near the surface at the Humboldt shaft. At the Leadville shaft, belonging to an independent operator, some sulphide ore of good grade has been encountered.

A company has been incorporated under the laws of Arizona to build a railway connecting Courtland with Douglas, where the Copper Queen and Calumet & Arizona smelters are situated. This road, which is to be called the Colorado & Mexico railroad, will be controlled by the Phelps-Dodge interests, and operated in connection with the El Paso & Southwestern. The length of the line with its spurs will be about 45 miles. Surveys for this road are already well under way, and construction will probably be started very soon. Ore can be shipped from several of the shafts as soon as the railroad is finished.

Transvaal Gold Mines

In the cabled reports from South Africa there has been some confusion, owing to the fact that some of the reports sent were from the Witwatersrand only. The statement of the Chamber of Mines gives the values of gold for the full year from all Transvaal mines at \$133,364,858 in 1907, and \$145,703,702 in 1908; an increase of \$12,428,844, or 9.3 per cent. last year.

The labor statement gives the following comparison for three years past, showing the total number employed at mines and mills—not including Europeans—on Jan. 1 of each year:

	1907.	1908.	1909.
Kafirs..	83,567	118,204	148,722
Chinese	53,828	31,840	12,283
Total.	137,395	150,044	161,005

This shows the changes made since the passage of the law against Chinese labor. Most of the natives now coming to the mines are from north of the Zambesi, and require some time to become accustomed to the work, and to the climate of the Transvaal. The Chinese will probably disappear in the course of the present year.

*Mining engineer, Cananea, Mexico.

American Institute of Mining Engineers

A provisional program has been arranged for the 60th meeting, to be held at New Haven, Conn., beginning Feb. 23. This program is subject to such changes as may be made advisable by circumstances not now foreseen. The sessions will be held in North Sheffield hall of Yale University. The leading topics of discussion to be presented at the first three sessions are stated below. It is understood that if the special topic assigned to any one of the first three sessions should require either more or less than the time provided, the pending discussion may be adjourned, or papers on other subjects may be introduced.

Tuesday evening, Feb. 23. Opening session. Leading topic: The Conservation of Natural Resources. Papers by Dr. James Douglas and others.

Wednesday, Feb. 24. Morning session. Leading topic: A Sea-level Canal at Panama. Afternoon session. Leading topic: The Technical Education of Mining Engineers. After the latter session a visit will be made to the Hammond laboratory and other buildings of Yale University. Evening session. Papers on general subjects.

Thursday, Feb. 25. Morning and final session at New Haven for the reading and discussion of papers. It is, however, probable that a supplementary session of this meeting will be held at New York City in March, 1909, as a joint session of the Institute with other national engineering societies, for the further discussion of the Conservation of Natural Resources.

On Thursday afternoon, visit to the works of the National Pipe-Bending Company (exhibiting the electric, oxy-acetylene, and thermit processes of welding); the plant of the New Haven Gas Company, and the Bigelow boiler works. On Thursday evening a reception will be given to members and guests of the Institute by the governing board of the Sheffield Scientific School, at Byers Memorial hall.

Friday, Feb. 26. Excursion, embracing visits to the Farrel Foundry and Machine Works and the brass and copper rolling mills of the Coe Brass Company, at Ansonia; reception and luncheon at Bridgeport, tendered by the Bridgeport Board of Trade; and visits to the Locomobile works, the American Tube and Stamp works, and the works of Crane & Co., at Bridgeport.

On Friday evening, Dr. R. W. Raymond will deliver at North Sheffield hall, in the Sheffield scientific course, a lecture on the Influence of Geology upon the History of Jamaica, to which members and guests are invited.

Saturday morning, Feb. 27. Visit to the Cos Cob power plant of the New

York, New Haven and Hartford railroad. Arrangements will permit members returning to New York on Saturday to join.

PAPERS ANNOUNCED

The majority of the papers in the following list will be, as usual, read by title, or presented in brief oral abstract only. Printed copies of many of them will be on hand at the sessions:

1. Conservation of Natural Resources. By James Douglas, New York.
2. The Work of the National Conservation Commission in Relation to Mineral Resources. By Joseph A. Holmes, Washington.
3. Conservation of Natural Mineral Resources of the United States. By John Birkinbine, Philadelphia.
4. The Mineral Wealth of America. By R. W. Raymond and W. R. Ingalls, New York.
5. The Future Supply of Iron Ore. By Henry M. Howe, New York.
6. A Sea-Level Canal at Panama—A Study of Its Desirability and Feasibility. By Henry G. Granger, Cartagena, Colombia.
7. Technical Education of Mining Engineers. By Cortlandt E. Palmer, New York.
8. The Mining Course at the Sheffield Scientific School, Yale University. By John D. Irving, New Haven, Conn.
9. The Hammond Mining Laboratory at Sheffield Scientific School, Yale University. By Louis D. Huntton, New Haven, Conn.
10. Biographical Notice of James D. Hague. By R. W. Raymond, New York.
11. A Proposed Hydraulic Gold Dredge. By Henry G. Granger, Cartagena, Colombia.
12. The Residual Brown Iron Ores of Cuba. By C. M. Weld, New York.
13. Pressure Fans vs. Exhaust Fans. By Audley H. Stow, Mayberry, W. Va.
14. Blast Pressure at Tuyeres and Inside the Furnace. By R. H. Sweetser, Columbus, Ohio.
15. The Limit of Fuel Economy in the Blast Furnace. By N. M. Langdon, Mancelona, Mich.
16. Pan-Amalgamation; an Instructive Laboratory Experiment. By H. O. Hofman and C. R. Haywood, Boston.
17. The Concentration of Silver-Lead Ores. By V. T. Stanley Low, Broken Hill, Australia.
18. Shine Treatment on Vanners. By Rudolf Gahl, Morenci, Arizona.
19. The Leaching of Low-Grade Copper Ores. By A. L. Sweetser, Boston.
20. The Influence of Bismuth on Wire-Bar Copper. By H. N. Lawrie, Portland, Oregon.
21. Metal Losses in Copper Slags, and a Means of Reducing Them. By Lewis T. Wright, San Francisco.

22. The Laws of Fissures. By Blaney Stevens, Seattle, Washington.
23. The Geology of the Mount Morgan Deposit. By J. Bowie Wilson, Sydney, Australia.
24. Kentucky Fluorspar, and Its Value to the Iron and Steel Industry. By F. Julius Fohs, Lexington, Ky.
25. The Association of Vanadium with Hydro-Carbons. By D. Foster Hewett, Pittsburg.
26. Discussion of the paper of John Hays Hammond, "Professional Ethics." By Henry Louis, Newcastle, England.
27. Discussion of the paper of J. J. Rutledge, The Clinton Iron-Ore Deposits of Stone Valley, Huntingdon County, Penn. By William Kelly, Vulcan, Mich.
28. Discussion of the paper of Carl Scholz, Effect of Humidity in Mine Explosions. By Howard N. Eavenson, Gary, W. Va.
29. Discussion of the paper of Albert Bordeaux, The Silver Mines of Mexico. By Alfred H. Bromly, Mexico.

THE ANNUAL ELECTION

The following list comprises all the nominations so far received for officers and members of the council, to be voted for—in person or by proxy—at the annual meeting, which will be held at the office of the Institute in New York, Feb. 16: President, D. W. Brunton, Denver, Colo.; vice-presidents, H. V. Winchell, St. Paul, Minn.; W. L. Saunders, New York; W. C. Ralston, San Francisco; councillors, A. C. Humphreys, New York; W. G. Miller, Toronto, Ont.; Karl Eilers, New York; secretary, Dr. R. W. Raymond, New York.

A Novel Belt Conveyor

A novel arrangement of belt conveyers is a combination of two belts at right angles to each other recently installed by the Robins New Conveyor Company, New York, for the power house of the Buck Eye Pipe Line Company, Green Springs, Ohio. The problem to be solved was the storing of coal in an overhead bin. While this could be accomplished by two lines of belt conveyers, yet with a combination of a main belt and a cross belt in the same plane but perpendicular to it, one of the long belts is done away with, thereby saving 100 ft. or more of conveyer, besides having a simpler and less expensive outfit. The main belt is of the usual Robins' type with a tripper to which one end of the cross-belt is attached and the other supported by a rail fastened to and extending along the side of the building. The tripper and cross-belt thus move as one.

Colliery Notes

A nitroglycerin explosive is less sensitive with a small diameter cartridge, but an ammonium nitrate explosive is more sensitive with a small diameter cartridge.

Telephonic or telegraphic communication between various parts of the workings of all coal mines and the manager's office, or other suitable place at the shaft head, should be compulsory in all dangerous mines; similar lines of communication should be maintained from the offices to the fan and engine houses and rescue stations.

In many European mines where shots have been fired by electricity, the custom has been to use primary batteries. The latter are less costly to start with, but soon get out of order, and as a consequence, many superintendents now advocate the use of a good magneto machine, which is more reliable, and although it costs considerably more, it is easily kept in good order.

A recently published record of underground costs for working a 2-ft. seam of coal as compared with similar expenses incurred in working an 8-ft. bed showed a difference in cost of 17c. per ton in favor of the thicker seam. The cost sheet from which the figures were taken is complete in every detail and gives a fair idea of the extra expense that will result when we attempt to work our very thin seams.

As a general rule, a coal seam with heavy top and highly pitched, is best worked with a stepped face, which permits a better control of the weight. In a flat seam or one that is only slightly inclined, where mining machines are employed, if the roof will permit, it is best to work such a seam with a straight face so as to eliminate the necessity of moving the cutting machine from place to place.

The two principal dangers which arise through want of sanitation in mines are (1) spread of ankylostomiasis, and (2) spread of typhoid fever. Concerning the first disease, it is a matter of record in German mines that ankylostomiasis was not a serious matter until they commenced to water the mines. The Germans, however, were compelled to choose between two evils, and they preferred to be free from the danger of dust explosions, at the same time adopting other methods of dealing with ankylostomiasis, with the result that they have practically stamped out the disease; this successful outcome, however, cost them a lot of money, and for a time disorganized trade in some districts.

It is a matter of considerable importance to properly decide the direction of working when a coal seam has cleavage planes running through it. Such planes are commonly known as "face" and

"butt." The question of safety is the first and most important consideration in determining the direction of working. If the bed contains many "slips" running parallel to the strike of the seam and on into the roof, it would be advisable to drive the face in an oblique direction, generally known as driving "half-on." This same direction of working is also most desirable in a soft seam with heavy top, for it gives the greatest percentage of round coal. In a hard seam, it is best to work the coal on the face so that the weight of the roof will assist in breaking down the cut and thus doing away with much shooting.

As the roof at the coal face of a long-wall working is partly supported by the timber, and partly by the coal itself, it is most important to arrange the props in such a manner that the coal has just sufficient weight thrown upon it to cause it to work easily. One authority states that at such a face, the packs should be built entirely of hard lumps, as large as can be obtained. It is also suggested that in such a case, the goaf be completely stowed; this enables the roof in the roadways and at the face to settle down gradually, and also prevents any large accumulation of gas, at the same time permitting the air current to be more easily conducted along the face.

At an English colliery, where considerable attention has been directed to the proper sanitation of the underground workings, the manager has erected closets near the pit bottom and near one of the principal roadways of the mine; it is purposed extending the accommodation which has already been provided, to other parts of the mine. Each closet is situated in a brick structure, provided with a wooden door, and consists of a galvanized iron pan containing coal dust placed underneath a wooden seat. Each closet is satisfactorily ventilated with an iron pipe placed over the pan and communicating with the return airway. The total cost of such a closet, including brickwork is less than \$25. One of the stable men empty the pans about twice a week, by taking the contents to the surface. It is stated at this mine that such sanitary arrangements are not necessary at the working face.

The increase in accidents due to hang-fires only emphasizes the fact that at all mines, there should be a rule forbidding miners to return to the place before a certain prescribed time, say, one-half hour, has elapsed after the shots have been exploded. Many of these hang-fires are due to the flash of hot gases of one shot igniting the fuse of another which has been prepared at the same time, and which is intended to be fired immediately after. Others again, are due to the hemp of the fuse being left smoldering by an

ineffectual attempt to ignite the core; the man already having lighted another shot is forced to leave the place, and in his absence the smoldering hemp fires the core. When the first shot has exploded, the man returns with the object of completing the task he thinks he has left undone, and is caught by the delayed explosion. Electric shot-firing largely eliminates hang-fires.

Few mine managers fully realize that "friction" is the important item to look after in the operation of a mine. In ordinary underground haulage, 50 per cent. of the energy developed is often expended in overcoming friction. It is in colliery ventilation, however, that frictional resistance becomes the all-important consideration, for in this work practically all of the energy applied is expended in overcoming friction. A full realization of this fact can best be obtained by remembering that, in mine ventilation, if friction were entirely absent, a difference of pressure equal to a water column one-quarter inch high (1.3 lb. per sq.ft.) would be sufficient to produce a movement in the air current equal to more than 2000 ft. per minute. To attain this velocity at a colliery with large well-kept airways, however, it would be necessary to have a pressure equal to a 7- or 8-in. water gauge; this shows the necessity of devoting much attention to the elimination of avoidable friction.

Two of the most delicate tests for gas in a mine are known as the Pieler and the Clowes methods. The Pieler lamp burns alcohol and is similar to the Davy in construction. Air is admitted to this lamp through a tube which is protected by a wire gauze disk placed in the alcohol vessel in a vertical position. The Pieler lamp is a good gas tester, as it will plainly give a cap when less than $\frac{1}{4}$ per cent. of gas is present. The great difficulty with this lamp is that even a mild amount of heat causes the alcohol to take the form of a vapor, which latter is highly explosive when mixed with air. This lamp is also easily extinguished. The Clowes lamp burns hydrogen gas and shows the percentage of firedamp present by means of a scale on which the height of "cap" is recorded. In the Clowes method of testing gas, an ordinary safety lamp may be used, providing it has a hole through the oil vessel. Through this hole a steel tube is inserted, and is connected to a steel cylinder on the outside of the lamp, the steel tube coming on a level with the oil flame. Inside the steel cylinder, compressed hydrogen is stored and is regulated by a screw valve. When about to test for gas, the hydrogen is turned on and becomes ignited by the oil flame; the latter is then turned out, and the height of the hydrogen flame is regulated by adjusting the flow of hydrogen from the cylinder.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, President and Treasurer ROBERT MCKRAN, Editor.
505 Pearl St., New York.
London Office: 6 Bonnerie Street, London, E. C., Eng.
Cable Address: "ENGINEERING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage, in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs. Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.
Our circulation for January, 1909, was 54,000 copies.

February 6, 1909, 12,000

None sent free regularly, no back numbers. Figures are live, net circulation.

The Question of Prices

It is admitted that the commercial depression of 1907-09, as acute in Great Britain, Germany and elsewhere as in America, resulted from the world's living beyond its means, one of the concomitants of over-expansion and extravagance being the boosting of commodity prices. To regain the full measure of prosperity it is necessary to practice economy, to accumulate savings. As *The Evening Post* remarked the other day, it may seem ridiculous to preach economy "to a country which is talking of an issue of \$500,000,000 in bonds for the Panama canal, and habitually thinks in hundred millions, but it is the tiny savings that make the big loans possible."

But if the cost of labor and material continue so high as to check work that ought to be done; if men continue, therefore, to be out of employment; and if the cost of living is unameliorated—How are people going to save? Are they not rather bound further to diminish their accumulations?

The answer is in the negative if the theory of the trusts—both of capital and of labor—be correct. The trust magnates have reasoned that if the world will not row pay for their goods the price demanded, sooner or later it will have to do so. Diminished competition and command of vast credit have fortified them in this defiance of the law of supply and demand. Labor unionism, true to its fallacy that work is a boon to be distributed rather than a factor in the creation of wealth, has preferred to waste time rather than consent to a reduction of wages.

Since the nadir of 1908 there has been a betterment of conditions, to which many things bear testimony. The index numbers have been a little more favorable to revival of consumption, but after all they did not decline far below the zenith of 1907; nor did wages. Has it not been this very resistance to economic laws that has protracted the commercial depression? It is undeniable that now, close upon two years since the reverse began and 12 months since business was at lowest ebb, hopes have been disappointed.

In this country the Steel Corporation has been the leading exponent of the theory that reductions of prices were unwise and unnecessary. We have repeatedly argued against that fallacy, as

have other journals. We understand that the directors of the Steel Corporation at last recognize among themselves that they were mistaken.

A Building for the Geological Survey

The Secretary of the Treasury has transmitted to Congress a communication from the Secretary of the Interior, urging the erection of a fireproof building for the Geological Survey and other bureaus of the Department of the Interior, and submitting an estimate of \$2,500,000 as the probable cost of such a building as is required. We have previously pointed out the reason why the Geological Survey should have such a building. We hope that Congress will promptly grant the necessary appropriation.

It is perhaps modesty that inspires the Secretary of the Interior to ask for a building to be used by the Geological Survey, the General Land Office and the Office of Indian Affairs in combination. We think that the Geological Survey ought to have a building of its own. This should be a monumental building like the home of the geological survey of Mexico, which adorns the capital of our sister republic. The possession of such a building would be a fitting recognition of the high esteem with which the U. S. Geological Survey is held by the scientists of the world, and everyone concerned in the mining industry of the United States would be pleased.

The Yukon Gold Company

S. R. Guggenheim, president of this company, has issued to the stockholders a letter concerning the object of the enterprise, what has been accomplished and what is still to be done, estimated earnings, etc. His statement is frank and to the point, except that no data as to the operating costs are given. However, if he accepts the facts as stated, together with the estimate of the profits, the stockholder is able to form a fair idea as to the value of his property.

At the time of the Lawson flotation, the net profit of the developed ground was estimated at \$30,000,000. It is now stated that \$40,000,000 net is to be expected. The earnings in 1908 were about \$550,000. In 1909 they are expected to be \$1,100,000

to \$1,500,000. In 1910 the net profit "should be from \$2,000,000 to \$2,500,000 and in 1911 and thereafter \$2,500,000 net per annum should be the minimum."

This gives, for the first time, notice of the time that the management contemplates for the working out of the property, which apparently will be 16 to 20 years. This is in line with the analysis in the *JOURNAL* of April 18, 1908. Unfortunately, Mr. Guggenheim does not give any indication of what part of the estimated net profit will be applicable to the payment of dividends, and what part must go back into the property for maintenance. Perhaps he means that it will all be available for dividends. There is always a vagueness about the term "net profits." In the case of the Yukon Gold Company it might have been dissipated if Mr. Guggenheim had gone into the matter of gross yield and operating expense.

The discredit arising from the Lawson connection has deprived this company of the recognition to which it is entitled. Mr. Guggenheim's letter appears to be inspired in part by the desire to correct the false impression. The company is, indeed, engaged in a great industrial undertaking. Some extraordinary engineering feats have been accomplished and the introduction of new methods marks an era in Alaska placer mining. To O. B. Perry, the managing engineer of the company, is chiefly due the credit for this.

The Steel Corporation in 1908

The United States Steel Corporation in 1908 passed through the worst period of depression it has encountered since its first organization. This period followed the best year in its history, and the contrast was much greater than that between 1903 and 1904. It is true that through its influence and diplomacy it was successful in some degree in preventing the fall of prices which has marked previous years of depression; but it is a question whether the business which might have been secured by concessions would not have put the company into better condition than it occupies at present.

Speaking briefly of the results of the year, the net earnings over operating expenses were \$69,138,154 less than in 1907, and were smaller than those of any year since 1904. They were sufficient, however, to meet all the fixed charges and the divi-

dends on the preferred stock, and also to continue the 2 per cent. which the company has for several years paid on the common stock. This was done by cutting down the depreciation and renewal charges to the lowest possible point, and by omitting all appropriations for new work and construction. These had been on a liberal scale for three years, and in 1906 and 1907 had amounted to the great sum of \$57,500,000 in each year. That the maintenance of dividends was possible in a year when the net earnings fell off 43 per cent., is an evidence of the large profits earned in the boom years.

The monthly earnings in the latter part of 1907 showed the sharpest fall on record, decreasing from a maximum of \$17,052,211 in October to \$5,014,728, or less than one-third of the former amount in December. This fall was not without warning, however, for the tonnage of unfilled orders, as reported at the end of each quarter, began to fall off early in the year, and continued to decline steadily. In 1908 the monthly earnings began to improve from January on, but the advance was very slow, though in December the net earnings were \$3,000,000 above those of January.

What the effect on the revival of business might have been had the Steel Corporation encouraged construction and investment by a general reduction in prices, has been heretofore discussed. There can be no doubt that such a course would have hastened the recovery of trade. It appears now the managers have at last seen their mistake, and are prepared to try the opposite course, so that price reductions may be expected.

The Cost of Labor

The Ways and Means Committee of the House of Representatives, which is engaged in drafting a new tariff bill, appears to be profoundly concerned as to the lower rates of wages in foreign countries. This is to a large extent a waste of thought. Modern economists seem to be fairly well agreed that differences in the wage rate cut comparatively little figure. It may be stated as a general rule, to which, of course, there are some exceptions, qualifications and limitations, that the laborer is worthy of his hire. Where labor is low the performance per man is generally correspondingly low.

Legislative Inquiry Concerning Cave-ins over Anthracite Mines

The question of responsibility for cave-ins of the surface over anthracite mines, where damage to property has resulted, has been a constant litigation in the mining districts of eastern Pennsylvania. The towns in the anthracite region are almost without exception underlain by seams of workable anthracite coal. The increasing value of this product, combined with the depletion of the easily accessible beds, has caused the larger anthracite companies to mine as much coal from beneath the towns as can be obtained without injuring the surface. In many instances, however, the limit of safety has been exceeded, with the result that the buildings on the surface have been wrecked.

In answer to a petition submitted by the mayors of five cities and the burgesses of 13 towns, Governor Stuart has just sent a special message to the General Assembly recommending the creation of a commission with authority to inquire into the subject and make a report to the next legislature.

The work of the commission will be important; however, it will face a problem that has already been solved in European countries. Some anthracite operators have indeed anticipated such action, and have introduced flushing systems, whereby the worked-out portions of their mines are filled with culm and waste material, thus permitting the extraction of all pillars, without injury to the surface. This system adds somewhat to the cost of the coal produced, but insures a greater recovery.

There is no reason why many square miles of surface in the anthracite region should be made insecure, if not worthless, by the refusal of a few mine operators to adopt methods that have already been tried and proved successful.

WHILE THE FEDERAL GOVERNMENT is concerning itself so much as to conservation of resources and the reduction of waste, why does it not begin with itself and eliminate some of the scandalous wastes that go on in the administration of its own affairs?

Views, Suggestions and Experiences of Readers

Comments on Questions Arising in Technical Practice and
Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Electric Shocks and Fires in Mines

The article on "The Use of Electricity in Australian Collieries" in the JOURNAL of Nov. 14, 1908, is exceedingly interesting. The troubles Selwyn Brown points out as having been experienced in Australian mines, are exactly those that have been experienced in English mines. There has been the same trouble with the exposure of live metal, and from the deterioration of the insulation of cables, and from cables being stripped.

I venture to think, however, that the workmen of New South Wales, and the New South Wales government, are wrong in endeavoring to keep the pressure employed at a very low figure. If the pressure is kept at a figure which is safe under all circumstances, it will render the use of electricity in mines absolutely prohibitive, on account of the enormous cost of the cables. In one case which passed through my hands, the difference between employing 2000 volts, and 500 volts, for cables alone, I estimated at \$30,000.

On the other hand, once the limit of safe voltage is passed, there is no reason why as high voltages as the management chooses, within very wide limits, should not be employed. About 140 volts in alternating current kills, and about 400 volts in continuous currents. Once those pressures are exceeded, the danger is practically the same for all pressures, so far as the men about the mine are concerned, until rather high voltages are reached, and then the paradox arises, that, owing to the burning effect of the arc which is almost invariably produced when a man touches a very high pressure conductor, greater safety is enjoyed than with pressures just above the limit.

SOURCES OF DANGER

The great danger from shock in mines arises from conductors' being stripped of their insulation, and making connection with some other innocent-looking metals. A stripped conductor may transmit the ability to give shock, to some metal at a considerable distance from it, that is not actually in contact with it, but which is in contact with a second piece of metal, or even a third, the second or the third being in contact with the live conductor. A girder has accidentally stripped the covering of an insulator, and has killed a man handling it. The insulating envelop of the flexible cable carrying current to a

coal cutter has been punctured, and the man moving the haulage rope has been killed. Naked galvanized-iron wires employed for signaling, have been rendered "live" by one or two connections, and have killed men touching them. The remedy for all is the provision of very good insulation, and as much of it as funds will allow, in the first instance, and its careful maintenance after.

Fires have unfortunately been caused in not a few cases, in mines, by the arc that has been formed between a pair of broken conductors, or between one of them and the rails, when coal dust has been present in a position to be ignited. The continuous current arc is far more liable to cause fires than an alternating current, and the danger of the arc's causing fire increases with the pressure.

SYDNEY F. WALKER.

Bath, England, Dec. 4, 1908.

Adair-Usher Process in Pachuca

In the JOURNAL of Sept. 5 and 19, 1908, there is a reference to the so-called failure of the Adair-Usher process at Pachuca, Mexico, where it had been installed by the Blaisdell company for trial under working conditions.

It was never contemplated by us that this process would be applied to anything but slimes, and we should certainly have endeavored to stop its use under the conditions prevailing at Pachuca, had we known that mining as practiced in Mexico had not reached the stage of complete separation of sand and slimes as performed here on the Rand.

The presence of large quantities of silver or any other metal in the ore, provided it is amenable to cyanide or any other lixiviating treatment is no detriment at all to the process, as we presume that cyanide managers in America endeavor by some means, such as circulation or agitation to get the gold and silver completely dissolved, or as nearly so as possible, before washing is commenced.

We inclose a list of the mines on which our process has been successfully worked on the Rand, and we are convinced that under similar conditions in other countries the process can be worked with equally good results.

BALL & STUART, Secretaries,

Adair-Usher Process, Ltd.

Johannesburg, Transvaal, Dec. 14, 1908.

[From the statements received with this letter it appears that the Adair-Usher process has at six different mines effected reductions in the losses in the tailings varying from 5d. to 8s. At the Crown Reef, where 8000 tons per month were subjected to the process, the time of treatment was reduced from 5 days 8 hours to 3 days and 14 hours. At the New West Bonanza the gold in the tailings was reduced from 2.50 to 0.75 dwt. per ton.

The process is either in successful use, or in course of installation at plants of the following mines and companies: Crown Reef, Geldenhuis Estate, Treasury, Geldenhuis Deep, Worcester Exploration, Geldenhuis Main Reef Tributors, West Rand Mines Slimes Tributors, New Heriot, Cinderella Deep, Robinson Randfontein, Champ d'Or, Durban Roodepoort, Ferreira, Transvaal, Jumpers, New West Bonanza, Durban Roodepoort Tributors, Burnham Slimes Tributors, Nigel, West Rand Mines, Langlaagte Estate, Tributors Molyneux Gold Mines, Ginsberg, Blaisdell & Co., Consolidated Main Reef and Estate, Glynn's Lydenburg, Jubilee, Paarl Central Slimes Tributors, Nourse Mines, Salisbury.—EDITOR.]

Withdrawal of Western Phosphate Lands

The remarks in the JOURNAL of Dec. 19 on this subject coincide fully with my own views. The stand taken is good, sound Americanism, however little it may agree with the views of certain exploiters of American resources for foreign profit.

In the light of the present withdrawal of phosphate lands I believe the letters which I inclose may be of interest as being the first suggestion along that line. President Roosevelt by this far-reaching decision has done an incalculable service to the American nation, and if it were feasible to follow this up and render the exportation of phosphate prohibitive, notwithstanding present curses from certain quarters, future generations would arise and call him blessed.

The JOURNAL did me the honor in May, 1907, to publish the first article that appeared concerning the Western phosphates. About the same time the subject was treated by the U. S. Geological Survey in "Contributions to Economic Geology for 1906, Part 1," in which almost

the opening sentence it spoke of the business to be built up possibly in supplying Australia and Japan. Fortunately recent discoveries in the Pacific islands do not now make that feature of the business so attractive, and I thoroughly agree with the JOURNAL that American phosphate deposits should be conserved for the American people.

If now, while the western business is in its infancy, a fair plan can be evolved whereby the United States can recover title to the deposits already located and patented it would seem the logical sequence to the present withdrawal of phosphate lands.

It might be accomplished by 50-year leases with the fixed royalties to be an offset against the present actual cost of the properties to the different companies and individuals until these costs had been extinguished and they had been reimbursed through that source, after which the royalties to become payable to the Government. Some such plan could be made equitable to all parties and finally place in the hands of the Government this veritable backbone of the nation.

CHARLES COLCOCK JONES.

Los Angeles, Cal., Dec. 24, 1908.

[The correspondence referred to in Mr. Jones' letter is too voluminous for publication in these columns. A letter dated Oct. 16, 1906, and addressed to President Roosevelt, urges the withdrawal of the phosphate lands from mineral entry, and one from H. C. Rizer, acting director of the U. S. Geological Survey, dated Nov. 1, 1906, recognizes the force of Mr. Jones' suggestion and requests further information on the subject.—EDITOR.]

The Milan Mine, New Hampshire

George A. Packard is in error in stating in his article in the JOURNAL of Jan. 9, 1909, that the Milan mine in 1908 shipped several carloads of ore said to run 5 per cent. copper and as high as 50 per cent. silica. The fact is that we shipped to the American Smelting and Refining Company two trial carloads of ore which showed the following analysis: Copper, 8 per cent.; silica, 7.8; sulphur, 38.18; iron, 31.83; gold, 0.08 oz. and silver, 4 oz. per ton. Subsequent to this, we shipped in 1908 nine schooner-loads of ore which averaged from \$8 to \$10 per ton in metallic contents at the smelter. We expect in a short time to have our new milling and ore-dressing plant in operation.

J. B. CARPER, President and Manager,
Milan Mining and Milling Company.

Jan. 15, 1909.

An average of 2338 machine drills were in operation during the first six months of 1908 at the mines on the Rand, South Africa.

The Conservation Commission

SPECIAL CORRESPONDENCE

The next forward step in the conservation movement has been taken by Chairman Pinchot in transmitting to President Roosevelt the report of the National Conference on Conservation, accompanied by the complete text of the proceedings of the conference. President Roosevelt has sent the report to Congress (Jan. 22) with a message urging certain important legislative acts. Simultaneously with this step, Mr. Pinchot has announced the personnel of the joint committee which is to represent the States and the Federal Government in making plans for the development of a conservation policy. Six of its members are chairmen of State conservation commissions, and three are members of the national conservation commission, besides the chairman and secretary of the national body. The membership of the committee is as follows: Representing the State conservation commissions: J. N. Teal, Portland, Ore.; Paris Gibson, Great Falls, Mont.; W. K. Kavanaugh, St. Louis, Mo.; W. H. Milton, Marianna, Fla.; Prof. Frank W. Rane, Boston, Mass.; O. J. Salisbury, Salt Lake City, Utah. Representing the national conservation commission, Knute Nelson, Alexandria, Minn.; Newton C. Blanchard, Shreveport, La.; George C. Pardee, Oakland, Cal. Gifford Pinchot is chairman, and Thomas R. Shipp, secretary. These men were selected with a view to having all sections of the country represented on the "Joint Committee on Coöperation," as it will in future be known. All have taken an active part in the conservation movement, and are said to be thoroughly familiar with the situation in their own districts.

President Roosevelt in his message speaks of the report of the commission as "one of the most fundamentally important documents ever laid before the American people." He says that "the facts set forth in this report constitute an imperative call to action and adds "with the statements and conclusions of this report I heartily concur." The President recommends the organization of efficient fire patrols and the enactment of good fire laws by the States, while he indicates the necessity of such a reformation of State taxation as will permit the perpetuation of existing forests. As to lands he thinks that the remaining public lands should be classified, the arable lands disposed of to home-makers, the timber and stone act and the commutation clause of the homestead act be repealed and the desert-land law be modified in accordance with the recommendations of the public-lands commission. He further suggests that the use of the public grazing lands be regulated, while "rights to the surface of the public land should be sepa-

rated from rights to forests upon it and to minerals beneath it, and these should be subject to separate disposal." Also "the coal, oil, gas, and phosphate rights still remaining with the Government should be withdrawn from entry and leased under conditions favorable for economic development." In dealing with the subject of minerals, Mr. Roosevelt, accepting the estimates of the conservation commission, reckons the present mineral waste at about one-sixth of the product. The President further points out that mineral resources are limited in quantity and that the supply will shortly be exhausted unless better methods are devised or substitutes are found. Further investigation, he thinks, is urgently needed in order to improve methods and to develop and apply substitutes. He then adds: "It is of the utmost importance that the bureau of mines be established in accordance with the pending bill to reduce the loss of life in mines and the waste of mineral resources and to investigate the methods and substitutes for prolonging the duration of our mineral supplies. Both the need and the public demand for such a bureau are rapidly becoming more urgent. It should coöperate with the States in supplying data to serve as a basis for State mine regulations."

The report of the conservation commission as transmitted by the President covers ground already dealt with in this correspondence. A few important changes have, however, been introduced into the inventory of natural resources, some figures being modified and certain additions made. The report in dealing with minerals takes the view that while waste is still very great, there has been progress in ascertaining methods of economy. This is particularly true in the case of coal, the present mine waste averaging little more than half the amount saved, and the chief waste occurring in connection with imperfect combustion. It is pointed out that the uses of all the mineral resources are interdependent and that this is particularly true of coal and iron. Special stress is laid on the necessity of protecting phosphate rocks used for fertilizers, inasmuch as the original supply cannot long withstand the increasing demand. A plea is also made for the saving of fire losses which are said to have approximated \$450,000,000, or one-half the cost of construction in 1907. Of lands it is generally claimed that the present public land laws do not serve the interests of the nation, and that they should be reclassified and mineral rights disposed of separately from the lands themselves under a lease system. The usual recommendations with reference to forestry and water power are made, and in conclusion it is argued that the conservation of resources is an immediate and vital concern. "The pressing need is for a general plan under which citizens, States, and nation may unite in an effort to achieve this great end."

Operations of the Yukon Gold Company

The following letter to the stockholders of the Yukon Gold Company was issued by President S. R. Guggenheim on Jan. 30, 1909:

In submitting for your consideration a résumé of the company's mining operations, construction work, and plans for further equipment, I desire to call your attention to the magnitude of the undertaking in the Klondike district, Yukon Territory; what has been accomplished thus far, and what we expect to accomplish within the next two years.

At the time our engineers made their first examination in 1905, the famous placer fields of the Yukon were fast becoming depleted of their rich ground; the volume of gravel workable at a profit by hand method was rapidly being reduced, and the cost of working, under the most approved methods then in vogue, precluded the extension of the operations to take in the large bodies of lower-grade material.

The principal factors making toward the high cost were:

(1) The disconnected nature of the holdings (the claims being not over 500 ft. in length and owned largely by individuals), which reduced the workings to a number of small-scale operations, and prevented systematic mining upon any larger scale.

(2) The scarcity of water. The miners, both those working upon the creek levels and those upon the bench and hill deposits, were entirely dependent upon the rain-fall for their supply of water. As the snow and rain-fall is very irregular in the Klondike district, a corresponding irregularity entered into the mining operations, with a consequent increase in cost. No large scale hydraulic operations were possible with such limited and intermittent water supply.

(3) The high cost of fuel, labor and supplies. Wood fuel is available in the Klondike for mining purposes, but its cost is high and constantly increasing. Coal is to be had, but it is as expensive as wood. Labor is high, due to the short season for outside work, and supplies expensive because of high transportation charges, and the small and irregular character of the purchases.

BASIS OF THE ENTERPRISE

Our investment in the Yukon was based upon three fundamental hypotheses:

(1) That we would be able to acquire large and connected blocks of ground for systematic working.

(2) That we would be able to secure and make available, at sufficient elevation a continuous water supply.

(3) That we would proceed to equip the properties with the most modern me-

chanical appliances, such as dredges and elevators, for handling the gravels upon a large scale and at a low cost, depending for power not upon local fuel, but upon electrical energy generated in our own hydro-electric plant.

All of these things have been accomplished. At the present time our holdings amount to about 90 per cent. of the claims located on the hills and creek bottoms of Bonanza, Bear, Hunker, and El Dorado valleys, which were wanted for the enterprise. These properties have been acquired mainly by outright purchase, although in some cases, where unacquired claims adjoin the properties of this company, advantageous working agreements have been made with the owners.

Early in 1906 construction was begun upon a water system which will insure to the Klondike a continuous water supply for all time. This was in itself a tremendous undertaking, involving the diversion of Tombstone river (the main right fork of the Twelvemile), carrying it a distance of about 62 miles by flume, ditch and pipe lines, through a country which was an absolute wilderness when our engineers first went upon the ground. In its course the main ditch follows the contour of the country, which, due to its rugged and partly frozen character, required miles of continuous flume construction. The line crosses five depressions, making an aggregate of nearly 12 miles of pipe line. The ditched sections, aggregating 37 miles, required the use of seven steam shovels in excavation, and the employment of more than 1000 men throughout three summers. The water is carried across the wide Klondike valley in an inverted siphon, which for length, size and pressure involved, is not, so far as we know, equalled in the world.

CONSTRUCTION

The construction of this water system was carried on in the face of great difficulties. It involved the distribution of thousands of tons of supplies and construction material; the manufacture, distribution and use of more than 8,000,000 ft. of lumber, produced by our own logging and sawmill operations; the hauling over winter roads; and distribution of several thousand tons of steel and wood-pipe line; and its installation at an average distance of 35 miles from the base of supplies.

In the construction of the flume, ditch and pipe line, innumerable engineering difficulties were encountered and overcome, which would not be met anywhere, except in the far northern country. The complete work today is evidence of persistent and untiring effort upon the part of the men in charge. Many of the engineering feats accomplished have prompted praise from the technical press. They mark an era in Alaska mining history.

Simultaneously with the construction of the water system, a hydroelectric power

plant was installed on the Little Twelvemile river, capable of delivering 2000 h.p., which is transmitted to the placer fields by a high-tension line, 36 miles straight across country, with three substations and 18 miles of secondary line.

A huge dam has been built at the head of Bonanza creek to conserve the water of the Upper Bonanza watershed for use upon the company's Bonanza and El Dorado Creek properties.

Equipment plans have been carried forward in a manner to evoke enthusiasm and inspire confidence in a speedy consummation of the enterprise as a whole. Seven dredges have been erected, the last of which was completed and put in operation late in the season of 1908. These dredges are of large capacity and great strength, able to withstand the most severe service. Their operation in the latter part of 1908 demonstrated the entire success of this method of mining, as applied to the gravels of the Yukon. The difficulties due to frozen ground have been overcome within the limit of a reasonable working cost, and this cost will, without doubt, be greatly reduced when the main water supply is available for stripping the gravels in advance of the dredges.

Three mechanical elevators were installed, two of which were put into operation during the season of 1908. It is a great pleasure to say that the mechanical elevators, electrically driven, which were designed by our own engineers and used here for the first time in any country, were entirely successful. They will be presently operating upon the ground from which the gold could not be thoroughly extracted by any other method of mining known to us. The successful operation of the elevators solves one of the most difficult problems in connection with our Yukon business—that of handling flat, shallow gravels, largely frozen, where the bedrock is rough and irregular and the gold extends to some depth into the crevices.

Since acquiring the properties in the Yukon, we have carried on hydraulicking to a limited extent, and dependent upon the local intermittent water supply. The operations have shown a profit, and have proved not only the value of the gravel, but also that a very low working cost can be reached.

In the season of 1909 we expect to have the equipment working up to at least one-half of its ultimate capacity. In the season of 1910 we fully expect to show a production which will make the Yukon Gold Company take rank as one of the largest gold mines in the world.

HOLDINGS AND PROVED GROUND

We have only proved our holdings in part, first, because of the advisability of concentrating our engineering staff upon the installation of the present equipment, and second, because of the expense attendant upon the thorough prospecting of

ground in the north. Our engineers having reported that we now have nearly \$40,000,000 net in proved ground, which is approximately 100 per cent. profit on the shares at par, and provides for many years' dividends, we concluded to postpone further prospecting of our holdings, until our present plant and equipment are running to full capacity. There is good reason to believe that additional workable ground will be developed and economies introduced which will greatly increase the ultimate net profit.

The shareholders will be interested to know that a large majority of the outstanding capital stock of the Yukon Gold Company is owned by the Guggenheim Exploration Company, whose engineers have under their direction the equipment and operation of the properties. The Guggenheim Exploration Company has financed the scheme from its inception, justifying its investment by the conclusions of its engineers after rigid examination and exhaustive reports. That the members of the company are satisfied with their investment is evidenced by the fact that they have not disposed of a share of their holdings. The fact is that the directors of the Guggenheim Exploration Company feel that they, as pioneers in the industrial development of the North, have taken the first steps toward the establishment of a permanent and substantial mining industry in the Yukon Territory and Alaska. The day of the small operator had come and gone, and in his place entered the corporation, to do the things which few individuals, having the means, would care to undertake; that is, to supply sufficient capital for the development of the resources of the country and make its mining future definitely assured. It required courage to make such an investment, running well up into millions of dollars, but the directors feel that the money and time they have expended in developing the resources of the North, will ultimately result in a large profit to the stockholders of the first company to go into placer mining in this region upon so gigantic a scale. That others will follow in our footsteps we hope and have no doubt, now that we have demonstrated that the frozen gravels can be worked within reasonable operating cost, and in fact that all of the handicaps under which the individual operator labored can be overcome. We feel safe in predicting, therefore, for the future, an immense increase in the gold output of Alaska and the Yukon Territory which naturally will be attended by improvement in local conditions and increasing prosperity.

PAST RESULTS

For the last season final results have not as yet been actually determined, but incomplete figures show that the net earnings to Dec. 31, 1908, will be about \$550,000. Without doubt, we should have reached our estimated net of \$800,000, had

it not been for delay in delivery at Dawson of machinery, which was held up at Whitehorse by unusually low water in the Yukon river immediately after the opening of navigation. This delay cut the length of our season materially, but possibility of repetition may be omitted from future calculations, now that our equipment has been delivered and installed.

Our engineers have estimated the probable earnings for 1909 at from \$1,100,000 to \$1,500,000. The wide difference in these figures is due to the unknown factors entering into the water supply, and the uncertainties attendant upon the first operation of a new ditch line of such length, and constructed under such difficulties. If we have comparatively few washouts or accidents on the main ditch system or the equipment, our earnings will probably reach the higher figure.

In 1910 the net profits of the company should be from \$2,000,000 to \$2,500,000, and in 1911 and thereafter, \$2,500,000 net per annum should be the minimum.

I have no doubt that the directors will authorize the commencement of dividends during this year, probably in the second quarter; but before deciding definitely as to the date and rate, they deem it prudent to wait until the coming season's operations have sufficiently advanced to enable them to estimate more accurately the probable earnings for 1909.

Chronology of Mining, January, 1909

Jan. 2—General strike of miners in New Zealand on account of Workers' Compensation Act, effective Jan. 1, requiring medical examination for certain diseases.

Jan. 4—Strike of miners at Broken Hill, N. S. W.

Jan. 5—Outside steel makers reduced prices.

Jan. 6—J. W. Gates in letter to Ways and Means Committee advocated duty-free iron ore, coal and lumber and reduction in duty on iron and steel. Tennessee Steel Company incorporated in Maine with \$20,000,000 capital stock. Pueblo Indians attacked miners of the American Turquoise Company, New Mexico.

Jan. 7—U. S. Steel Corporation offers common stock to employees at 50, besides the usual offer of preferred at 110, this being held to imply increased confidence in the common stock. Senator Culberson accuses President Roosevelt of violating law in Tennessee-Steel Trust deal.

Jan. 8—Concentrator of Arizona Copper Company, Clifton, destroyed by fire. Manufacturers of lead products petitioned Ways and Means Committee for duty-free pig lead and for duty on manufactures.

Jan. 9—Statistical number of the JOURNAL gave world's mineral production for 1908.

Jan. 10—Explosion in Leiter mine, Zeigler, Ill., killed 27 men.

Jan. 12—Organization of Copper Producers' Association to report monthly production and stock of refined copper. Announcement that Cole and Ryan had secured control of Giroux Consolidated Mines Company. Explosion at Lick Branch colliery at Switchback, W. Va., killed more than 105 men. Earthquake on Pacific coast. Goldfield Consolidated mill began dropping 100 stamps.

Jan. 13—Explosion of gas at Almassy mine, Resicza, Hungary, killed 12 men.

Jan. 14—Explosion of gas, followed by a dust explosion, at Aika colliery, Veszprem, Hungary, killed 56 men.

Jan. 19—U. S. Circuit Court of Appeals affirms decisions of Circuit Court and Board of General Appraisers that zinc ore is not dutiable under the Dingley Act.

Jan. 22—The President, in a message to Congress on the conservation of resources, recommended that the coal, oil, gas and phosphate rights still remaining with the Government be withdrawn from entry and leased under conditions favorable for economic development. Flood on the Rand, Transvaal, broke dam and flooded a mine, drowning 160 miners. Kelvin-Calumet copper properties acquired by Ray Consolidated Company, a \$5,000,000 corporation.

Jan. 24—Judge Hunt, in the Federal Court, Helena, Mont., gave a decision against the farmers in the Washoe smelter fume case, refusing the injunction asked for. Shutdowns of all the mines at Globe, Ariz., because of labor agitation.

Jan. 26—U. S. Steel Corporation quarterly report showed gain in unfilled orders.

Jan. 27—Reports multiply of price cutting by independent steel manufacturers. Explosion in Merchants coal mine of the United Coal Company, Boswell, Penn., killed five men.

Jan. 28—Copper River Railroad, Alaska, completed from Condova to Abercrombie rapids. Fire in Sutro tunnel. Comstock lode, caused minor damages.

Jan. 29—Senate begins taking testimony respecting Tennessee-Steel Trust deal. Resumption of work at Globe, Ariz.

Correction

In the article "Examining and Fitting up a Hydraulic Mine" by H. A. Brigham in the JOURNAL of Jan. 2, 1909, the last sentence of the fourth paragraph from the bottom of page 27 was transposed. It should be the last sentence in the next paragraph which should read: "A giant under heavy pressure, placed at the lower end of the sluice, may be used to great advantage in stacking or elevating the tailings whenever the dump room is ample in area but deficient in grade. Any boulders, stumps, etc., that will run through the sluice, can be elevated by this process equally as well as the fine gravel."

Pig Iron and Steel in 1908

The completed figures for the production of pig iron and bessemer steel, as collected by the American Iron and Steel Association, are now available for 1908, and show the sharpest decrease in that year which has ever been reported. The pig iron make fell back almost to that of 1907 and was only about two-thirds of that reported in the previous year.

PIG IRON

The American Iron and Steel Association has received from the manufacturers complete statistics of the production of all kinds of pig iron in the United States in 1908. The figures, as given in the *Bulletin* of the association show the total production for two years as below, in long tons:

	1907.	1908.	Changes.
First-half.....	13,478,044	6,918,004	D. 6,560,040
Second-half.....	12,303,317	9,018,014	D. 3,285,303
Total.....	25,781,361	15,936,018	D. 9,845,343

The second half of 1908 showed an increase of 2,100,010 tons over the first half; the total decrease for the year being 38.1 per cent. The division of the make according to the fuel used was as follows:

	1907.		1908.	
	Tons.	PerCt.	Tons.	PerCt.
Coke.....	23,972,410	93.0	16,331,863	96.2
Anthracite.....	1,371,554	5.3	355,009	2.3
Charcoal.....	437,397	1.7	249,146	1.5
Total.....	25,781,361	100.0	15,936,018	100.0

Very little iron is made with raw bituminous coal, and that is included with the coke iron. Nearly all the anthracite furnaces use some coke also, the quantity made with anthracite alone having been only 36,268 tons in 1907, and 1694 in 1908. A small quantity of iron was made experimentally in Michigan with producer gas as fuel; and a small quantity was made, also experimentally, in the electric furnace.

DIVISION OF PRODUCT

The more important division according to the purposes for which the iron was intended is as follows:

	1907.		1908.	
	Tons.	PerCt.	Tons.	PerCt.
Foundry & forge.....	6,397,777	24.8	4,307,734	27.0
Bessemer pig.....	13,231,620	51.3	7,216,976	45.3
Basic pig.....	5,375,519	20.9	4,010,144	25.2
Charcoal iron.....	437,397	1.7	249,146	1.5
Spiegel and ferro.....	339,348	1.3	152,018	1.0
Total.....	25,781,361	100.0	15,936,018	100.0

The bessemer pig in 1908 included 130,610 tons of special low phosphorus iron. The spiegel and ferro included 152,018 tons spiegeleisen and 40,642 tons ferro-manganese; besides a few hundred tons of ferrophosphorus.

ACTIVE FURNACES

The whole number of furnaces in blast on Dec. 31, 1908, was 236, against 168 on June 30, 1908, and 167 on Dec. 31, 1907. The number of furnaces in blast at the end of 1907 was smaller than at the close of any year since 1896, when but 169

furnaces were active. At the close of 1908 there were 223 idle furnaces, as compared with 276 idle furnaces at the opening of the year.

PRODUCTION BY STATES

The production by States for two years past was as follows:

States.	1907.	1908.
Mass. and Connecticut.....	19,119	13,794
New York.....	1,559,752	1,019,485
New Jersey.....	373,189	225,372
Pennsylvania.....	11,348,649	6,987,191
Maryland.....	411,833	183,602
Virginia.....	478,771	320,458
Georgia and Texas.....	55,825	24,345
Alabama.....	1,586,674	1,397,014
West Virginia.....	291,006	65,551
Kentucky.....	127,946	45,096
Tennessee.....	393,106	290,292
Ohio.....	5,280,687	2,861,325
Illinois.....	2,457,768	1,091,344
Indiana and Michigan.....	436,507	348,096
Wisconsin and Minnesota.....	322,083	148,398
Missouri, Colorado, Washington and California.....	468,486	313,071
Total.....	25,781,361	15,936,018

The smallest proportional losses shown in 1908 were in Tennessee and Alabama.

BESSEMER STEEL PRODUCTION

The decline in bessemer steel was even greater proportionally than that in pig iron, being 47.5 per cent. In part this was due to the increased use of open-hearth steel, which has been so much in evidence for several years past. The production by States was as follows, in long tons:

	1907.	1908.	Changes.
Pennsylvania.....	4,361,841	2,106,382	D. 2,255,459
Ohio.....	3,636,679	1,965,446	D. 1,671,233
Illinois.....	1,723,073	1,237,747	D. 485,326
Other states.....	1,965,966	817,180	D. 1,138,786
Total.....	11,687,649	6,116,765	D. 5,570,794

The totals include castings made direct from the converter, which were 33,273 tons in 1907, and 20,559 in 1908. The total production of bessemer steel was the smallest reported since 1897, when 54,753,315 tons were made. The maximum output was in 1906, when the total reached 12,275,830 tons, or a little more than double the make of last year. The largest proportional decrease was in Pennsylvania. This was probably due to the substitution of open-hearth furnaces for bessemer converters by the Carnegie works.

The figures for open-hearth steel are not yet available; but the indications are that the open-hearth was greater than the converter make last year.

RAIL PRODUCTION

The production of all kinds of rails for two years past was, in long tons:

	1907.	1908.	Changes.
Bessemer steel.....	3,380,925	1,354,236	D. 2,025,789
Open-hearth steel.....	272,704	567,304	I. 294,600
Iron.....	923	71	D. 854
Total.....	3,653,654	1,921,611	D. 1,732,043

This includes all classes of rails, re-rolled, as well as those made from new steel. The re-rolled rails were about 71,000 tons. The production of bessemer

steel rails was the smallest reported since 1896. The output of open-hearth steel rails was more than doubled, which is one result of the sharp controversy over bessemer-steel rails, which has been going on for the past two years. The open-hearth rails were made chiefly by the Bethlehem Steel Company and the Tennessee Coal, Iron and Railroad Company.

The following table gives the production of all kinds of rails, according to the weight of the rails per yard. Street and trolley rails are included:

Section:	1907.	1908.	Changes.
Under 45 lb.....	295,838	183,569	D. 111,969
45 to 85 lb.....	1,502,904	988,108	D. 514,797
Over 85 lb.....	1,767,831	1,049,544	D. 718,287
Total.....	3,633,654	1,921,611	D. 1,712,043

The total decrease in 1908 was 47.1 per cent. The greatest proportional decrease was in rails between 45-lb. and 85-lb. section: the smallest was in light rails, under 45-lb. section.

Exports of rails decreased from 338,906 tons in 1907 to 196,510 in 1908; a reduction of 142,396 tons, or 42 per cent. This was slightly less than the decrease in production, but does not indicate that export trade made up in any appreciable degree for the decline in home demand.

Balata Belts

SPECIAL CORRESPONDENCE

Balata belts have been manufactured in Scotland for the last 20 years, and while they have been extensively used in South Africa, Australia and Europe, their use in the United States is of a comparatively recent date. The Robins New Conveyor Company is now introducing them in this country. The basis of the belt is a closely woven cotton duck, and balata which is a gum, is applied in a hot liquid form, thereby saturating the plies of duck. The gum is used in an unadulterated form, without mineral or other ingredients. Balata belts are recommended for conveying and transmission purposes in damp and exposed places. In South Africa they have been widely used for carrying ore to the stamp mills.

By-product Plant for the Frick Coke Company

Reports from Pittsburgh state that the Frick Coke Company has abandoned work which was to cost \$3,700,000 on 1700 additional coke ovens at Uniontown, Penn., and will substitute for the proposed bee-hive ovens an enormous by-product coke plant at Gary, Ind. The abandonment of the projected 7000 bee-hive ovens at Filbert, 5000 at Ralph and 500 at Sarah, means that the Frick plants in those localities will hereafter be merely coal-loading plants.

The United States Steel Corporation

The publication of the earnings of the December quarter of 1908 makes it possible to give a summary of the operations of the United States Steel Corporation for the full year 1908; subject only to some slight corrections which the complete report may make. As compared with 1907 the net earnings show a decrease of \$69,138,154, or 42.9 per cent. The corporation was able to pay its usual dividends, notwithstanding this heavy decrease, by cutting off the appropriations for new work and improvements which had been made on a liberal scale in the two or three preceding years.

The income accounts for two years past can be compared as follows:

	1907.	1908.
Net earnings.....	\$160,964,674	\$91,826,520
Sinking funds.....	\$7,115,258	\$6,361,668
Depreciation and reserve.....	22,241,983	15,396,121
Interest.....	22,860,355	23,862,649
Adjustments.....	681,515	
Total charges.....	\$52,899,121	\$45,620,438
Balance.....	\$108,065,563	\$46,206,082
Add adjustments.....		289,183
Total net.....	\$108,065,563	\$46,495,265
Special improvements.....	3,500,000	
New construction.....	54,000,000	
Dividends.....	35,385,726	\$35,385,726
Total appropriations.....	\$92,885,726	\$35,385,726
Undivided surplus.....	\$15,179,837	\$11,109,539

The dividends declared were the same in both years; 7 per cent., or \$25,219,676 on preferred, and 2 per cent., or \$10,166,050, or common stock.

The gross receipts, which were \$757,014,768 in 1907, have not yet been stated for 1908. The net earnings, as published, "were arrived at after deducting each month the cost of ordinary repairs and maintenance of plants, employees' bonus funds and interest on bonds and fixed charges of subsidiary companies." These net earnings, by months, were as follows in 1908:

Jan.....	\$5,052,743	July.....	\$8,599,630
Feb.....	5,709,428	Aug.....	9,152,311
March.....	7,466,834	Sept.....	9,344,333
April.....	6,761,080	Oct.....	9,415,068
May.....	6,021,279	Nov.....	8,756,729
June.....	7,482,797	Dec.....	8,053,088

The monthly earnings showed a fair recovery from January to March, but from that month a considerable decrease for two months. From June on there was a steady advance until October, but then they fell off again, losing \$1,361,580 from October to December. The earnings of the latter month were, however, \$3,000,345 above those for January, a gain of 60 per cent. In 1907 the monthly net earnings reached a maximum of \$17,052,211 in October, the largest ever earned by the company. From that point there was a sharp fall, November recording only \$10,467,253—a loss of 38.6 per cent. from October; and December \$5,014,728, a loss of 70.6 per cent.

The report includes a statement of the total tonnage of unfilled orders at the close of each quarter for a series of years. These orders reached their highest point at 8,489,718 tons on Dec. 31, 1906. There was a decrease in 1907 to 8,043,858 tons on March 31; 7,603,878 on June 30; 6,425,008 on Sept. 30; and 6,624,553 on Dec. 31. In 1908 the figures were 3,765,343 tons on March 31; 3,313,876 on June 30, this being the lowest point reached since Sept. 30, 1904; 3,421,877 tons on Sept. 30; and 3,603,527 tons on June 30, a slight recovery from the low point of the June quarter.

Mineral Concessions in India

In practically all of the native states of India mineral rights belong to the respective rulers, and concessions for mining and prospecting are granted under rules involving some supervision by the government ("Sketch of Mineral Resources of India," by T. H. Holland). In some parts of the country surface rights, by the terms of settlement, carry mineral rights as well; however, in the remainder of the country the government retains rights over the minerals and grants concessions for exploration in accordance with the terms set down in a set of rules.

Two sorts of concessions are granted, prospecting licenses and mining leases. The former are granted only to persons holding certificates of approval from the local governments. The application for such a license must contain certain specified particulars and the holding of it entails upon the holder the following out of a number of conditions. These are clearly set forth in the license and are in no way onerous.

The mining leases too may be granted by the local governments for periods of 30 years, but only under the condition that no one lessee, or those joint in interest with him, shall hold more than 10 square miles, the block not to exceed, without previous approval of the government of India, four times its breadth. To insert a renewal clause in a lease also requires the same approval.

As with prospecting licenses the conditions to be contained in the lease are specified besides which the local governments are allowed to add such stipulations and conditions as seems fit.

In buying an air compressor, S. K. Paterson (*Min. Sci.*, Jan. 7, 1909) recommends the purchase, other things being equal, of the compressor that gives the desired capacity at the slowest speed. This should be done even at a somewhat greater first cost so that the air capacity can be increased considerably whenever desired by simply increasing the speed at which the compressor is run. This is an extension of a principle used in Cornish pump design.

January Dividends

The accompanying table shows the dividends paid in January, 1909, by mining and industrial companies in the United States and by some foreign mining companies:

U. S. Mining Companies.	Location.	Amt. per Share.	Amt. Paid.
Alaska Mexican.	Alaska	\$0.40	\$72,000
Alaska Treadwell.	Alaska	0.75	150,000
Alaska United.	Alaska	0.25	45,000
Am. Smg. & Ref. com.	U. S.	1.00	500,000
Am. Smg. & Ref. pfd.	U. S.	1.75	\$75,000
Anaconda.....	Mont.	0.50	600,000
Boston & Mont.	Mont.	3.00	450,000
Bunker Hill & Sullivan.	Idaho	0.25	75,000
Colorado.....	Colo.	0.08	80,000
Copper Range.	Mich.	1.00	\$84,185
Federal, M. & S. com.	Idaho	1.50	90,000

United Metals Selling.	U. S.	5.00	250,000
Va.-Car. Chem. pfd.	U. S.	2.00	360,000
Total.....			\$1,860,131

At Broken Hill Proprietary mine, Australia, 10x10-in. sills are used for the drift sets in soft ground and 4x10-in. sills in hard ground.

Australasian Gold Production

Advance statements cabled from Australia give the gold production of the several States for the year; the figures varying but slightly from the estimates made by our correspondent, and published in the JOURNAL of Jan. 9. Any further changes made by the final returns will be slight. In the following table the figures are given in fine ounces, the comparison being with the corrected returns for the previous year:

	1907.	1908.	Changes.
W. Australia...	1,697,554	1,648,505 D.	49,049
Victoria...	695,376	676,061 D.	19,315
Queensland...	465,882	461,359 D.	4,523
New S. Wales...	247,363	224,792 D.	22,571
Tasmania...	65,355	60,453 D.	4,902
S. Australia...	10,651	14,500 L.	3,849
Commonwealth...	3,182,381	3,085,610 D.	96,771
N. Zealand...	477,312	472,095 D.	5,217
Total...	3,659,693	3,557,705 D.	101,988
Value...	\$75,645,854	\$73,537,762 D.	\$2,108,092

The returns for South Australia include the gold from the Northern Territory, which is attached to that State for administration purposes.

The total gold production of Australasia was, therefore, less in 1908 than in 1907 by \$2,108,092, or 2.8 per cent. The causes for the changes have been recently explained. The figures show that gold mining in Australia last year very nearly held its own, and is apparently recovering from the depression of the previous year.

Saddle Reefs of Bendigo, Australia

The ore at Bendigo, Victoria, Australia, occurs in saddle reefs which are simply bedded veins that occur along anticlinal folds and which "peter out" on the legs of the anticlines. These saddle reefs extend longitudinally for a great distance, being traced by the headframes along them for miles. There are three main lines of saddle reefs, according to Donald Clark (*Aust. Min. Stand.*, Nov. 18, 1908). The New Chum line is five miles long. Sometimes several reefs occur one above the other separated by varying distances of barren rock. The centers of each of these saddles is farther east than that of the one above. The deepest one of these reefs that contains pay ore is the one found at a depth of 4124 ft. in the Victoria Quartz mine. Vein material containing gold, but not in paying quantity, has been struck in this mine at a depth of 4525 ft. in a crosscut from the bottom of a winze from the 4254-ft. level. This is the deepest known occurrence of gold in the world.

New Stack of the Boston & Montana Company

The program of the 22d annual meeting of the Montana Society of Engineers, held at Great Falls, Mont., contains a new photograph of the great Custodis stack of the Boston & Montana company, recently described in the JOURNAL. The accom-

Rhodesian Mines

The gold production of Rhodesia in December is reported at 51,637 oz., making the total for the year 607,015 oz. Comparisons by quantities cannot be made with the previous year, since the reports in 1908 were made chiefly in fine gold, while in 1907 they were in bullion. By values the total for the year was \$10,603,-

NEW AND OLD STACKS, GREAT FALLS SMELTER, MONTANA

panying reproduction shows a comparison in size with the old chimney even more striking than that which appeared in earlier photographs.

The amount of ore mixture that can be run over a water-jacketed steel connection-spout on a copper blast furnace is approximately 25,000 tons.

907 in 1907, and \$12,293,234 in 1908; an increase of \$1,687,327 last year.

Other metal production reported in the month of December included 22,349 oz. silver, 69 tons lead and 10 tons copper. Ores reported were 4081 tons chrome ore, 6 tons wolframite and 3 tons scheelite. The asbestos mined was 18 tons. The coal production from the Wankie mines was 18,094 tons.

Personals

Herbert C. Hoover will be in New York about the middle of February.

G. W. Maynard, of New York, is recovering from a serious illness.

H. B. Pulsifer is at his permanent address, 817 Oak street, Kansas City, Missouri.

Mark R. Lamb is now with the Allis-Chalmers Company at Milwaukee, Wisconsin.

Carl F. Dietz, having finished his work at Parral, Mexico, has gone to Magdalena, New Mexico.

E. McCormick, of Calumet, Mich., is examining copper properties in the Northwest for local clients.

J. W. Mercer has returned from Ecuador, where he has been since last October. He will in a few days start on a trip to the West.

R. V. Norris, of Wilkes-Barre, Penn., has been delivering a course of lectures on coal-mining to the students of Harvard University.

Alfred R. Glancy, general superintendent of the Juragua Iron Company, Cuba, sailed from New York Jan. 29, for Santiago de Cuba.

Willard S. Morse has not resigned from the American Smelting and Refining Company, the previous report to that effect being incorrect.

E. G. Smith has been appointed superintendent of the Westmoreland Coal Company in Pennsylvania, succeeding B. F. Jones, deceased.

T. Lane Carter, of Johannesburg, Transvaal, is examining mines in Nicaragua. His address is care American Consul, Bluefields, Nicaragua.

J. H. Susmann has resigned his position as treasurer of the Tennessee Copper Company, and Walter Lewisohn has been elected in his place.

J. B. Tyrrell, Toronto, Ont., has been chosen a corresponding member of the council of the Institution of Mining and Metallurgy, London.

Thomas L. Lewis has been reelected president of the United Mine Workers of America by a decided majority over his opponent, John H. Walker, of Illinois.

Henry M. Adkinson, manager for the Gold Pioneer Company at Telluride, Colo., has returned to Denver from a business trip to the East of six weeks' duration.

Herbert Haas has resigned his position as manager of the mining department of the Union Iron Works Company, San Francisco, and will resume practice as a consulting engineer.

Frank Dunbar, recently superintendent of the Gallatin mine of the Monongahela River Consolidated Company, has been ap-

pointed general manager of the Sesser Coal Company's mines at Sesser, Illinois.

Frank A. Keith has resigned his position as general manager of the Tonopah Mining Company, of Nevada, and has opened an office as mining engineer in the First National Bank building, San Francisco.

Percy E. Barbour is at Minas Nuevas, Sonora, Mexico, where he is engaged with A. J. Yeager, the general manager, and W. M. Clark, the consulting engineer, upon the design of a 200-mill and cyanide plant for the Zambona Development Company.

H. F. de Bardeleben, Jr., has resigned his position as superintendent of the Woodstock Iron Company, at Anniston, Ala., to enter business with his father, H. F. de Bardeleben, Sr., of Birmingham, Ala., who has large holdings of mineral lands and is one of the pioneers of the district.

R. Y. Williams, who has been a member of the staff of engineers conducting the work at the United States Geological Survey station at Pittsburgh, has been transferred to Urbana, Ill., where he will have charge of the Survey's substation, established to disseminate knowledge of mine-rescue work.

H. Hunter, of London, who have been engaged in examining mines in Japan for seven months past, sailed from Kobe Dec. 31. He will spend some time examining tin mines in the Straits Settlements, and also the new tinfields in Siamese Malay and Burma, and expects to reach London about the end of May.

Ladd & Baker, Incorporated, is the name of a corporation formed to conduct a practice as consulting, metallurgical and contracting engineers, with offices in the Real Estate Trust building, Philadelphia. The officers are James B. Ladd, president; David Baker, vice-president; Francis H. Easby, treasurer.

F. R. Wadleigh, for 12 years chief inspector and fuel engineer for Castner, Curran & Bullitt, has been appointed assistant general manager of the Chesapeake & Ohio Coal and Coke Company, with headquarters in New York. Mr. Wadleigh will act as chief inspector and fuel engineer for the company, and will have charge of the inspection, preparation and use of its coal.

Obituary

John Cadejan died in Bridgeport, N. S., Jan. 20, aged 51 years. He was born in Nova Scotia and worked for a number of years as a coal miner and foreman. For eight years past he had been mine inspector for the Cape Breton district.

Edward L. Fuller, known as a large operator of salt mines and works, and also through his successful formation of the

International Salt Company, died of apoplexy Jan. 29, at Augusta, Ga., where he went for his health. He was 57 years old. He was president of the Retsof Mining Company, Empire Limestone Company, and a director of the Western Railroad Mining Company. He was a member of several New York Clubs.

Thomas Jones died of apoplexy at his home in Neodesha, Kan., Jan. 11, aged 68 years. Mr. Jones worked in the zinc smelters at Swansea, Wales, from his boyhood until 1867, when he engaged with Mr. Siemens in the steel business and in 1869 was employed by the German government to operate Siemens furnaces in connection with some steel works in Germany. In 1872 he came to the United States and superintended the construction of steel works near Providence, R. I. Following this he engaged in the manufacture of spelter near Providence, from dross and other waste from works in Massachusetts and the Connecticut valley. About 1879 he bought, through a broker, some ore from Virginia and, recognizing its excellent quality, located the mine in Wythe county, Va. In 1880 he, with others whom he had interested in the project, went to Virginia, bought the mine and built a smelting plant at Martin's Station (now Pulaski City, Va.) organizing the Bertha Zinc Company. This plant is still running, and is known as the Bertha Mineral Company. Mr. Jones operated these works until 1893, when he built another zinc-smelting plant at Pulaski, Va. This venture was short-lived. In 1896 he went to Sandoval, Ill., and built a small zinc plant which is still running as the Sandoval Zinc Company. In 1902 he went to Canada and succeeded in interesting the miners of that country in saving their zinc products, and in 1904 was engaged as works manager to build a zinc plant at Frank, Alberta. This plant was never completed. He was also connected with mine development work in Arkansas and Colorado at various times. Mr. Jones leaves a wife and six children. Three of his four sons are engaged in metallurgical work: T. J. Jones, superintendent of the Mountain Copper Company at Keswick and Iron Mountain, in Shasta county, Cal.; D. A. Jones, accountant for the Granby Mining and Smelting Company at Neodesha, Kan. and Archibald Jones, superintendent of the Prime Western Spelter Company's plants at Iola and Gas, Kansas.

Societies and Technical Schools

Rocky Mountain Club—At the annual meeting, Jan. 12, John Hays Hammond was elected president. The club is now planning to build a house of its own. Editors of all Western papers are invited to become guests of the club at any time while visiting New York.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at
San Francisco, Butte, Salt Lake City, Denver and London

REVIEWS OF IMPORTANT EVENTS

San Francisco

Jan. 27.—Weather conditions have not improved; the heavy rains continue and all the streams are overflowing their banks, causing floods in the valley sections and doing more or less damage in the mountain and foothill regions. A number of mines have had to cease all work except pumping. In all the mining sections of the State more or less damage is being done by the high waters and many power plants have been put out of business. Reservoirs have been carried away and ditches broken in all directions.

The legislative bill which appropriates \$400,000 for the improvement of the Sacramento, San Joaquin and Feather rivers to be spent in conjunction with a similar amount from the U. S. Government will probably pass without opposition. Considerable dredging will have to be done to improve those streams.

Joseph Weissbein and associates of San Francisco have obtained control of the Pittsburg, Gold Flat and Potosi Consolidated mines at Gold Flat, Nevada City district, and these mines will now be worked under consolidation through one large central shaft. A large plant will be installed.

Six miners were killed and several others injured in an explosion at the Stone Cañon Coal mines in Monterey county last week. This explosion comes just in time to aid the passage of the Rutherford bill pending in the legislature which provides for a State Inspector of Mines. When an affidavit is made by any three persons making complaint of the condition or management of any mine, then this inspector is to visit the property and make an examination and advocate such changes as he considers necessary and bring them to the attention of the management. Assemblyman Rutherford has also introduced a bill providing for the regulation of hours of labor for men who work underground and establishing an eight-hour day for miners. Senator Riley has also a measure, which is classed among the employers' liability measures.

The Forest Service will not include certain lands in the Tahoe and Plumas national forests until after further examination. This land embraces a strip from 10 to 30 miles wide from Forbestown, Butte county, to Placerville, El Dorado county, and is foothill land fit for agriculture and for mining purposes.

The California Liquid Asphalt Company is moving its plant from Summer-

land to Edna, San Luis Obispo county. The new refinery will have a capacity of 2500 tons per month. There is an abundance of heavy oil available at the new place. It is cheaper now to produce asphalt from the base of the heavy California oils than to mine the clear asphalt itself. As a result, most of the asphalt miners of the State have quit working. California asphaltum has to be shipped East on sailing vessels, as it will hardly bear railroad or steamship rates. There are very few vessels, however, sailing to New York from the California ports. The first one in a year was lately loaded at San Francisco. Large quantities of asphalt are being made into coke at the greater refineries at Point Richmond, on San Francisco bay.

A new corporation of local men has arranged to deliver water at any one of the four sidings of the Midway oilfield in Kern county at the rate of 5c. per barrel. The fact of the shipments being regular will be of great benefit to the oilmen of the district. Two 13-in. wells 680 ft. from the starting point of the Sunset line are the source of supply. The plant is equipped with both electric and steam power. The Midway oilfield has been held back by lack of water heretofore, and this new steady supply is of great benefit.

Salt Lake City

Jan. 29.—The Yampa smelter is treating more than 800 tons of Yampa ore per day; everything is working smoothly. The plant comprises nine McDougal furnaces, three reverberatories, three blast furnaces and a converter.

The Phoenix mill is treating 50 tons of Utah-Apex ore per day, and the Wall mill 50 tons per day. The Utah-Apex company is shipping from 50 to 60 tons of smelting ore per day. Connections with the Boston Consolidated railroad have been made, and ore can now be loaded directly into railroad cars.

Before Feb. 15 the United States company will add 1280 sacks to its bag house, making a total of 3380. The company's concentrating plant at Bingham Junction will probably be enlarged in the near future.

D. C. Jackling returned on Jan. 28 from a meeting of the Ray Consolidated Copper Company at Colorado Springs. At this meeting he was made general manager of the company; he will design a large concentrating plant and smelter to be erected at Kelvin, Ariz. Mr. Jackling states that the new position will not interfere in any

way with his management of the Utah Copper Company's properties.

On Jan. 27 the case of the Mammoth Mining Company vs. The Grand Central Mining Company came before the Supreme Court at Washington on a writ of error from the Supreme Court of Utah. The Grand Central brought action to recover \$300,000, the value of ore alleged to have been taken by the Mammoth company. The Grand Central won in the Utah court. The question involved is the right of the Mammoth company to follow a vein, the apex of which it is claimed was in Mammoth ground, to a point where it underlies the Silveropolis claim, the surface of which is owned by the Grand Central.

At Park City last week was the liveliest one in many months. At the Daly-West all energies are directed toward completing the drain tunnel, and making connections with the upper workings. The mine will soon be drained to a depth exceeding 2000 ft. At the Daly-Judge considerable work is being done, and connection between the McSorley and Daly drifts will shortly be effected. This will give the Bonanza Flat region a shorter outlet.

A drift on the 300-ft. level of the Little Bell at Park City has cut a body of rich carbonate and chloride ore. The ore-bodies of the Little Bell have been developed from the 400-ft. to the 700-ft. level.

The Uintah Treasure Hill Company has levied an assessment of 1c. per share. This will put \$10,000 in the treasury.

In reply to the opposition of the present management of the Daly-West Company, J. E. Bamberger, president of the company, states that no consolidation of the Daly-West with the Ontario company has been or is under consideration. The reason for suspension of dividends last year was on account of labor difficulties and low metal prices, but during the year extensive development was done in opening the mine at greater depth. This development is expected to show up large quantities of milling ore, and extensive additions to the mill are planned. He announced that the Daly-West company is now in first-class physical condition, well equipped, has no debt, has about \$300,000 in the treasury, and can resume dividends at an early date.

Grading work has commenced on the Tooele Valley railroad, which will connect the International Smelting and Refining Company's projected smelter with the Salt Lake route at Garfield and Tooele

city. Upon the completion of the line from Tooele, which will require about two months to build, building material will be shipped to the smelter site. Preliminary smelter plans are expected some time during February. The plant will have a capacity of 2000 tons a day and will cost from two to three million dollars.

The Conkling Mining Company has filed in the Federal court a suit of ejection against the Silver King Coalition Company; the plaintiff seeks an accounting for 20,000 to 25,000 tons of ore, valued at between \$800,000 and \$1,000,000 which the King company is alleged to have extracted from Conkling ground. The Silver King Coalition Company is again loading ore, and shipments will be resumed at once. The Miners Smelting Company, a Heinze concern, had a contract with the Silver King company which went into effect Jan. 1. Under this the King ore was to be treated at the Milford plant of Heinze's company, but it is said that an agreement has been reached under which the ore will be shipped to the Murray smelter.

For the week ending Jan. 14, the mines of Tintic shipped 76 thirty-ton cars of ore and 89 twenty-ton cars. The Tintic Smelting Company shipped 5600 bars of bullion.

The Colorado mine shipped 51 twenty-ton cars; Black Jack, 5; Brooklyn, 5; Beck Tunnel, 8; Dragon Iron, 22; Mammoth, 1 car. The Bullion Beck mine shipped 2 thirty-ton cars; Centennial Eureka, 42; Eureka Hill, 1; Iron Blossom, 2; May Day, 4; Ridge & Valley, 2; Sioux Consolidated, 14; Uncle Sam Consolidated, 4; Yankee Consolidated, 2 cars.

Butte

Jan. 28—The recent visit of H. G. Elliott, expert for the Pittsburgh Coal Company, to the coalfields near Great Falls, Cascade county, is thought to be the forerunner of active participation by the company in operations in that part of the State.

In the contest of the Government against the British-Butte company, preventing the issuance of the patent to the company for its placer claims at Rocker, five miles west of Butte, the acting receiver and register have rendered their opinion in favor of the company, and recommend that the patents be issued. The contention of the Government was that the company had fraudulently applied for patent of the ground as placer when in fact the land was valuable only for its lode deposits, and also that the company failed to do the required \$500 worth of work on its claims.

Denver

Jan. 30—The great activity in the Boulder oilfield, which has been caused by the opening of the 300-bbl. well of the Inland

company, continues, and numbers of new wells for oil and gas will be put down at once.

Mining operations in the Silverton, Telluride, Ouray and other districts of the San Juan region have been greatly hampered by snow slides during the recent storms. Railways are blocked in places, and may remain so for weeks, as the avalanches have packed the snow so tightly that the rotary plows are powerless to cut through it. Telegraph, telephone and power lines are down, the coal supply is cut off from many towns, and general discomfort prevails. At Telluride the Liberty Bell mine is said to be producing 10,000 tons per month of \$8 and \$10 ore, with reserves sufficient to keep the mill running for 15 years.

In the Cripple Creek district, the Vindicator Consolidated Gold Mining Company has issued its report for 1908, showing proceeds, after deducting freight and treatment, of about \$712,000, of which lessees received \$161,567; total cash balance after paying \$225,000 dividends in 1908, \$78,814. This company has paid dividends of nearly \$2,000,000.

Indianapolis

Feb. 1—The irregular condition of the Indiana coalfield was suddenly interrupted by an increased number of orders for coal due to a spell of genuine zero weather which broke over the central States the latter part of the week. The local dealers had permitted stock to run low.

The action brought by the Vandalia Coal Company against 18 coal miners who received injuries by an explosion in the Rosebud mine in Vigo county, to prevent them from maintaining separate suits at law to recover damages and to compel all of them to prosecute their claims in one proceeding in equity, has been decided adversely to the company by the Appellate Court, which held that a bill of peace cannot be maintained to prevent a multiplicity of suits in such a case.

A bill has been introduced in the Indiana legislature to prohibit employers of miners and other labor from taking out indemnity insurance against judgments in case of injury or death of an employee. It is claimed that such security makes employers careless regarding the safety and welfare of employees.

London

Jan. 20—The gold output of the mines of the Witwatersrand district, Transvaal, during the month of December was announced as 637,853 fine oz. of gold. These figures, however, include about 36,000 oz. of reserve gold accumulated from previous months. The custom of holding gold reserves, still maintained by several companies detracts from the value of the

monthly statistics. The professed aim of the directors of the companies in keeping a gold reserve is to equalize the monthly outputs and to prevent the shareholders from being unduly elated or depressed with the fluctuating returns that might otherwise take place. The absurdity of the system is revealed at the end of the year when the average yield has been incorrectly estimated and a large balance of undeclared reserve gold remains. In the December return several of the mines have declared a surplus of from 2000 to 3000 oz. equivalent to 2 to 7 per cent. increase in the profits for the year. The profits earned during the 11 months January to November have been to this extent inaccurately reported. An extreme case is that of the Ferreira gold mine, which at the close of the year let loose as much as 12,330 oz. from the accumulated gold reserves, equal to £51,786. The average monthly profit reported for 11 months was £33,333, whereas in reality it was about £4310 more per month. Consequently the published monthly returns were about 8 per cent. below their actual value, and the shareholders, whose nerves the Rand directors take so much trouble to protect by their gold-reserve system, have to suffer a severe, though not unpleasant, shock in December.

It is well known that the profits shown on working account differ considerably from the profits distributed in dividends and the nearer such profits can be brought to the dividend the better pleased will the stockholder be. As an example of the discrepancy between the published profits and dividends the case of the Ferreira may again be noticed. This mine published profits for the year 1908 amounting to, in round figures, £400,000. A further profit, as mentioned above, in the shape of gold reserve, amounting to £51,786, was declared in December, making altogether a working profit of £451,786. The dividend declared was, however, only £285,000, namely, 300 per cent., on a capital of £95,000. Shareholders may well ask why so large a margin is being accumulated.

While on the subject of returns, it may be questioned whether the elaborate statistics, some of which as explained above, are inaccurate, are necessary. Every month each mine cables home the number of stamps, tube mills, tons, ounces won from the different processes; indeed, so many figures that it takes some time for a shareholder, interested in any mine, to pick out the figures he really wants, namely, the tons treated and the profit earned. The expense of all this cabling must be heavy as well as the preparation of the statistics. It is doubtful whether all this technical data is wanted monthly. At all events this much is certain: that if monthly reports were dropped and quarterly reports substituted, a considerable saving for the shareholders could be made.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Alabama

For a number of years the Tennessee Coal, Iron and Railroad Company and the Sloss-Sheffield Steel and Iron Company have been working convicts in some of their coal mines. This year three other companies have begun to operate with convict labor. The Red Feather Coal Company contracts with the State of Alabama for the hire of a number of convicts, who will be employed in getting out coal at the company's mine at Lucile, in Bibb county. The Bessemer Coal, Iron and Land Company has contracted for State convicts, who will be employed at one of the mines at Belle Ellen, in Bibb county. The Pratt Consolidated Coal Company has agreed to hire the county convicts from Jefferson, Tuscaloosa, Walker, Blount and Morgan counties. These men will be used at the company's coal mine at Banner, in Jefferson county.

A syndicate represented by Dr. G. B. Crowe has purchased a large tract of land at Bessemer from the Bessemer Coal, Iron and Land Company. It is announced that the improvements to be made will include 250 coke ovens, the coal for which will come from the Yolande and other mines now operated by Doctor Crowe; also two blast furnaces with a capacity of 250 tons each daily. An electric plant will be operated by the waste gases from the coke ovens. A brick plant will also be erected.

JEFFERSON COUNTY

Johns Coal Mine—At this mine, owned by the Tennessee Coal, Iron and Railroad Company, a coal washer of the bumping-table type is being put in by Heyl & Patterson, of Pittsburg, Penn. A thorough test of the washing system will be made.

Birmingham Coal and Iron Company—An explosion on Feb. 2 in slope No. 2 of the company's coal mine at Short Creek killed 17 men.

Arizona

GILA COUNTY

Arizona Commercial—Development work continues to open good orebodies. A 350-ton smelter will be erected next summer.

Superior & Globe—It is reported that this company plans to develop vigorously during the next few months.

PINAL COUNTY

Roy Consolidated—This company is to build a mill and smelter at Kelvin. The

first unit of the mill will be of 3000 tons daily capacity. Upward of 7,000,000 tons of 2 to 2½-per cent. ore is now said to be developed, which has been done chiefly by churn drilling.

California

AMADOR COUNTY

South Eureka—The North drift 500 ft. long on the 2700-ft. level has struck the same footwall and payshoot found on the 2500-ft. level. It forms a 20-ft. vein of milling ore.

BUTTE COUNTY

Big Blue Lead—Power lines have been installed and the arastre will be operated by electric power.

Mesilla Valley—This company, E. C. Wilson, superintendent, has acquired the old Flea Valley ditch so as to have its own water power. A bedrock tunnel is being run to intersect the old channel.

Cape Horn—This company is shipping gold bars.

CALAVERAS COUNTY

Angels—At this camp a shortage of water closed down most of the mines for some weeks. Now the rainfall has been so heavy that the mines are having more water than they want.

EL DORADO COUNTY

Gravel—Under management of T. G. Patton men are at work opening a large gravel property near Pacific, about three miles from the Prevolcanic property.

Greenwood Creek—At this place the company which is opening several quartz claims has struck good paying lodes on the Lipton No. 1, and also on the Dundee No. 1. The ore carries gold, silver and copper.

INYO COUNTY

Loretta—This mine, formerly the McAffee, at Eureka valley, 30 miles east of Big Pine, is being developed.

NEVADA COUNTY

Omega Placer—Work is about to be resumed on this mine at Omega.

Murchie—This company has shipped 60 tons of sulphides to the Selby smelter.

PLUMAS COUNTY

Greenville-Pacific—This company, W. S. Haskins, manager, has bonded the New York mine at Greenville from J. D.

Whitney. A 400-ft. tunnel is expected to open up valuable oreshoots.

SAN LUIS OBISPO COUNTY

Hamilton Quicksilver Mine—A large deposit of cinnabar ore has been struck in this mine on San Simeon creek, near Cambria. Work has been prosecuted on the property for two years, hitherto without much success.

SHASTA COUNTY

Minnie Shasta—This company has made its last payment of the purchase price of \$20,000 for the Bracket quartz mine, four miles west of Redding.

Hazel—In the Gladstone mine of this company, at French Gulch the vein found on the 600 level is wide and rich.

SIERRA COUNTY

Bonanza King—From this mine at Alleghany, E. H. Wilson manager, very rich quartz is now being taken. The vein is about two feet wide. Another tunnel will shortly be run.

Twenty-One—This mine, a continuation of the Rainbow at Alleghany, has been placed under bond to C. C. Cray representing eastern men. Development work has commenced.

SISKIYOU COUNTY

A new company has taken hold of the Foster & McIntosh quartz mines near Calahan, and men have been set at work.

SONORA COUNTY

Culver-Boer Quicksilver Mining Company—This company, of Cloverdale, intends to erect a 40-ton Scott furnace.

TRINITY COUNTY

Trinity Gold and Milling Company—For loosening up ground at this hydraulic mine at Minersville, 15 tons of powder were exploded simultaneously in four blasts. A 300-ft. tunnel was run into the gravel and from this were run drifts to contain powder.

TUOLUMNE COUNTY

C. W. Wagner and W. C. Bowman are opening a copper mine at Chinese. Some gold is found in the ore.

Imperial—This group near Jacksonville has been bonded to San Luis Obispo county men and the mines are to be worked on a large scale.

Central Mother Lode—At this property, J. P. Mangante, superintendent, a two-

compartment shaft has been started to be sunk 200 ft. before drifting is commenced. An engine and hoist are shortly to be installed and later a ten-stamp mill will be put up.

Nerri Gold Mining Company—This company has secured options on the purchase of the Galena and Buckeye mines near Italian Bar for \$30,000. Miss F. M. Colby is president and general manager of the company.

Option—Plemon, Vieira & Lind have taken an option on 400 acres of patented land owned by A. Bonavio on which mining will commence at once; 25 per cent. of the net proceeds of the returns are to be paid to the owner of the ranch.

Colorado

LAKE COUNTY—LEADVILLE

Dinero Tunnel—Work has been resumed on this property, Sugar Loaf, and the upraise, to connect with the old shaft, is being pushed. When this connection is made attention will be turned to developing the large body of ore at the breast of the tunnel.

Yak Tunnel—Four drill holes have penetrated the water in Resurrection No. 1 shaft, and the water in that property is being lowered at the rate of 5 ft. per day. Four more drill holes will be drilled and it is expected that the bottom of the shaft will be seen within 30 days. In the meantime the water pouring into the tunnel will be piped, and when this is completed the work of driving ahead will be resumed.

Alps Group—This property, head of South Evans gulch, is under lease to James Kavanaugh and associates. A shaft is being sunk.

Cleveland Shaft—The management of this property, South Evans, has decided to sink this shaft 200 ft. instead of 100 ft. as first intended. When the work is completed the shaft will be 825 ft. deep.

Tribune—This property, Breece hill, is worked from the Yak tunnel by a drift following a small streak of ore high in gold; it is expected that in another 30 ft. an ore shoot from the lbex will be caught.

Belvidere Tunnel—This bore, Horseshoe district, is in 400 ft. and the orebody shows up well. On account of the heavy snows the ore is piled on the dump. With the disappearance of the snow connections will be made with the Chance-Hilltop tramway, which will facilitate the handling of the ore.

Little Bertha—This property, Breece hill, is under lease to J. B. McDonald, who has sunk the shaft to 225 ft. and from this point with drifts north and south opened a body of gold ore. The property adjoins the President.

Chrysolite—In this mine, Fryer hill, a fair body of lead ore has been opened at

the lower level and shipments are being sent. The mine is also producing some excellent iron.

Great West—A tunnel has been driven on this mine, Bucksin gulch, for 200 ft. on a fissure vein that averages in width 4 ft., carrying gold, silver, lead and zinc; several shipments have been made from the vein giving returns of \$600 per ton. The tunnel will be driven 300 ft. farther into the hill, so as to drain the ground; then stoping will be started. The property is being worked by Leadville men.

Result—This mine, Carbonate hill, is owned by the Small Hopes Company, and recently a promising body of oxidized iron carrying 18 oz. silver to the ton was opened in the lower workings; the body has been developed for 20 ft., and at the breast is 12 ft. long and 6 ft. thick. Shipments have been started.

Shamus O'Brien—This mine, Yankee hill, is being worked at the lower levels by lessees, and recently they opened a 4-ft. body of ore that runs well in silver and lead; in addition to this there is some low-grade ore; shipments are going out weekly.

Vinnie—Some rich gold ore is being taken from this mine, Breece hill, while from the main orebody regular shipments are going to the smelter.

TELLER COUNTY—CRIPPLE CREEK

Drainage Tunnel—At the annual meeting of the stockholders of the tunnel company the following directors were elected: F. G. Peck, Sherwood Aldrich, A. E. Carleton, F. F. Castello, F. J. Campbell, C. C. Hamlin, J. T. Miliken, William Lenox and A. L. Burris. The old board was re-elected with the exception of S. S. Bernard who was succeeded by A. L. Burris. The annual report of the treasurer shows that of the \$388,500 subscribed for driving the tunnel \$175,000 is still due. Cash on hand \$23,820 with all the work paid for up to Jan. 1, 1909. This gives about \$200,000 for the work and it is estimated that it will take about \$120,000 more to complete the work. At present work is pushed at both the portal entrance and the intermediate shaft. The work is done under contract by A. E. Carleton, of Cripple Creek.

Wish Bone Mill—Additional machinery is being put in place at this mill which is situated on the north side of Mineral hill. Surveys are also being made for a railroad from the main part of the district to this mill. The road will be run from Hoosier Pass and will be of standard gage. The mill was originally built to treat ore on the ground but for some reason no ore was ever put through and the management has decided to handle custom ore, for which purpose the railroad is being constructed.

Cripple Creek & Colorado—The shaft house on the property, usually known as

the Rittenhouse property, was burned this week and was almost a total loss. The shaft house was equipped with a fine plant of machinery and, it is understood will be rebuilt at once. The property is worked under lease by W. A. Birdsall, of Cripple Creek.

Gold Coin—This company has declared a dividend of 2c. per share amounting to \$20,000.

Idaho

SHOSHONE COUNTY

Alice—About \$1,000,000 worth of ore has been blocked out and an official states that work will commence within the next 60 days on a new concentrator.

Success—Work will be resumed on this zinc property about the beginning of April. A force of about 100 men will be employed in both the mine and mill.

Copper Plate—A report issued to the stockholders states that about \$7000 worth of work was done last year, bringing the total development to about 2200 feet.

Oreano—A financial statement by the secretary shows that, in 1908, \$3000 was spent on the property, mainly from assessments on capital stock. Another assessment has been levied for continuing development work.

Ajax—The force of workmen has been doubled and the long drift tunnel has been driven about 1600 feet.

H. E. M.—A contract for 400 ft. of work has been let.

Tiger—A large area of the upper workings caved in, but no damage was done. The property was recently abandoned by the Federal Mining and Smelting Company and had just been dismantled of machinery. Some ore is still shipped under lease.

Black Horse—The ore recently encountered has widened to about 7 ft., practically all of shipping grade.

BOISE COUNTY

Columbia Mining Company—A concentrator has been added to the Last Chance mill. Work will be started on material from the new orebodies recently uncovered.

Gold Hill & Iowa Mines Company—The upper levels are worked by lease. Plans are being made to drive all machinery electrically. For this purpose the new power line will be extended from Centerville, where it will tap the main line from the Payette dam.

Indiana

DAVIES COUNTY

The Indiana-Kelly Coal Company has leased 740 acres of coal land a few miles south of Washington, and will develop the territory. A few Washington capitalists

are interested. The company is also making an investigation of a newly discovered block coalfield in Fountain county.

VERMILION COUNTY

The Clinton Coal Company has purchased for \$20,000 a tract of 574 acres of coal land west of Clinton. The company is one of three operating in the Clinton field. It now has the Crown Hill mines 1, 2 and 3, and proposes to open mines on the newly acquired land. The Deering Coal Company, which has eight mines in this field, is preparing to sink additional shafts west of Clinton.

Michigan

COPPER

Calumet & Hecla—In the Federal Court at Cincinnati on Feb. 2 the appeal of Charles Bigelow, president of the Osceola Consolidated Mining Company, from the decision of the Circuit Court of Western Michigan in Bigelow's case against the Calumet & Hecla company was refused. The Calumet & Hecla company is in control of the voting power of the majority of the Osceola company's stock, and at the last annual meeting placed directors in office who were opposed by Bigelow and the stockholders represented by him. In his suit brought in Michigan Bigelow alleged that the control of the Osceola company's votes by the Calumet & Hecla company was a violation of the interstate commerce act. The Court of Appeals holds that there is no violation. Bigelow will carry the case to the Supreme Court.

Obijway—No. 2 shaft has reached the 3d or 650-ft. level, and a crosscut has been started to cut the lode, which in all probability will be reached within a week. The lode when opened in the level above was about 14 ft. wide and well charged with copper, being a decided improvement over the showing on the 1st level. No. 1 shaft is approaching this same depth. The shaft has not cut the footwall below the 500-ft. level, but it will not be necessary to crosscut very far to reach it. The lode opened at the 1st or 500-ft. level of this shaft was in two beds, about 20 ft. and 13 ft. wide, respectively, and separated by about 15 ft. of trap rock.

Atlantic—Section 16 shaft is being sunk below the 2000-ft. mark. The rock passed through is much shattered. The lode, intersected by the crosscut from the 15th level about 400 ft. west of the shaft, is strong and may be the much sought Baltic lode.

Wyandot—Another copper-bearing lode has been found in the crosscut driven from the 700-ft. level of the exploratory shaft. Drilling on this find will soon begin. About 100 ft. of drifting has been done on the lode first found; the breasts of both drifts consist primarily of epidote well charged with heavy stamp and barrel

copper. This has been the most important development in the history of the company and gives promise of good results.

Adventure—This company has discontinued the two vertical diamond-drill holes and with the aid of this additional data, is now drilling another on the approximate pitch of the formation.

Superior—The second mill gave even better results than did the first. After a few minor alterations have been made, regular shipments will begin.

Missouri

JOPLIN—ZINC-LEAD DISTRICT

Lizzie D—This company will erect a 200-ton mill on the Malang land at Peacock. It has a 15-acre lease with a shaft and three drill holes showing a 15-ft. face of ore at 192 feet.

Microbe—This company, of Joplin, has been incorporated with a capital stock of \$50,000 to operate a mine at Spring City. Adam Scott, of Joplin and Kansas City and Abilene, Kan., men, are the stockholders.

Continental Zinc—This company is replacing the balanced skips in the double-compartment shaft at Prosperity, with balanced self-dumping cages. With the old arrangement the water has to be kept about 30 ft. below the drift. Large cars will be used in the mine and mules to haul to the shaft.

Cameron—This company at Sarcoxie will complete its 250-ton mill about Feb. 15.

Katherine D.—This company is preparing to sink a shaft on its 30-acre lease on the Gray land southwest of Joplin. Two drill holes show rich ore. George Pearson, of Joplin, is superintendent.

Montana

BUTTE DISTRICT

British-Butte—The new gold dredge will be put in operation on Jan. 30. Invitations to witness the event have been issued to prominent mining men and State officials.

Butte Hill Copper Company—At the annual meeting of stockholders held Jan. 23, the following were elected directors: Maurice Eisenberg, H. A. Frank, J. W. Murphy, Duncan MacRea, W. P. Cary, W. H. Hall, Thomas Driscoll, James Higgins and John F. Davies.

Columbia-Butte Mining Company—A petition for permission to change the company's name to Columbia-Butte Gold Mining Company has been filed in the local district court. It is stated that the word "Gold" was omitted by mistake.

BROADWATER COUNTY

Keating Gold Mining Company—Jesse

B. Root, president, is now in New York for the purpose of placing the stock on the curb. The management states that shipments are being made at the rate of about 65 tons per day and that the ore is giving a net return of \$5.50 per ton after all expenses are paid.

MADISON COUNTY

Fortune Group—Richard T. Cook and Alfred T. Cook are working a force of men on the claims, located about five miles west of Virginia City. At a point about 300 ft. from the mouth of the tunnel on the Fortune claim a crosscut is being driven.

MISSOULA COUNTY

Kennedy Creek Coal and Coke Company—The company was incorporated a short time ago by John A. Scott, T. C. Marshall, W. J. Rhoades and Frank Thomas, of Missoula, and W. C. Edwards, of St. Paul. Its properties are located on Kennedy creek, near Stark, and when the transfers are completed will comprise about 700 acres of coal lands.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Portland Florence Lease—A vein of milling ore was recently opened on the 400-ft. level. Crosscuts are being driven on the 200-ft. and 300-ft. levels to intercept the Combination Fraction vein. This lease was formerly the Nevada Leasing Company's ground and adjoins the old Reilly lease.

Commonwealth Leasing and Mining Company—A shipment of 16 tons was made last week from this property. All this ore came from a shallow shaft. At a depth of 100 ft. several stringers have been found in the shaft, which although narrow, are rich.

Daisy Florence Lease—The four inches of rich ore that was found last week in the stope from the 200-ft. level has now widened to 2 ft. of shipping ore.

Matilda Lease—This company, leasing on the Atlanta property, is re-timbering its shaft between the 200-ft. and 300-ft. levels preparatory to sinking. A large vein was found in the drift on the 250-ft. level, but did not contain pay ore; exploration work will be carried on at greater depth.

February Premier Lease—This company, operating on the February claim of the Goldfield Consolidated, has its shaft down below 400 ft. and will continue sinking until a depth of 500 ft. is reached; then crosscuts will be run east and west to the limits of the ground.

Goldfield Star Mining and Leasing Company—The shaft on the Minnevade Fraction of the Lone Star company is 250 ft. deep. In a crosscut on the 150-ft. level

the footwall of the Lone Star vein has been cut. On the 250-ft. level a crosscut has been started to intercept the vein underneath the underhand stope, from which the Patrick lease was extracting ore at the time of the forfeiture of the lease for underhand stoping.

Goldfield Golden Pick—The shaft at this lease on the Pipe Dream lode has reached a depth of 350 ft., and is the deepest shaft on the Silver Pick property. A crosscut on the 250-ft. level disclosed a vein $4\frac{1}{2}$ ft. wide carrying some gold. Work will be pushed in this crosscut, as well as on a new vein just found in the station cut on the 350-ft. level.

Goldfield Merger Mines Company—A crosscut is being driven on this property from the 600-ft. level to cut the St. Ives vein. Good ore has been found in several places.

Mohawk Ledge—This lease on the Jumbo Extension, which was granted an extension of 221 days on account of the litigation last summer between the Jumbo Extension and Goldfield Consolidated companies, resumed shipments last week. The lease does not expire until the middle of March.

C. O. D. Consolidated—The orebody between the Gold Bar and Victor claims continues to improve. A crosscut is being run from the 300-ft. level to intercept the shoot at that depth. In a drift from the bottom of the winze, 30 ft. below the 200-ft. level, the ore, 4 ft. wide, continues to be of good grade. For the last two years this orebody has been known to exist and shipments amounting to \$30,000 were made from it, but work was not resumed until a consolidation securing the Victor claim was effected.

Little Florence—The annual meeting of this company was held in Phoenix, Ariz., Jan. 18. George Vickers, of Goldfield, was elected a director to succeed James E. Keelyn. The larger holders at the meeting assessed themselves so as to continue work in the lease on the Combination Fraction ground. The three-compartment shaft is now 500 ft. deep; the different levels will be prospected.

ESMERALDA COUNTY—RAWHIDE

Murray Lease—On the 200-ft. level the rich high-grade ore recently struck is 2 ft. wide; through the high-grade ore small seams of native gold are seen. On this level about 75 ft. of drifting have been done. On the 100-ft. level the vein averages 7 ft. in width, and the ore is of milling grade. On the 80-ft. level the vein is also 7 ft. wide, but the ore is slightly richer.

Kerns No. 1 Lease—At this lease, owned by George F. Von Polenz and associates, on the Rawhide Queen property, some exceedingly rich ore has been developed. Last week two shifts were put on; about 15 men are working at this property.

Holland Rickard Lease—Some rich stringers of gold ore have lately been struck in this lease on the Coalition ground.

Daisy—At this property on the east side of Ballon Hill, a 4-ft. vein of good ore was recently struck.

Gregory Mining District—This is a new district opened up about 14 miles southwest of Fallon. The veins are large; the country rock appears to be an andesite, and from all appearance the district resembles Goldfield both topographically and geologically. Many claims have been located.

ESMERALDA COUNTY—BOVARD

Bovard Strike Mining Company—This property has been developed by a tunnel which is in fine milling ore. The Bovard district lies about 18 miles southeast of Rawhide.

HUMBOLDT COUNTY—SEVEN TROUGHS

Harris Lease—Ore of exceptionally good grade has been found in the winze from the 200-ft. level. High-grade milling ore has also been opened up in the raise from the same level. A shipment is about to be made to the Kindergarten mill.

Reagen Lease—High-grade ore is being broken at several places in this property; in a drift from the raise on the 200-ft. level 2 ft. of shipping ore was recently opened.

English-George Lease—The ore being extracted from this property and now treated at the company's new mill is said to assay between \$50 and \$60 per ton.

Cleghorn-Duke Leases—The management of these leases on the property of Seven Troughs Signal Peak Mining Company and of the Seven Troughs Consolidated Mining Company, has recently purchased a $2\frac{1}{4}$ -in. machine drill, air compressor, and two gasolene engines of 25- and 10-h.p. The equipment has been received at Lovelock and will be installed at once. The tunnel which is to be driven to develop these leases is already 400 ft. long, and will be rapidly pushed to a length of 1500 ft. so as to open the vein at considerable depth.

Wihuja Lease—On Jan. 14 the drift on the 340-ft. level broke into the oreshoot; 18 in. of this vein shows some of the richest specimens ever taken out of the property. The shoot is the same as that opened on the 265-ft. level; the ore will be stoped from the 340-ft. level. Preparations are being made for another mill run.

LINCOLN COUNTY—PIOCHE

Finsen Ray-Black Wonder—A syndicate composed of Pioche and Salt Lake City mining men recently purchased the Finsen Ray mine the price is said to be \$60,000. The Black Wonder, an adjacent

property also changed hands. It is reported that a consolidation of these two properties will be effected. The ore carries lead and silver together with a little gold.

Prince Consolidated—A station has been cut on the 550-ft. level, and a crosscut is being driven to the vein. Driving is also in progress on the 300- and 400-ft. levels.

Pioche King Mining Company—This company was recently incorporated at Goldfield, the capitalization being 1,000,000 shares having a par value of \$1. The ground that the company holds includes the Bullion-Belcher group of six claims, the Gladstone group of three claims and several other single claims. The ground surrounds the Prince Consolidated on the north, west and east. On completion of patent proceedings, now pending, a complete equipment will be installed and development work started.

NYE COUNTY—HELENA

Broken Hills—The last carload shipment of ore from this property brought \$122 per ton; the ore assayed \$77.60 gold and \$44.7 silver per ton. The ore was taken from the Ols shaft in which shows a vein carrying 3 ft. of high-grade ore. On account of the heavy expense of hauling, production is being curtailed until the completion of a mill which the company plans to build this spring.

Lease Block No. 16—A vein 3 ft. wide containing ore that equals in richness the Broken Hills ore was discovered last week in this lease.

NYE COUNTY—BULLFROG

Pioneer—Smelter returns on the last two carloads of ore shipped amounted to \$15,000 for the entire lot; one car of 40 tons, taken out during the earlier period of development, averaged a little more than \$100 per ton; the other car, sampling approximately \$220 per ton gave \$11,000. Another car was shipped Jan. 23 to Salt Lake City. Only the ore already broken is mined from the upper winze; all other work in the winze has stopped. Milling ore is showing in the breast of the drift on the 210-ft. level.

NYE COUNTY—HANNAPAH

Silver Gance—Shipments continue from the Conrad & Lain lease, the output being about one carload a week. The ore is being treated at the Belmont mill at Millers.

NYE COUNTY—TONOPAH

Belmont—The South vein, which was faulted on the 1000-ft. level was found again last week; the orebody is now 5 ft. wide in the face of the drift. On the 1100-ft. level a crosscut is being run to a point under the old Belmont shaft with which connection will be made for ventilation. The raise from the west drift on 1100-ft. level to the 1000-ft. level is

finished and was in ore the entire distance of 127 ft. on the dip of the vein. Production for the week ending Jan. 23 was 550 tons.

Montana—Drifts are being extended east and west from the crosscut on the 515-ft. level which recently cut the Triangle vein. Both drifts are in ore averaging 5 ft. in width. Stopping is being carried on from the 390-, 465- and 565-ft. levels. A raise has been started on the vein from the 615-ft. level to connect with the 515-ft. level, the ore showing a width of 2 ft. Production for the week was 750 tons.

Tonopah Mining Company—Work was resumed on Jan. 20 in the drill hole being run from the 740-ft. level of the Silver Top claim; the bottom of this hole is 260 ft. below the level. The 200-gal. electric pump, which is to be installed on the 1200-ft. level of the Mizpah shaft has been shipped, and a station is now being cut for it. When in operation, sinking will be continued to a depth of 1500 ft. During the week the mill treated 3000 tons of ore averaging \$23.60 per ton, and shipped 105 bars of bullion valued at \$87,150 and 22 tons of concentrates valued at \$9350.

Mogul Consolidated—This property, 10 miles north of Tonopah, recently made a shipment of 85 tons which returned \$31.85 per ton. The ore is a lead carbonate carrying gold and silver in a quartz gangue. The main shaft is 575 ft. deep; 20 men are working at the mine.

South Dakota

LAWRENCE COUNTY

Branch Mint Operating Company—The first clean-up from 1300 tons of dump ore was better than expected and the New York interests have ordered work to proceed. The gold extraction is about 80 per cent. and the mill is treating about 250 tons daily.

Homestake—A new and simpler valve system to regulate the water supply to the mills, has been installed. The company has also purchased the timber, tie and lumber pickling plant at Englewood from the Government and will treat its own timber by the creosote method.

Warren Peak—The Rochford owners have decided to build a mill to treat the ore which averages \$7 per ton gold.

PENNINGTON COUNTY

Standby—Supt. J. B. Baker, of Rochford, is planning to increase the stamps at the mill from 20 to 100 during the coming summer. Work on the property will resume as soon as the weather permits.

Mystic—A new hydraulic placer mining company has been organized by Thomas

Ormsby to operate on Castle creek among the early-day placer diggings.

Tennessee

POLK COUNTY

Tennessee Copper Company—Of the \$2,500,000 in cash that this company is to get from the Independent Fertilizer Company, \$875,000 has so far been received.

Utah

JUAB COUNTY

Tintic Utah Consolidated—A drift on the 300-ft. level is being run east of the shaft in the expectation of cutting the Humbug vein. The Utah Consolidated claims are situated north of the Sioux Consolidated and the Colorado company's properties.

East Tintic Development Company—On the 200-ft. level a cave 60 ft. long and from 10 to 25 ft. wide has been cut, carrying as much as 10 ft. of lead sulphide and carbonate. The ore does not run high in silver.

Yankee Consolidated—At the recent meeting the following officers were elected: J. E. Dubois, president; J. E. Frick, vice-president; B. M. Lehman, treasurer and general manager; A. E. Canfield, secretary. Last year 4800 ft. of development work was done. There is a surplus in the treasury, and drifting will be pushed on the 300-, 400-, 500-, 600- and 900-ft. levels.

Beck Tunnel—This company is searching for ore on the 1100-ft. level where the showing is promising.

Plutus—The Plutus and Tetro holdings were consolidated a short time ago, and operations at the property will be started early in February. Jesse Knight is president and David Evans general manager. The company owns 14 claims. Development work will proceed in both Tetro and Plutus ground.

Alaska

COPPER RIVER DISTRICT

It is announced that the Copper River railroad has been completed from Cordova to a point above the Abercrombie rapids on the Copper river, a distance of 54 miles. A wharf for handling heavy material has been provided and four steamers are to be built to develop the copper districts of Copper and Chitina rivers. Contracts have been let to extend the railroad up the Copper river toward Fairbanks.

Canada

ONTARIO-COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ending Jan. 23 were

as follows: Chambers-Ferland, 62,000 lb.; Kerr Lake 62,460; King Edward, 53,920; La Rose, 393,650; Nova Scotia, 410,390; Nipissing, 186,033; Peterson Lake, 81,560; Right of Way, 244,715; Temiskaming, 60,000; Temiskaming & Hudson Bay, 184,060. Total 1,369,788 pounds.

Cobalt Central—On the Bailey property operated under lease by this company some good finds have recently been made at 140 ft. from the Big Pete shaft on the first and second levels, and the same vein is showing up well at a depth of 180 feet.

Colonial—Development work has resulted in the discovery of large deposits of low-grade ore, with some of higher quality. Concentration has been decided on, and work is temporarily suspended while a stamp mill and concentrator are being installed.

ONTARIO—SOUTH LORRAIN

Harris-Lorrain Syndicate—This property adjoining the Wettlaufer has a force of 18 men at work. Altogether 24 veins have been opened and three shafts have been started. Machinery will be ordered before spring.

Mexico

CHIHUAHUA

Rio Plata—Manager D. W. Shanks' annual report to stockholders for the 11 months ending Nov. 30, 1908, contains the following items: Ore delivered to mill, 14,183 tons, of an average value of 90 oz. silver and total 1,296,470 oz.; shipping ore sorted, 90 tons of an average of 1502 oz. silver, and total 135,180 oz.; total stored in tailings pond on Nov. 30 of last year amounted to 14,616 tons containing 645,098 oz. silver. The total expenses are given as \$100,886, or \$7.113 per ton, and \$0.1382 per oz. silver recovered. The net profits for the period were \$248,608. The new cyanide plant will be in operation within three months.

International Gold Mines Company—This company is making ready its cyanide plant at the El Socorro mine in the Ocampo section for an extended experimental run on dump ores that are said to average \$20 gold and silver to the ton. It is the plan to start regular milling on mine ores by the first of May. Col. J. W. Pender is the manager in charge of operations for this Kansas City company.

Rio Tinto—This company's lately blown in smelter at Terrazas is turning out copper matte at the rate of about 12 tons daily. This output will be considerably increased as soon as minor difficulties at the works are overcome.

Laguna—Prospecting of an encouraging sort is carried on in a district west of Laguna, a station on the Mexican Central in the northern part of the state. The ores are mainly gold and silver-bearing copper and lead sulphides.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, Feb. 3.—The coal market in the West is reported as more active. Cold weather and storms throughout nearly all the western territory have stimulated sales and shipments of coal for domestic use. There is a little improvement in steam coal, but not to any marked degree. For the time being, however, dealers have enough to do to take care of domestic sales and are somewhat encouraged.

Coke shipments are showing a considerable increase, which is due to the greater activity at furnaces. There are more furnaces in blast now than for several months, while others are putting in stocks with the expectation of blowing in before long.

The Seaboard bituminous trade is quiet, sales of steam coal showing little improvement in the East. The anthracite trade is also quiet, but shipments continue fairly steady from the mines. It is still reported that much anthracite is going into stock as a provision against any contingencies which may arise next spring.

It was reported that the United States Supreme Court would this week give its decision on the appeal from the Circuit Court on the commodities clause of the Interstate Commerce law, which prohibits railroads from carrying coal which they own or mine. The Court, however, has adjourned for two weeks so that no decision will be handed down for that time. The Circuit Court, it will be remembered, decided that this clause of the law was unconstitutional.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to Jan. 25, 1908, and Jan. 23, 1909, in short tons:

	1908.	1909.	Changes.
Anthracite.....	353,966	302,763	D. 51,203
Bituminous.....	2,237,985	2,175,888	D. 62,097
Coke.....	467,999	639,545	I. 181,546
Total.....	3,049,950	3,118,196	I. 68,246

Average daily tonnage, 121,098 in 1908, and 135,574 in 1909; increase, 13,576 tons.

New York

ANTHRACITE

Feb. 3.—The cold wave from the West which reached New York this week, sending the thermometer down nearly to zero, gave a temporary lift to the retail trade. It has not yet, however, touched the wholesale business; whether it does or not depends upon how long it continues, which

at the present writing seems very uncertain. Otherwise there is no change from the dullness which has prevailed for some time.

Prices are unchanged. The list prices for prepared sizes are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points.

BITUMINOUS •

Business in soft coal is still very quiet, with irregular increases followed by quick decreases. The far East is not taking any more coal, but there is a little business along the Sound. New York harbor is still dull. There is no pressure to sell coal, however. Good grades of steam coal can be bought at \$2.40@2.50 and gas coal at \$2.25 for run-of-mine. Gas slack is still in some demand.

All-rail trade continues to be better than tidewater, though it is not extremely active. Cars are abundant but the railroads are taking matters quietly and are not pushing transportation.

In the Coastwise trade little is doing and rates are still pegged at about 75c. to around the Cape. The Department of Commerce and Labor has issued an order limiting the size of tows to three barges and the length of towing lines to 75 fathoms. This is the result of many complaints of the danger to navigation resulting from long tows. It may have the result of increasing Coastwise freight rates by barge.

Birmingham

Feb. 1.—The Alabama coal trade is not very active just now. A number of mines in this State have been running on short time; in fact a movement was started among the coal operators recently to curtail the production in order that the output might be held down to something near the demand. There has been no change as yet in coal prices. The loss of the Louisiana trade, which had come to the rescue of this district, is being felt.

The coke production is being maintained at the top notch. What coke is not being consumed immediately is being stacked, as the indications point to a need of the product. Coke prices remain firm.

Chicago

Feb. 1.—Another cold wave has stirred up the demand for domestic coals, and

sales have been brisk. The market is closely responsive at this stage of the winter to weather changes, but dealers and consumers seem to have concluded that the winter will be open but for an occasional cold wave, and cease buying as soon as the mercury ascends. Steam coals are less affected and the consumption of western steam grades is steady and probably is increasing slightly. Screenings, highly important in the steam trade, have become firmer and lump has weakened, in the last week. In the domestic trade the demand is largely for low-priced coals.

Illinois and Indiana lump sells for \$1.75 @ 2.55, run-of-mine for \$1.60@1.75 and screenings for \$1.35@1.60. Eastern coals continue sluggish partly because of the turning of consumers to lower-priced Western coals, and partly because of large shipments that depress the market. Smokeless continues in overabundance with run-of-mine selling for \$2.75@2.85 and lump at \$3.20@3.65, for Pocahontas and New River. Hocking is cut 25 or 30c. under the circular price of \$3.15 and has been in too large supply. Youghiogheey is quiet at \$3.15, movement being restricted to contracts, chiefly.

Anthracite is decidedly better as a result of the last cold wave, but was lifeless just before that. Retailers' bins are not holding any considerable supplies in city or country, but the wholesale supply is abundant and leads everybody to delay buying until the moment of need.

Pittsburg

Feb. 2.—Coal shipments to southern ports have stopped, as the rivers have fallen to below a barge stage. It is expected that the rivers will be navigable again before the end of the month. On this rise fully 10,000,000 bu. of coal were shipped. All the river mines are in operation, but the railroad mines are being run irregularly. One independent company is running at about 60 per cent. of capacity, but the general average of operations of railroad mines is not at more than 25 per cent. of normal production. Prices remain unchanged on the basis of \$1.15 a ton for mine-run coal at mines; slack continues around 75c. Some large transactions in slack are reported this week.

Connellsville Coke.—Coke prices for prompt shipment have declined and some low rates have been named. Sales of furnace coke for spot are reported at \$1.60 a ton and even less although a number of the large producers are holding

firmly at \$1.75 for spot and \$1.90@2 on contract. A number of plants have been closed and production is being curtailed by some producers who are running their works but five days a week. Foundry coke for spot shipment has dropped to \$2, but in some instances \$2.15 has been paid. On contracts for deliveries running through the first-half quotations are still \$2.25@2.40 at ovens. The *Courier* gives the production in both regions at 267,709 tons. The shipments amounted to 9825 cars as follows: To the Pittsburgh district, 3,497; to points west of Pittsburgh, 5,373; to points east of Connellsville, 955 cars.

Foreign Coal Trade

Nova Scotia Coal—Coal shipments from Nova Scotia mines, year ended Dec. 31, long tons:

Company:	1907.	1908.	Changes.
Dominion.....	3,193,000	3,199,000	I. 6,000
Nova Scotia Steel.....	623,162	644,338	I. 21,176
Cumberland.....	276,549	362,339	I. 85,790
Acadia.....	321,192	320,122	D. 1,070
Inverness.....	243,075	256,910	I. 13,835
Intercolonial.....	274,388	244,897	D. 29,491
Total.....	4,931,366	5,027,606	I. 96,240

The total coal mined, including that used and sold at mines, in 1908 was, by counties: Cape Breton, 3,030,000; Pictou, 599,000; Cumberland, 467,000; Inverness, 354,000; total, 5,350,000 tons, an increase of 187,000 tons, or 3.6 per cent., over the previous year.

The output of the Crow's Nest Pass Coal Company, British Columbia, for the year ended Dec. 31 was, in long tons:

	1907.	1908.	Changes.
Coal.....	981,939	986,230	I. 4,291
Coke.....	231,368	269,944	I. 38,576

The December output is estimated on the actual production for two-thirds of the month.

United States Coal Exports—Exports of fuel from the United States, year ended Dec. 31, long tons:

	1907.	1908.	Changes.
Anthracite.....	2,698,072	2,752,354	I. 54,286
Bituminous.....	10,454,677	9,100,819	D. 1,353,858
Total coal.....	13,152,749	11,853,177	D. 1,299,572
Coke.....	874,689	622,228	D. 252,461

Coal furnished to steamships in foreign trade not yet ascertained. Canada took in 1908 a total of 9,252,943 tons of coal. The decrease in coal in 1908 was 9.9 per cent.; in coke, 28.9 per cent.

United States Coal Imports—Imports of fuel into the United States, year ended Dec. 31, long tons:

	1907.	1908.	Changes.
Anthracite.....	9,896	16,483	I. 6,587
Bituminous.....	2,116,122	1,487,116	D. 629,006
Total coal.....	2,126,018	1,503,599	D. 622,419
Coke.....	132,636	129,591	D. 2,946

Canada furnished 1,107,737 tons of coal and nearly all the coke in 1908; Australia, 327,441 tons of coal. Imports are mainly on the Pacific Coast. The decrease in coal in 1908 was 29.3 per cent.; in coke, 2.2 per cent.

Spanish Coal Imports—Imports of coal into Spain 11 months ended Nov. 30 were 1,760,969 metric tons, a decrease of 23,618 tons; imports of coke, 255,023 tons, an increase of 27,371 tons.

German Coal Syndicate—The Rhenish-Westphalian Coal Syndicate, which handles about 55 per cent. of the coal output of Germany, has made public its figures for 1908. The principal results are as follows, in metric tons:

Coal:	1907.	1908.	Changes.
Production.....	80,156,000	81,921,000	I. 1,765,000
Sales.....	80,147,000	79,884,000	D. 263,000
Coke sales.....	15,535,500	12,820,500	D. 2,714,700
Briquet sales.....	2,860,100	3,129,200	I. 269,100

The efforts made to increase export sales, in order to compensate for reduced house consumption met with little success.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on Jan. 22: Best Welsh steam, \$3.48; second, \$3.36; thirds, \$3.24; dry coals, \$3.60; best Monmouthshire, \$3.18; seconds, \$3.06; best small steam, \$2.04; seconds, \$1.74. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, Feb. 3—The iron and steel markets generally show little or no improvement over the last report. They are still in a waiting condition. This condition is emphasized by a very general impression in the trade that a general reduction in prices may be looked for before long.

In pig iron comparatively little new business has been done. Most of that going is in basic iron, and there is manifest some disposition on the part of furnaces to accept a lower price in order to secure orders. Thus, some considerable sales of basic are reported at \$17 for Seaboard delivery or \$16 at Pennsylvania furnaces. A considerable order for foundry, the largest of the week, is reported taken at \$16.95 for No. 2X, Seaboard delivery.

Finished material is dull, except for structural material, in which small orders have been placed, making up a considerable total tonnage. Most of these have been taken by contracting companies at rates which imply a cut in material prices.

Orders for rails are not coming. The Pennsylvania Railroad Company has placed orders for 2200 steel cars for its lines west of Pittsburgh, the order being divided among the following companies: Cambria Steel, 1000; Pressed Steel Car, 500; American Car and Foundry, 600; Standard Steel Car, 100 cars.

Pig Iron and Steel Production—As stated in detail elsewhere, the production of pig iron in the United States in 1908 was 15,936,018 long tons, a decrease of 9,845,343 tons, or 38.1 per cent., from 1907. The production of bessemer steel was 6,116,755 tons, a decrease of 5,550,754 tons, or 47.5 per cent.

Lake Superior Corporation—A reorganization of this company has been effected, which includes the investment of \$6,000,000 of British capital in the allied industries of Sault Ste. Marie. The new interests are represented by Robert Fleming, of Edinburgh and London, and Dr. F. S. Pearson, of London and New York. It is understood that the general direction of the affairs of the corporation will be intrusted to Dr. Pearson, who is prominent in connection with several Canadian industrial enterprises, being a director of the Dominion Iron and Steel and the Dominion Coal companies. The plans in contemplation include extensive additions to the blast furnaces and mills at the Sault, and the extension of the Algoma Central railway to connect with the Grand Trunk Pacific. Close investigation of the condition and possibilities of the company will be made by Dr. Pearson before the course to be pursued is finally determined. The last installment of the loan of \$2,000,000, guaranteed by the Ontario government in 1904, of which \$1,000,000 remained due, was repaid on Jan. 13, and the guarantee canceled.

Baltimore

Feb. 2—Exports from this port during the week included 1,575,600 lb. steel billets to Glasgow, Scotland.

Birmingham

Feb. 1—The aggregate business of the past month will equal the production and the greater portion of the trading was done on the basis of \$13 per ton, No. 2 foundry. There was some iron sold under \$13. Since that time there has been a strengthening in the quotations and the new month is opening up with \$13 asked on all sides. The shipments of iron have been steady while the home consumption is beginning to show improvement. The cast-iron pipe makers have purchased recently to tide them over a little period. Their trade is healthy. The machine shops and foundries are doing better. The steel plant at Ensley is working practically in all departments and the output is satisfactory. There is a good demand for all shapes of steel, and so far as can be learned there have been no concessions made in this line in this district.

Chicago

Feb. 1—Dulness continues in the iron market. Pig iron sales are confined to needs of the immediate future—30 to 90 days from the date of the sale. The needs of melters probably are increasing slightly, but they are buying more closely to current requirements than in the closing months of 1908. By some observers of the market this condition is ascribed to the uncertainty of the trade about tariff re-

vision. It seems more generally evident now, however, that the revival of business will be slow and the foundryman has learned caution. The size of lots varies from a carload up to 200 or 300 tons, on the great bulk of the business. Inquiries have fallen off in number and are not for large individual amounts.

To say that prices are holding firm is to say that for much of the business now being done \$13 Birmingham (\$17.35 Chicago) for Southern and \$17.50 Chicago for Northern No. 2 pig iron is doubtless being obtained. There can be no doubt, however, that on some business 25c. less is the price and any prospect of a transaction in which a large amount of tonnage would be concerned would bring 50c. less—perhaps even a lower price. This obtains more closely on Southern than Northern, the production of the latter being well restricted.

Iron and steel products are quiet, though there is considerable structural tonnage in sight and merchant steel is in fair demand. Coke is steady, shipments from the ovens being held down. Connellsville holds up to \$4.75 or more.

Philadelphia

Feb. 3.—The makers and agents of furnaces report a quiet and unsatisfactory market. The only exception is a little temporary activity in basic and bessemer, the aggregate of which may reach 15,000 tons with inquiries amounting to that much more. All other kinds of crude iron are neglected. The consumption of material for cast pipe is heavy and there are inquiries from pipe works but they are not likely to result in business very soon unless makers shade prices. Strong concerns in this territory are not making any effort to get business. Foundrymen are buying very little this month.

Steel Billets—Further business on a small scale is reported this week, including a few lots of forging billets. Prices hold their own.

Structural Material—Large orders for structural material are coming along, and are taken at cut prices. A general improvement is believed to be at hand in this branch.

Rails—Good sized orders for mine rails continue to come.

Scrap—Interest in scrap has again subsided, and dealers are not able to report any business of importance.

Pittsburg

Feb. 2.—There has been no improvement in the iron and steel markets and the prospects seem to be getting worse instead of better. The general situation is extremely disappointing and consumers and jobbers are only buying for immediate requirements. Mill operations, however, do not show much falling off,

although in some lines the large concerns have been compelled to curtail production. The uncertainty regarding the proposed revision of the tariff, together with persistent rumors of a probable general readjustment in prices are assigned as the reasons for the delay in placing large orders. It is known that the independent interests are cutting prices on sheets, plates and structural shapes, but the Steel Corporation concerns, the Jones & Laughlin Steel Company and the Republic Iron and Steel Company are adhering strictly to the established prices. Representatives of the large interests deny that any price reduction is contemplated, but the rumors are sufficient to cause consumers to hold off. The heavy buying of the jobbers that usually occurs at this season of the year has not materialized and the outlook is not regarded as particularly bright except in wire products and tinplate.

Pig Iron—The market is unusually irregular and former quotations are ignored by furnaces and dealers in efforts to get what little new business is offered. Some of the large producers are trying to maintain prices, but without success. An indication of the condition of the market may be found in a sale of 300 tons of No. 2 foundry made to a Pittsburg interest for delivery in the second quarter. A number of the dealers were after the business, one of them bidding \$15, Valley furnace, but did not get the contract, as it went at a lower price. Bessemer iron can be had for first quarter shipment at \$16 at furnace, and while basic is quoted at \$15.50 and malleable bessemer at \$15.75, it is believed that if any business was offered fully 50c. a ton less could be easily done. Gray forge is quoted nominally at \$14.50. These prices are all at Valley furnaces.

Steel—A sale of 2000 tons of billets last week is the only new business in crude steel. Prices on bessemer and open-hearth billets remain at \$25, Pittsburg, with freight divided. Plates are still quoted at 1.60c., but this price is being shaded. Merchant steel bars at 1.40c. are firm.

Sheets—Some new business is coming out almost every day, but it is being taken by independents at low prices. Regular quotations continue, black sheets, 2.50c. and galvanized 3.55c. for No. 28 gage.

Ferro-Manganese—Prices are weak, quotations for prompt shipment being \$45.50@46 a ton.

Foreign Iron Trade

As reported by the American Iron and Steel Association, the total production of all kinds of pig iron in Canada in 1908 amounted to 563,672 tons, against 581,146 tons in 1907, a decrease of 17,474 tons, or about 3 per cent. In the first half of 1908 the pig-iron production of Canada

amounted to 307,074 tons and in the second half to 256,598 tons, a decrease of 50,476 tons.

German Iron Production—The German Iron and Steel Union reports pig-iron production of the German furnaces in December at 1,016,526 metric tons, an increase of 85,788 tons over November. For the 12 months ended Dec. 31 the total make was, in metric tons:

	1907.	1908.	Changes:
Foundry iron....	2,259,416	2,254,644	D. 4,772
" " " " " "	780,113	635,228	D. 150,885
Steel pig.....	1,034,650	934,940	D. 99,710
Bessemer pig.....	471,355	361,472	D. 109,883
Thomas(basic)pig	8,494,226	7,627,227	D. 866,999
Total.....	13,045,760	11,813,511	D. 1,232,249

The total decrease in 1908 was 9.4 per cent. Steel pig includes spiegelisen, ferro-manganese, ferrosilicon and all similar alloys. The lightest decrease was in foundry iron.

Metal Market

New York, Feb. 3.—The metal markets continue in a rather depressed position, the January results having been generally unfavorable. Copper is governed largely by the European markets.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Dec. 1908..	\$ 7,358,707	\$ 5,522,538	Exp. \$2,235,169
" 1907..	1,004,441	44,448,515	Imp. 43,444,074
Year 1908..	71,215,456	50,246,099	Exp. 30,969,357
" 1907..	55,215,681	143,398,072	Imp. 88,182,391
Silver:			
Dec. 1908..	4,726,289	4,382,290	Exp. 343,999
" 1907..	4,413,698	4,222,036	" 191,662
Year 1908..	51,897,671	42,196,966	" 9,640,706
" 1907..	61,625,866	45,912,360	" 15,713,506

Exports from the port of New York, week ended Jan. 30: Gold, \$1,150,000, chiefly to Ipanama and Argentina; silver, \$1,070,594, chiefly to London. Imports: Gold, \$41,163; silver, \$18,183, both from the West Indies and South America.

No gold has been taken this week in New York for export to Europe. A total of \$1,750,000 has, however, been shipped to Argentina on London account.

Gold—The price of gold in the open market in London has fallen off slightly this week, bar gold being quoted at 77s. 9d. per oz., and American eagles at 76s. 4d. The Bank of France has stopped buying gold for the present, being apparently satisfied with its reserve holdings, now that the Russian loan has been financed. Nearly all the gold bought in London this week was taken by the Bank of England.

Platinum—There is no change in prices, dealers in New York quoting \$23.50@24.50 per oz. for refined platinum, \$26.50 for hard metal and \$19@21 for scrap. The market is very dull, with light sales.

Silver—The market has ruled steady the past week and closes firm at 24d. in London on buying by Chinese banks.

SILVER AND STERLING EXCHANGE						
Jan.-Feb.	28	29	30	1	2	3
New York....	51½	51½	51½	52½	51½	52½
London Ex....	23½	23½	23½	24	23½	24
Sterling Ex....	4.8740	4.8765	4.8770	4.8775	4.8770	4.8765

New York quotations, cents per ounce Troy, fine silver; London, pence per ounce sterling silver, 0.925 fine.

Shipments of silver from London to the East, year to Jan. 21, reported by Messrs. Pixley & Abell, London:

	1908.	1909.	Changes.
India.....	£ 298,000	£ 216,110	D. £ 81,890
China.....	91,000	80,000	D. 11,000
Straits.....		61,000	I. 61,000
Total.....	£ 389,000	£ 357,110	D. £ 31,890

Imports for the week, £200,000 from New York; exports, £61,000 coin to the Straits, and £110,000 bars to India; £171,000 in all.

Copper, Tin, Lead and Zinc

	Copper.			Tin.	Lead.		Spel'r.
Jan.-Feb.	Lake, Cts. per lb.	Electrolytic, Cts. per lb.	London, £ per ton.	Cts. per lb.	New York, Cts. per lb.	St. Louis, Cts. per lb.	New York, Cts. per lb.
28	13½ @14	13½ @13½	58½	27½	4.12 @17.17	3.97½	5.07 @5.10
29	13½ @14	13½ @13½	58½	27½	4.12 @17.17	3.97½	5.07 @5.10
30	14 @13½	13½ @13½	58½	27½	4.12 @17.17	3.97½	5.07 @5.10
1	13½ @13½	13½ @13½	57½	27½	4.10 @17.00	3.95	5.05 @5.07
2	13½ @13½	13½ @13½	58½	27½	4.10 @17.00	3.95	5.05 @5.07
3	13½ @13½	13½ @13½	58½	27½	4.10 @17.00	3.95	5.05 @5.07

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations for spelter are for ordinary Western brands; special brands command a premium. Spelter prices at St. Louis, Jan. 28-Feb. 3, were 0.15c. below New York.

Copper—The liquidation in the London market to which reference has previously been made continued until Feb. 1. Since then there has been a better tone and reports from abroad are to the effect that the liquidation of speculative accounts appears to be completed for the time being. However, it is well known that speculative copper is still being carried both on this side and the other. Refined copper declined here in sympathy with Standard. Between Jan. 28 and 30 some fair sales, both of Lake and electrolytic, were made to domestic consumers. Since Monday,

business has been of less amount, but at the close inquiries from abroad have been in the market. Late on Tuesday, the United Metals Selling Company announced a reduction of its price for electrolytic to 13½c., delivered, 30 days, but so far this has not resulted in bringing about an increase in buying. The close is uncertain at 13½c. for Lake copper; 13½c. for electrolytic in ingots, cakes and wirebars. The average of the week for casting copper is 13½c. cents.

Copper sheets, cold-rolled, 20c.; hot-rolled, 19c. per lb., base. Copper wire is ½c. lower, at 15½c. base, carload lots at mill.

The Standard market turned weak again last Friday, and bordered on demoralization on Monday when £57 7s. 6d. for spot and £58 7s. 6d. for three months was reached. The liquidation having ceased, covering of short sales began on Tuesday, carrying prices up to £59 2s. 6d. for spot and £60 for three months. The close is again easier at £58 17s. 6d. for spot and £59 10s. 3d. for three months.

Refined and manufactured sorts we quote: English tough, £63; best selected, £62@63; strong sheets, £74@75.

January was a gloomy month in the copper market. During the first day or two round quantities were sold, but a quieter tone followed immediately, and then discouraging reports from Europe caused prices to give way, a fair tonnage being sold at the decline. In the latter half of the month the publication of exaggerated estimates of accumulated stock on this side led to liquidation in the London market of some of the large speculative accounts that had been carried for several months. This caused a break in the market for Standard, and thereafter the decline was rapid, both at London and New York. The London parity being below New York throughout the second half of the month, European consumers bought their supplies out of London warehouse and sales in New York for export were practically nil. This is reflected in the decrease in the statistics of visible supply reported from London, and in the falling off in exports from America. The exports reported were, of course, to a large extent copper sold in December and November. One of the large agencies, in particular, was successful in disposing of its January product during the big sales of early November, but the agencies generally were much less fortunate. Demand in January was small, and recognizing this, some of the sellers held aloof, maintaining a nominal asking price of 14½c., delivered, 30 days, but receiving no orders, while others were aggressive sellers at repeated concessions, capturing the business offered, which was chiefly for domestic account. The sellers of Lake being far less eager to realize, an unusually large disparity between the prices for Lake and electrolytic developed.

Exports from New York and Philadelphia for the week are reported at 3483 long tons copper. Our special correspondent gives the exports from Baltimore at 1074 long tons.

Copper exports in January were 18,540 long tons, against 21,590 in December.

Tin—In sympathy with copper, the tin market in London declined, reaching its lowest point on Feb. 1 at £123 15s. for spot and £125 10s. for futures. Some demand which was brought about by the lower values in this market and inquiries which, in consequence, were cabled abroad, tended to stiffen values in London. The advance, however, was not maintained and the market closes flat at £126 2s. 6d. for spot and £128 for three months.

In New York, tin can be bought at the close at about 27½c. cents.

Visible stocks of tin Feb. 21, reported in long tons:

	In Store.	Afloat.	Total.
London.....	8,994	4,128	13,112
Holland.....	1,833	187	2,010
U. S., exc. Pacific ports...	3,559	3,204	6,763
Total.....	14,376	7,519	21,895

The total shows an increase of 1967 tons over the January report.

Exports of tin from the Straits, 11 months ended Nov. 30, long tons: United States, 9432; Great Britain, 38,206; other Europe, 7900; India and China, 2000; total, 57,538 tons, an increase of 2933 tons over the previous year.

Arrivals of tin at Pacific Coast ports, year ended Dec. 31, were 1943 long tons in 1907, and 1756 in 1908; a decrease of 187 tons.

Tin output of the Federated Malay States for the 12 months ended Dec. 31 is reported at 38,431 long tons in 1907, and 50,646 in 1908, an increase of 2215 tons.

Lead—The market is extremely dull and there is more lead pressed for sale than can be placed, so that prices have declined further and the market closes weak at 4.10@4.15c. New York, and 3.95@4c. St. Louis.

The London market is also somewhat lower and quotations are cabled at £13 for Spanish lead, £13 2s. 6d. for English lead.

Spelter—The metal, which has been held back in anticipation of a higher market, in view of the exorbitant prices which have ruled for ore, is now being forced for sale, due to a decline which has taken place in Joplin ore prices. Consumers show little interest, as the galvanizing business is less active. The close is weak at 4.90@4.92½c. St. Louis, 5.05@5.07½c. New York.

The London market is quoted at £21 for good ordinaries and £21 15s. for specials.

Base price of sheet zinc is 7c. f.o.b. La Salle-Pern, Ill. less 8 per cent,

Other Metals

Antimony—The market is still quiet, with only moderate current sales. There is no material change in prices, 8¼@8½c. being named for Hallett's; 8@8½c. for Cookson's; 7½@7¾c. for ordinary brands.

Aluminum—The Aluminum Company of America continues to quote 24c. base for No. 1 ingots; 33@34c. base for sheets. Foreign metal is offered at 22c. for ingots, but can probably be had a shade lower for good orders.

Quicksilver—New York quotations are unchanged at \$45@46 per flask of 75 lb. San Francisco prices are \$45@46 for domestic orders, and \$43@44 for export. The London quotation is £8 7s. 6d. per flask, with £8 6s. 3d. named by jobbers. Business is quiet.

Nickel—Large lots, contract business, 40@45c. per lb. Retail, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. These quotations are for spot nickel. The price for electrolytic is 5c. higher.

Cadmium—In 100-lb. lots, 75c. per lb., at Cleveland, Ohio.

Magnesium—This metal is offered in New York at \$1.25 per lb. in 100-lb. lots. The price is \$1.40 per lb. for 5-lb. lots.

Imports and Exports of Metals

Exports and imports of metals in the United States for the year ended Dec. 31 are reported as follows, in the measures usual in the trade:

Metals.	Exports.	Imports.	Excess.
Copper, long tons.....	301,080	97,636	Exp. 203,444
Copper, 1907.....	234,619	113,181	Exp. 121,438
Tin, long tons.....	244	36,832	Imp. 36,588
Tin, 1907.....	562	36,832	Imp. 36,270
Lead, short tons.....	76,354	113,046	Imp. 36,692
Lead, 1907.....	61,592	79,815	Imp. 28,313
Spelter, sh. tons.....	2,640	881	Exp. 1,759
Spelter, 1907.....	563	1,778	Imp. 1,215
Nickel, lb., 1907.....	9,770,248	16,596,423	Imp. 6,816,155
Nickel, 1907.....	8,772,578	18,418,306	Imp. 9,645,727
Antimony, lb., 1907.....	8,114,651	Imp.	8,114,651
Antimony, 1907.....	8,662,683	Imp.	8,662,683
Platinum, oz., 1907.....	49,808	Imp.	49,808
Platinum, 1907.....	74,208	Imp.	74,208
Quicksilver, lb., 1907.....	224,692	Exp.	224,692
Quicksilver, 1907.....	384,913	Exp.	384,913
Aluminum, value.....	\$330,092	Exp.	\$330,092
Aluminum, 1907.....	304,938	Exp.	304,938

Ores, etc.:		
Zinc oxide, lb., 24,016,054.....	Exp. 24,016,054	
Zinc oxide, '07, 26,512,920.....	Exp. 26,512,920	
Zinc dross, lb., 16,810,259.....	Exp. 16,810,259	
Zinc dross, '07, 19,180,737.....	Exp. 19,180,737	
Zinc ores, long tons.....	49,996	Imp. 25,685
Zinc ores, 1907.....	18,171	
Antimony ores, lb., 3,290,922.....	Imp. 3,290,922	
Ant. ores, 1907.....	2,780,186	Imp. 2,780,186

Copper, lead and nickel include the metal contents of ores, matte, bullion, etc. The exports given include reexports of foreign material. Imports of zinc ores in 1908 were 21,012 tons calamine and 26,084 tons other ores; in 1907 only partially reported.

Spanish Metal Exports

Exports of metals and ores from Spain, 11 months ended Nov. 30, metric tons, as reported by *Revista Minera*:

Metals:	1907.	1908.	Changes.
Copper.....	8,258	13,109	I. 4,851
Copper precipitate.....	16,845	18,020	I. 2,175
Zinc.....	1,321	1,386	I. 65
Lead.....	104,435	171,940	I. 7,505
Quicksilver.....	1,500	1,504	I. 4
Minerals:			
Iron ore.....	8,108,251	6,780,398	D. 1,327,853
Copper ore.....	1,115,232	1,006,908	D. 108,324
Zinc ore.....	143,844	118,736	D. 25,108
Lead ore.....	5,110	2,226	D. 2,884
Manganese ore.....	62,568	20,857	D. 41,711
Pyrites.....	1,216,929	1,299,312	I. 82,383

Exports of salt, 452,758 tons in 1907, and 518,101 in 1908; increase, 65,433 tons.

Zinc and Lead Ore Markets

Joplin, Mo., Jan. 30—The highest price paid for zinc sulphide ore on this week's market was \$43 per ton, the base ranging from \$37 to \$40 per ton of 60-per cent. zinc. Zinc silicate sold on a base of \$19 to \$21 for 40 per cent. zinc, and as high as \$26 per ton. Average, all grades \$36.58. Lead was largely sold this week on a base price also, offerings of \$54 per ton of 80-per cent. lead being made, running the high price to \$56. Average, all grades, \$52.92 per ton.

Four days of the week were ideal for outputting, but a severe storm formed Thursday, the temperature changing to be-

NOTE.—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all zinc ore sold. Lead ore prices are the average for all ores sold.

low zero. A tornado swept the district for 24 hours, the gale reaching, at times, as high as 50 miles per hour. Many tail elevators and smokestacks were leveled, and in some instances the falling elevators crushed in a portion of the mills. It is estimated the output was decreased this week approximately 8 per cent., and it may decrease next week's output 12 to 15 per cent.

Chemicals

New York, Feb. 3—The market as a whole has shown no signs of activity. Dealers are buying only according to their immediate needs.

Copper Sulphate—Demand is fair and trade conditions remain unchanged. Quotations are steady at \$47.5 per 100 lb. for carload lots and up to \$5@5.50 per 100 lb. for smaller parcels.

Arsenic—The market is dull, only a few small sales being reported. Quotations are 3@3½c. per lb. for white arsenic.

Nitrate of Soda—A good normal trade on this article has been done during the past week. Current quotations are 2.17½c. for spot and 2.15c. for futures, which are a shade higher than last week.

Imports and Exports—The imports and exports of chemicals and raw materials in the United States 12 months ended Dec. 31 were as follows:

	Imports.	Exports.	Excess.
Copper sulph. lb., 1907.....	7,663,882	E. 7,663,882	
Bleach, lb., 1907.....	74,023,059	121,611	I. 74,480,548
Potash salts, lb., 1907.....	300,073,012	3,046,689	I. 299,026,323
Soda salts, lb., 1907.....	11,366,614	838,852	I. 10,527,762
Acetate lime, lb., 1907.....	66,703,015	E. 66,703,015	
Nit. of soda, tons.....	310,713	9,965	I. 300,758
Phosphates, tons.....	26,734	1,228,860	E. 1,202,126
Pyrites, tons.....	19,118	27,894	E. 8,776
Pyrites, tons.....	668,115	I. 668,115	

Estimating sulphur contents of pyrites, the total sulphur imported was approximately 286,364 long tons.

Mining Stocks

New York, Feb. 3—The general stock markets have been somewhat irregular during the week, but on the whole rather dull. The volume of trading was not heavy at any time. A period of weakness was followed by some recovery, so that there was no marked change in quotations. The report that the Supreme Court decision on the commodity clause of the Interstate Commerce law would be given out had some effect on the anthracite coal stocks; but the postponement of the decision affected them but slightly.

On the Curb the copper stocks developed some weakness, but recovered at the close. They were not especially active, the whole market being inclined to quiet. Cobalt stocks were sluggish, with no material change in prices. The Nevada gold stocks were inclined to be dull, and business in them was not heavy.

Boston, Feb. 2—It would seem as if copper mining shares had been sold almost to a standstill. After a sharp break, which extended pretty much through the entire list, prices recovered as sharply, although net declines are to be recorded for the week as a rule. The decision by the Cincinnati Court of Appeals in favor of the Calumet & Hecla proved a fillip and prices responded readily under the leadership of Osceola and Calumet & Hecla. Concentrated buying in Isle Royale caused an advance from \$24 to \$26.75 even while the balance of the market was weak. Conferences between the Calumet & Hecla and Osceola people were continued and again discontinued without accomplishing anything. Report says that Mr. Bigelow demands \$8,000,000 to capitulate.

Alonez had a \$6 spurt Monday to \$40. and closes the week with a net advance of \$6.75. The striking of the Kearsarge lode with rich formation was responsible for this. Calumet & Arizona had a bad break from \$110 to \$97, but rallied to \$103.75 tonight. Amalgamated fell \$5.75 to \$72.75, rallying to \$75.37, and Copper Range broke \$5.75 to \$7.25, recovering to \$74.25. North Butte broke \$7.75 to \$70.50, rallying to \$75.50. Osceola fell \$7 to \$12.3, rallying to \$13.3 on the Cincinnati decision, and Calumet & Hecla, after falling \$25, to \$62.5, rose to \$640.

Superior Copper rose from \$35.75 to \$38.50. Utah Consolidated fell \$3.75 to \$30.75, rallying to \$41.

Curb prices have been more regular and closed strong tonight.

THE MINING INDEX

The editors of this paper read all the important publications of the world that relate to mining and the treatment of minerals. This index is published as a reference for all interested and to make it impossible for readers of the *ENGINEERING AND MINING JOURNAL* to miss any important article published anywhere.

We will undertake to furnish a copy of any article (if in print) in the original language, for the price quoted. Where no price is quoted the cost is unknown. These papers are not kept in stock, but must be ordered from the publisher; hence there will be some delay for foreign papers.

No accounts can be opened for these small amounts, but remittance must be sent with order. For the convenience of those making small but frequent remittances, coupons are furnished at the following prices: 20 cents each, six for \$1.00, thirty-three for \$5.00 and one hundred for \$15.00. This arrangement will be especially appreciated by foreign readers and men in distant mining camps. Where remittances are made in even dollars we will return the excess over an order in coupons upon request.

ALUMINUM

8369—BRITISH WORKS—Three New British Aluminum Works. (Electrochem. and Met. Ind., Jan., 1909; 28 pp.) Describes the plants at Dolgarrog, Walsend and Kinlochleven quite fully and gives many details of their operations. Special mention of the aluminum furnaces is made. The first two works belong to the Aluminum Corporation, Ltd., and the latter are being erected by the British Aluminum Co. 40c.

8370—CASTINGS—Production of Aluminum Castings. (Foundry, Dec., 1908; 6 pp.) Describes the manipulation of aluminum in the foundry and the practice of the Allyn Brass Foundry Co., probably the largest consumer of aluminum in the world. 20c.

8371—ELECTROLYTIC REDUCTION of Aluminum as a Laboratory Experiment. M. de Kay Thompson. (Electrochem. and Met. Ind., Jan., 1909; 2 pp.) Contains tabulated results of a series of laboratory experiments, and describes the difficulties encountered in attempting to electrolyze a solution of aluminum oxide in melted cryolite, according to the Hall patent. 40c.

AMMONIUM SULPHATE.

8372—PRODUCTION of Ammonium Sulphate. C. G. Atwater. (Am. Fertilizer, Dec., 1908; 5 pp.) A discussion of the production of ammonium sulphate as a by-product from coke ovens, giving tables of the world's output as well as consumption. 20c.

BARYTES.

8373—TENNESSEE—Barytes in Tennessee. A. H. Fay. (Eng. and Min. Journ., Jan., 1909; 3 p.) A short review of the barytes industry in Tennessee during 1908. 20c.

BORAX.

8374—BORAX. (Eng. and Min. Journ., Jan. 9, 1909; 3 p.) A short review of the borax industry in California and the operations of the Pacific Coast Borax Company. 20c.

CALCIUM CYANAMIDE

8375—CALCIUM CYANAMIDE—On the Utilization of the Atmospheric Nitrogen in the Production of Calcium Cyanamide, and Its Use in Agriculture and Chemistry. Albert R. Frank. (Trans. Faraday Soc., Oct., 1908; 30 pp.) A historical résumé of the various attempts to produce calcium cyanide, together with tables showing its value as a fertilizer compared with other fertilizers now in use. Illustrated. 20c.

CEMENT

8376—CEMENT WORKS at Souham. (Engineer, Jan. 1 and 8, 1909; 4 pp.) A description of the cement works of Kaye & Co., Ltd., with plan and sectional drawings of the entire plant, including the two rotary kilns used. 60c.

8377—PORTLAND CEMENT INDUSTRY—A New Viewpoint of the American Portland Cement Industry. E. C. Eckel. (Eng. Rec., Jan. 9, 1909; 4 p.) Paper read before the annual meeting of the Assn. of Am. Portland Cement Mfrs., in which the author discusses the

future growth of the cement industry; possible price regulation; influence of patents; improvements in marketing conditions and the development of export trade. Illustrated. 20c.

COAL AND COKE

8378—ALBERTA—Coalfields of Alberta. Geo. B. Ellison. (Northwest Min. News, Jan., 1909; 2 pp.) The author gives a short discussion of the developments that are taking place in the Northwest. He considers that the coalfields of Alberta are very extensive. Illustrated. 20c.

8379—ANALYSIS—Some Fundamental Considerations on Coal. W. Jones. (Electrochem. and Met. Ind., Jan., 1909; 1 p.) This paper has special reference to the economic value of coal from the buyer's standpoint based upon the chemical analysis.

8380—AUSTRALIA—Coalfields and Collieries of Australia. F. D. Power. (Aust. Min. Stand., Nov. 4 and 18, 1908; 2 pp.) Continuation of article previously indexed. 60c.

8381—BRIQUETTED COAL—Comparative Tests of Run-of-Mine and Briquetted Coal on Locomotives. W. F. M. Goss. (Bull. No. 363, U. S. Geol. Surv., 1908; 57 pp.) A discussion of the briquet industry in Europe, with tabulated results and comparative tests, together with chemical analyses. Also notes on foreign specifications for briquets. A short bibliography is attached. Illustrated. 40c.

8382—CANADA—The Mining Operations of the Dominion Coal Company. III and IV. F. W. Gray. (Can. Min. Journ., Dec. 15, 1908, and Jan. 1, 1909; 9 pp.) This article gives a short historical sketch of the early operations and a description of the present plant. Illustrated. 40c.

8383—CHARCOAL KILNS OF VARIOUS CONSTRUCTIONS—Hilding Bergström. (Jernkontors Annaler, 1908; 42 pp.) Describes the various types of charcoal kilns employed in Sweden and discusses the output of charcoal and by-products and the economic results from their operation.

8384—CHINA—Coal Mining in China. T. Read. (Min. and Sel. Press, Jan. 2, 1909; 24 pp.) Deals principally with the geographical distribution of the principal coal fields in China and gives a table of analyses of the various coals. Illustrated. 20c.

8385—COAL DUST—Appliances for Dealing with Coal Dust at the Pitt Mouth. (Iron and Coal Tr. Rev., Jan. 8, 1909; 2 pp.) Translation of an article in "Glückauf." Gives drawings and descriptions of a number of coal dust extractors that are used at the various collieries of the Ruhr district. Illustrated. 40c.

8386—COAL DUST—Is Coal Dust, as Such, Explosive? Audley H. Stow. (Eng. and Min. Journ., Jan. 2, 1909; 3 pp.) Study of the chemical reactions that occur in dust explosions and a percentage estimate of fatalities due to falls of roof and side. 20c.

8387—COAL DUST—Spraying Coal Dust as a Colliery Safeguard. D. Harrington. (Eng. and Min. Journ., Jan. 23, 1909; 3 pp.) A description of an efficient sprinkling system, with detailed costs of installation and operation as carried on in the mines of Utah. Illustrated. 20c.

8388—COKE—Some Notes on Coking Plants. W. S. McCarty. (Students' Magazine, Ballarat School of Mines, Vol. XI, No. 4, 1908; 3 pp.) The author discusses coal washing preparatory to coking manufacture, and points out that there is much room for improvement for the methods now in use in N. S. W., as none of the coking plants utilize the by-products. Illustrated. 40c.

8389—COMPOSITION OF COAL—Chemical and Physical Examination of Coals. (Aust. Min. and Eng. Rev., Dec. 5, 1908; 3 pp.) This article discusses the general methods used in determining hygroscopic, volatile carbons, fixed carbon, ash, sulphur, and the composition of the ash. 40c.

8390—DISCIPLINE IN MINES. S. Reynolds. (Eng. and Min. Journ., Jan. 23, 1909; 2 p.) In this article the author emphasizes the fact that laws must be enforced and that punishment for violation should be severe. 20c.

8391—ELECTRIC POWER—The Distribution of Electric Power in Mines. (Iron and Coal Tr. Rev., Dec. 4, 1908; 12 pp.) Gives an essentially a description of a distribution board for the handling of high tension electric currents in the coal mines of Reyrolle & Co., Eng. Illustrated. 40c.

8392—ELECTRICITY—The Installation of Electricity in Coal Mines. W. A. Thomas. (Min. Wid., Dec. 26, 1908; 1½ pp.) A discussion of a set of rules governing electrical installation, particularly as to the use of a gauzeless lamp. Illustrated. 20c.

8393—EXPLOSION at Benwell Colliery. R. A. S. Redmayne. (Min. Eng., Jan., 1909; 2 pp.) A description of the physical condition of the mine prior to the explosion and the tracing of the accident to the use of a gauzeless lamp. Illustrated. 20c.

8394—EXPLOSIONS—Views Respecting Coal Mine Explosions. (Eng. and Min. Journ., Jan. 2, 1909; 4½ pp.) A symposium of opinions by Messrs Scholz, Virgin, Nelms, Butler and others. 20c.

8395—GREAT BRITAIN—The Coal and Coke Trades of the United Kingdom in 1908. (Iron and Coal Tr. Rev., Jan. 1, 1909; 6½ pp.) A general review of the commercial conditions, together with statistics of the output of the various districts, and diagrams showing the fluctuation in prices for the years 1907 and 1908. 40c.

8396—HOISTING—Electrical Winding in South Wales. (Elec. Rev., Jan., 1909; 4½ pp.) A description of the first electrically driven hoist installed by the Great Western Colliery in South Wales. Illustrated. 20c.

8397—ILLINOIS—The O'Gara Coal Company's Mines in Illinois. R. S. Moss. (Min. Eng., Dec. 19, 1908; 1½ pp.) A description of the operations in the greatest coal producing section of the State. Extensive electric equipment recently installed. A comparison of the coal with the Hocking valley (Ohio) coals. Illustrated. 20c.

8398—MIDDLE WEST—Mining Industry of the Middle West. (Min. and Sel. Press, Jan. 2, 1909; 1½ pp.) This article deals principally with the coal mining industry in Illinois and vicinity. 20c.

8399—MINING METHODS for Maximum Recovery of Coal. H. V. Hesse. (Black Diamond, Jan. 16, 1909; 3 pp.)

The author discusses incompetent engineering and management; unfavorable labor conditions, and the importance of owners being able to obtain quick returns on their investment. Illustrated. 20c.

8400—MINING THIN SEAMS—Notes on Conveyor Working in a Thin Seam at Garesfield Colliery. P. E. Smallwood. (Iron and Coal Tr. Rev., Jan. 8, 1909; 1 p.) A description, together with drawings, of Blackett conveyors that are used in working a 22-inch seam of coal with a panel of blue clay-stone immediately above it. This system has been used and has proved a profitable investment. Illustrated. 40c.

8401—NOVA SCOTIA—A Résumé of the Nova Scotia Coal Mining Industry for 1908. F. W. Gray. (Can. Min. Journ., Jan. 15, 1909; 3½ pp.) A description of the coal industry together with statistics showing the output of the principal companies for 1908. Also discusses the value of Nova Scotia coals as compared with those produced in the United States. 20c.

8402—NOVA SCOTIA—Explorations in Nova Scotia in 1907. Hugh Fletcher. (Can. Min. Geol. Surv. of Canada, 1908; 15 pp.) A brief review of the explorations carried on in the coal districts of Nova Scotia during 1907.

8403—PUMPS—The Arrangement of Pumps for Modern Collieries—L. J. S. Barnes. (Iron and Coal Tr. Rev., Dec. 1, 1908; 2½ pp.) In this article the Hawthorne-Davey pumps are described together with the general arrangement of a modern and up-to-date economical plant recently installed for handling 800 gal. of water per minute. Illustrated; to be continued. 40c.

8404—ROOF SUPPORT—Notes on Roof Support, Other Than Timber, Practiced in the Pas de Calais Coal Field, North of France. J. E. Phelps. (Sci. and Art Mag., Jan. 1908; 1½ pp.) A short discussion of the use of reinforced concrete in coal mining; also a brief note on the use of steel bridges. Illustrated. 20c.

8405—RUSSIAN COAL AND IRON INDUSTRY. (Iron and Coal Tr. Rev., Dec. 1908; 1 p.) This article gives statistics and prices of the coal and iron industry in Russia for the year 1908. A brief résumé of the trade conditions. 40c.

8406—SAFETY LAMPS—German Tests with Incandescent Safety Lamps. (Col. Guardian, Dec. 24, 1908; ½ p.) The author discusses the comparative safety of the phosphorus-cap, friction cap, electric methyl alcohol and cerium-iron alloy lamps. 40c.

8407—SCREENING PLANT—The Coal-Screening and Conveying Plant at the Collieries of Messrs. Burnyeat, Brown and Company, Nine Mile Point, near Newport, Monmouth. (Col. Guard., Jan. 1909; 1 p.) This article gives a detailed description, with drawings, of a screening plant having a capacity of 3000 tons per day. Illustrated. 40c.

8408—SOUTHERN STATES—The Coal Resources of the Southern States. E. W. Parker. (Mfrs. Rec., Jan. 7, 1909; 1 p.) A review of the early statistics of coal production in the Southern states with a short discussion of the coal reserves for the future. 20c.

8409—TESTS OF COAL AND BRIQUETS. (Col. Guardian, Jan. 1, 1909; 4 pp.) A discussion of the methods used and tabulation of results obtained on a series of tests of coal and briquets as fuel for housekeeping stoves. Illustrated. 40c.

8410—UNITED STATES—Coal Mining in the United States in 1908. (Eng. and Min. Journ., Jan. 9, 1909; 9 pp.) Reviews of mining conditions in many important centers of anthracite and bituminous production, with forecast of future production. Statistics of the coal and coke output. 20c.

8411—UNITED STATES—The Coal-fields of the United States. (Eng. and Min. Journ., Jan. 16, 1909; 4 pp.) A detailed map, showing the coal fields of the United States, accompanied by a description of the character of the coal, its geologic age, estimated tonnage in various fields. Illustrated. 20c.

8412—VENTILATION—The Principles of Ventilation of Mines. W. H. Hepplewhite. (Col. Guardian, Dec. 13, 1908; 1 p.) A discussion of the advantages to be obtained by splitting the air currents. 40c.

COPPER

8413—ARIZONA—The Turquoise Mining District, Arizona. J. M. Platt. (Eng. and Min. Journ., Jan. 23, 1909; ¾ p.) A short description of the geology of the district, together with some notes on the operations of a number of the more important companies. 20c.

8414—BOSTON CONSOLIDATED MILL at Gardet, Utah. Leroy A. Palmer. (Min. Wild., Jan. 2, 1909; 3½ pp.) A short description of the ore deposits, transportation system and a flow sheet of the Boston Consolidated mill. A very complete description of the mill is given. Illustrated. 20c.

8415—CANADIAN COPPER COMPANY. D. F. Brown. (Can. Min. Journ., Jan. 15, 1909; 4 pp.) Gives a very complete description of the company's plant, and especially of the converter building and the furnaces. Illustrated. 20c.

8416—COLORADO—Some Copper Deposits in the Christo Range, Colorado. Rufus M. Baggs, Jr. (Econ. Geol., Dec., 1908; 11 pp.) Gives a description of this range together with its geology, age and ore deposits. Illustrated. 60c.

8417—COPPER OUTLOOK. M. E. Applebaum. (Min. and Sci. Press, Jan. 9, 1909; 1 p.) The author gives a brief résumé of the copper industry during 1908 and looks forward to a revival of business by the middle of 1909. 20c.

8418—COPPER SITUATION. The James Douglas. (Min. and Sci. Press, Jan. 2, 1909; 4 pp.) A review of the copper industry for 1908. 20c.

8419—COSTS—Calumet & Hecla Costs—II. L. S. Austin. (Min. and Sci. Press, Dec. 26, 1908; 1½ pp.) A study of the cost of the Buffalo smelter of the Calumet & Hecla mine. 20c.

8420—DESULPHURIZING. The Pot Roasting of Copper Ores. S. Radcliff. (Aust. Min. Stand., Dec. 2, 1908; 1½ pp.) The author gives a description of a plant for desulphurizing copper ores at Wallaroo Smelting Works in South Australia. Illustrated. 40c.

8421—ELECTRIC EQUIPMENT—Mansfeld. (Germany) Electrically Operated Copper Mines—L. Frank C. Perkins. (Min. Wild., Dec. 26, 1908; 2½ pp.) This article deals principally with the utilization of furnace gases for generating electrical power to be used for pumping, hoisting, tramway, hoovers and other purposes. Illustrated. 20c.

8422—KOREA—The Kosan Mine, Korea. A. D. Weigall. (Min. and Sci. Press, Dec. 26, 1908; 1½ pp.) A history of the mine, together with a description of the copper deposits and table of ore analyses. Also a short note on the Tien Shan copper mine in Kirin province. 20c.

8423—LONDON COPPER MARKET in 1908. (Eng. and Min. Journ., Jan. 16, 1909; 2½ pp.) A résumé of market conditions of each month during the year 1908. 20c.

8424—NEVADA—Copper Mining at Ely, Nevada. C. DeKalb. (Min. and Sci. Press, Jan. 2, 1909; 3 pp.) A description of a copper mining plant in which the steam shovel is a very important factor. Illustrated. 20c.

8425—NEVADA'S GREAT COPPER CAMP. (Am. Min. Rev., Jan. 2, 1909; 1½ pp.) A short description of the Ely copper camp together with some notes on the McGill concentrator of the Cumberland-Ely mine. The Groux Concentrator at the Boston Ely and the Copper Mines Company. Illustrated. 20c.

8426—NEW MEXICO—Mining and Milling Near Silver City, New Mexico. Robert B. Brinsmade. (Min. Wild., Dec. 26, 1908; 3½ pp.) A history of the development of mining in the Apache country, together with its geological features and transportation facilities. Also a description of the Santa Rita copper deposits and the equipment of the plant. Illustrated. 20c.

8427—PENNSYLVANIA—The Newark Copper Deposits of Southeastern Pennsylvania. Edgar T. Wherry. (Econ. Geol., Dec., 1908; 14 pp.) A historical sketch of the early operations together with the geology of the region. Gives a description of the ores associated with igneous rocks. Illustrated by map. 60c.

8428—PRODUCTION of Copper in 1907. L. C. Graton. (Advance Chapter from Mineral Resources of U. S., Calendar Year 1907; 78 pp.) A brief statement regarding the conditions of the copper industry; production by States; a description of the physical conditions existing in a few of the prominent districts. Tables of imports and exports, also uses of copper and the prices. 20c.

8429—PRODUCTION—The Copper Production of North America. (Eng. and Min. Journ., Jan. 9, 1909; 7 pp.) A review of the commercial conditions for the year 1908, together with statistics of the output of copper in the principal mining districts. Illustrated. 20c.

8430—QUEENSLAND—Cloncurry Copper Mining District, Part I. L. C. Ball. (Queensland Geol. Surv. Pub. No. 215, 1908; 42 pp.) This report deals entirely with the geography, history, economics, geology and the copper ore deposits as occurring in this district. 20c.

8431—QUEENSLAND—Cloncurry Copper Mining District, Part II. L. C. Ball. (Queensland Geol. Surv. Pub. No. 215, 1908; 379 pp.) This part of the report is limited to individual descriptions of the mines. It gives the names of the operating companies together with detailed description of their operations. Illustrated. 20c.

8432—SLAG CAR Used at the Cananea Smelting Works. C. F. Shelby. (Eng. and Min. Journ., Jan. 23, 1909; 2 pp.) A description of a cast-steel bowl which has a capacity of 45 cu. ft. and is used for handling the slag from the Cananea Company's smelters. 20c.

8433—SMELTER CHIMNEY—New 500-ft. Chimney at Great Falls Smelter, Edwin Higgins. (Eng. and Min. Journ., Jan. 16, 1909; 3½ pp.) The largest chimney both in size and capacity in the world. Flue dust caught by network of wire suspended in dust chamber. Illustrated. 20c.

8434—SMELTER FUMES—Copper Fumes Converted into a Fertilizer Ingredient. J. S. Grasty. (Mfrs. Rec., Jan. 7, 1909; 1 p.) A brief description of the sulphuric acid plant recently constructed by the Tennessee Copper Company. 20c.

8435—SMELTING CONDITIONS at Salt Lake. C. De Kalb. (Min. and Sci. Press, Jan. 2, 1909; 3½ pp.) A review of the smelting industry and the economic conditions prevailing at Salt Lake. Illustrated. 20c.

8436—TENNESSEE COPPER COMPANY—Mines and Works of the Tennessee Copper Co. B. B. Gottsberger. (Min. Wild., Dec. 19, 1908; 8½ pp.) A historical résumé of the Ducktown district and a description of its smelter, power plant and the sulphuric acid plant for utilizing the blast furnace gases. Illustrated. 20c.

GOLD AND SILVER.

8437—AFRICA—West Africa, the Gold Coast Colony and Ashanti in 1908. W. F. Wilkinson. (Eng. and Min. Journ., Jan. 23, 1909; 1 p.) A review of the operations of the Ashanti Goldfields Corporation and other companies during the year 1908, together with statistics showing the tonnage and value of the output treated by the various companies. 20c.

8438—ALLUVIAL GOLD—Sources of Alluvial Gold. Walter F. Smith. (Aust. Min. Stand., Nov. 18, 1908; 2 p.) A short discussion of the origin of alluvial gold in the vicinity of Kirin, Victoria and Lisle, Tasmania. 40c.

8439—ALLUVIAL MINING—Two Problems in Alluvial Mining. Richard Hain. (Students Magazine, Ballarat School of Mines. Vol. XI, No. 4, 1908; 3 pp.) Discusses the drainage problem in alluvial deposits, and also mining costs. 40c.

8440—CALIFORNIA—Mining on the Mother Lode. E. W. Turner. (Min. and Sci. Press, Jan. 2, 1909; 1½ pp.) A short discussion of the geology and the ore deposits together with the value of the ore produced from a number of the principal mines. Illustrated. 20c.

8441—CENTRAL AMERICA—The Gold Regions of the Straits of Magellan and Tierra del Fuego. R. A. F. Penrose, Jr. (Journ. of Geology, Nov. 5, Dec. 1908; 15 pp.) A discussion of the geology and topography of the region, the discovery and distribution of the gold deposits; their occurrence and methods of prospecting. Illustrated. 60c.

- 8442—COLOMBIA—The Real Eldorado. P. L. Garrison. (Min. and Sci. Press, Jan. 2, 1909; 1½ pp.) A short history of the early Spanish explorers in the vicinity of Bogotá, Colombia. 20c.
- 8443—COLORADO—Cripple Creek in 1908. W. H. Travel. (Min. and Sci. Press, Jan. 2, 1909; 2½ pp.) A short description of the Portland, Stratton's Independence, Golden Cycle, Elkton, Vindicator and Mary McKinney mines. 20c.
- 8444—CYANELLATION—Notes on Cupelling Gold-Lead Bullion. G. Melville. (Journ. Chem. Met. and Min. Soc. of South Africa, Nov., 1908; 2 pp.) The author gives a description of the method of cupelling gold-lead bullion as it comes from the pan furnace. 60c.
- 8445—CYANIDATION—A Simple and Effective Contrivance for Filtering Gold Slime. E. Jensen. (Monthly Journ. W. A. Chamber of Mines, Nov. 30, 1908; 2 pp.) The author discusses the value of the vacuum filter process as a substitute for a filter press. Illustrated. 80c.
- 8446—CYANIDATION—Notes on Cyanidation. Leo D. Bishop. (Proc. Colo. Sci. Soc., Dec. 1908; 3 pp.) Discusses the effect of excess of lime and temperature upon the settlement of slime and gives results of some experiments on this subject. It also discusses the effect of using partially oxidized Jackline and of unsuitable lime in cyanidation. C. W. Comstock in discussing Mr. Bishop's paper shows an apparent relation between the results of Mr. Bishop's experiment on settlement and Pöissenville experiments on viscosity. 60c.
- 8447—CYANIDATION—Progress in Cyanidation. Alfred James. (Min. and Sci. Press, Jan. 2, 1909; 6½ pp.) The author discusses the slime processes also the vacuum filtration and gives some notes on ore crushing. Illustrated. 20c.
- 8448—CYANIDATION—The Adair-Usher Process. Alfred Adair. (Journ. Chem. Met. and Min. Soc. of South Africa, Nov., 1908; 4 pp.) Reply to a discussion of the above paper describing this process which was read at the May meeting, 1908. 60c.
- 8449—CYANIDATION—The Virginia & Mexico Cyanide Plant. Mark R. Lamb. (Eng. and Min. Journ., Jan. 16, 1909; 1 p.) A short description of this plant and method of operation. Illustrated. 20c.
- 8450—CYANIDATION—Zinc Dust Precipitation at Cerro Prieto. R. Linton. (Journ. Chem. Met. and Min. Soc. of South Africa, Nov., 1908; 1 p.) A discussion of the above paper on this subject which was read at the September meeting, 1908. 60c.
- 8451—ELECTRO-CYANIDE PROCESS—Operations of the Parks Electro-Cyanide Process. R. Parks. (Min. and Sci. Press, Jan. 2, 1909; 1 p.) The description of a process depending upon the solubility of the precious metals in cyanide solutions followed by electrolytic deposition. Illustrated. 20c.
- 8452—EXTRACTION—Improved Process for Extracting Metals in Ores. W. E. Greenawalt. (Min. Wld., Dec. 5, 1908; 1½ pp.) A chlorination process to be used on refractory ores depending upon the solubility of chlorine in water under various pressures. 20c.
- 8453—FINE GRINDING—Laboratory Screens: Their Use in Testing the Efficiency of Grinding Machines. E. T. Henderson. (Aust. Min. and Eng. Rev., Nov. 5, 1908; 2½ pp.) A discussion of the ratio of the mesh together with a proposed scheme for new ratio. 40c.
- 8454—FINE GRINDING—The Computation of Crushing Efficiency of Fine Grinding Machines. H. Stadler. (Journ. South African Assn. of Eng., Dec. 1908; 10 pp.) This article records a series of tests of tube mill grinding as compared with the fines obtained from the stamp mill. He gives a mathematical discussion of the question of efficiency. 80c.
- 8455—GOLD DREDGING PRACTICE in Placers of the Klamath River. C. A. Laker. Jr. (Min. Sci. Journ., Jan. 1909; 4 pp.) An outlined description of the arrangement and operation of gold dredges as practiced in Colorado's most extensively developed placer fields. Illustrated. 20c.
- 8456—GOLD DREDGING—Bucket Dredging and Pump Sluicing. H. Herzman. (Aust. Min. Stand., Nov. 18, 1908; 1 p.) The applicability and costs of bucket dredging as compared with pump sluicing. 40c.
- 8457—GOLD DREDGING—Developments in Gold Dredging in 1908. J. P. Hutchins. (Eng. and Min. Journ., Jan. 23, 1909; 3 pp.) A prosperous year in this industry as shown by great activity in California and important progress in the Klondike. 20c.
- 8458—GOLD DREDGING OPERATIONS in the California Fields. G. S. Cowdery and E. A. Sperry. (Min. Sci. Journ., Jan. 11, 1909; 4½ pp.) A brief account of the evolution of the dredge as used in placer work during the past eleven years, with special reference to the Sacramento and Feather river basins. Illustrated. 20c.
- 8459—GOLD DREDGING—The Recovery of Values from River Bottoms. W. D. Egilburt. (Min. Wld., Jan. 16, 1909; 1½ pp.) The author discusses dredging operations, together with the construction of dredges and gold saving devices. 20c.
- 8460—HYDRAULIC MINING—Examining and Fitting Up a Hydraulic Mine. H. A. Brigham. (Eng. and Min. Journ., Jan. 2, 1909; 6½ pp.) The construction of sluices, under-currents, grizzlies, flumes, penstocks and the building of ditches are discussed in detail. Illustrated. 20c.
- 8461—IDAHO—Central Idaho Gold Districts—IV. S. P. Jellum. (Northwest Min. News, Dec., 1908; 4½ pp.) Gives a description of the Orogrande-Fourmile district including its topography, geology and a short description of the operations of the principal mines in the district, the largest of which is the Crooked River Mining and Milling Company. Illustrated. 20c.
- 8462—IDAHO—Central Idaho Gold Districts—V. S. P. Jellum. (Northwest Min. News, Jan., 1909; 8 pp.) The author gives the early history of the district, together with its geology and the economic conditions as they exist. He describes in detail a large number of the principal mining properties in the Buffalo Pump and Newsome districts. 20c.
- 8463—IDAHO—The Coeur d'Alene Mining District. Idaho—III. J. E. Rowe. (Min. Wld., Dec. 5, 1908; 2½ pp.) A historical sketch of the early placer mining, together with a description of a number of quartz mining plants which are in operation at the present time. Illustrated; to be continued. 20c.
- 8464—IDAHO—The Coeur d'Alene Mining District. Idaho—VI. J. P. Rowe. (Min. Wld., Jan. 2, 1909; 3½ pp.) Special mention is made of the Snowstrom Mining Company, giving a plan of their workings. A number of other minor companies in this same district are briefly described. Illustrated; to be continued. 20c.
- 8465—IDAHO—The Coeur d'Alene Mining District. Idaho—V. J. P. Rowe. (Min. Wld., Jan. 16, 1909; 4 pp.) A description of the operations of the Gold Hunter, the Morning mine and a number of smaller companies. Illustrated. 20c.
- 8466—IDAHO—The Coeur d'Alene Mining District. Idaho—VI. J. P. Rowe. (Min. Wld., Jan. 23, 1909; 4 pp.) A description of the operations of the Hecla, Hercules, Helena-Frisco, Standard-Mammoth, Tiger-Poorman, Success, Rex and other mines located in Canyon creek. Illustrated. 20c.
- 8467—IDAHO—The De Lamar Mine of Southwestern Idaho. H. S. Brown and F. B. Mudgett. (Cal. Journ. Technology, Nov., 1908; 5 pp.) A brief historical sketch of the mine and a short description of their 125-ton stamp mill. 40c.
- 8468—LONDON SILVER MARKET in 1908. (Eng. and Min. Journ., Jan. 23, 1909; 1 p.) A review of the prices during the year, together with shipments to India and China. 20c.
- 8469—MEXICO—District of El Chico, State of Hidalgo. K. Thomas. (Mex. Min. Journ., Jan. 9, 1909; 2 pp.) A review of the history of the district and a detailed description of the Aracata, Tetillan and the La Vakarita mines. The author compares the geology of El Chico with that of Pachuca. Illustrated. 20c.
- 8470—MEXICO—Rio Plata Mine and Mill, Western Chihuahua. H. J. Baron. (Eng. and Min. Journ., Jan. 16, 1909; 5 pp.) A description of the development, mining method, ore deposits and the milling plant. Illustrated. 20c.
- 8471—MEXICO—Santa Eulalia Mines, Chihuahua. R. J. H. Merrill. (Min. and Sci. Press, Jan. 2, 1909; 3 pp.) A short history of the early mining operations, together with some notes on the geology in the immediate vicinity. Illustrated. 20c.
- 8472—MEXICO—Some Mining Camps Near Topila, Mexico. T. C. Graham. (Min. Wld., Jan. 23, 1909; 1 p.) An historical review of the district, together with a short description of the work that is now being carried on. 20c.
- 8473—MILL—The Guerrero Mill at Real del Monte, Hidalgo. K. Thomas. (Mex. Min. Journ., Jan. 9, 1909; 2 pp.) A description of the Guerrero mill with flow sheet; the cyanide process and analyses of the Guerrero ore. Illustrated. 20c.
- 8474—MINING METHODS in the North—II. T. A. Rickard. (Min. and Sci. Press, Jan. 9, 1909; 4 pp.) The author describes the various methods and devices that have been employed in the deep-level, non-aqueous, and recovery of the placer gold. He also deals with climatic conditions as affecting the mining industry. Illustrated. 20c.
- 8475—NEW ZEALAND—Alluvial Working at Addison's Flat, New Zealand. A. C. Macdonald. (Eng. and Min. Journ., Jan. 23, 1909; 1½ pp.) A description of a system of hydraulic sluicing and the disposal of tailings by means of a "hack balance" hoist. Illustrated. 20c.
- 8476—NEW ZEALAND—Notes on the Geology of Hauraki Goldfields. N. Z. James Park. (Aust. Min. Stand., Nov. 18, 1908; 1 p.) A description of the famous Waihi lodes, including the Maryana, Crookwell, Tairāwhiti, Royal, Empire, Welcome and Thames. 40c.
- 8477—ONTARIO—The South Loraine Silver District, Ontario. W. B. Phillips. (Eng. and Min. Journ., Jan. 23, 1909; 1½ pp.) A description of a partially developed district which promises future importance. The prospecting so far on a number of claims shows the geology to be similar to that of Cobalt. 20c.
- 8478—ORE TREATMENT at the Giant Mine, Hartley District, Rhodesia. R. C. James. (Journ. Chem. Met. and Min. Soc. of South Africa, Nov., 1908; 4 pp.) The author gives a general outline of the process, which consists of stamp milling with coarse screens, partial amalgamation, fine grinding in tube mills and concentration on blanket and canvas tables, followed by amalgamation. Illustrated. 60c.
- 8479—PLACER GROUND—Testing Placer Ground. A. P. Rogers. (Eng. and Min. Journ., Jan. 23, 1909; 5½ pp.) A short discussion of prospecting by drilling and by test pits. A comparison of the two methods with special reference to the cost and value of each. 20c.
- 8480—PRODUCTION of Gold, Silver and Platinum in 1908. (Eng. and Min. Journ., Jan. 9, 1909; 3 pp.) A review of the influences and the commercial conditions which governed the production and price of the three precious metals. 20c.
- 8481—SILVER PRICES in 1909. Theo. F. Van Wageningen. (Min. and Sci. Press, Jan. 2, 1909; 2 pp.) The author gives in diagram the price of silver from 1902 to 1908 and considers the prospect for amalgamation, very low for the year 1909 as not very bright. Illustrated. 20c.
- 8482—SMELTING—Battery and Cyanide Gold Smelting. A. Thomas. (Journ. Chem. Met. and Min. Soc. of South Africa, Nov., 1908; 3 pp.) A reply to a discussion of the author's paper on this subject which was read at the July Meeting, 1908. 60c.
- 8483—SOUTH AFRICA—The Revival of Mining on the Witwatersrand. Owen Letcher. (Min. Wld., Dec. 19, 1908; 1 p.) Its causes and effects; recent discoveries and amalgamations of interests. 20c.
- 8484—TASMANIA—The Magnet Silver Mine. (Aust. Min. Stand., Nov. 25, 1908; 1½ pp.) An account of the early history, the geology and mining as affecting this country. Illustrated. 40c.
- 8485—TUBE MILLING—Classification for Tube-milling. W. A. Caldcott. (Journ. South African Assn. of Eng., Dec. 1908; 10 pp.) The classification here referred to is one which consists in combining the spitzlute and dewaterer in one classifier, which receives the pulp direct from the tailings launder and de-

livers its coarse sand underflow into the tube mill. 80c.

8486—VICTORIA—The Deepest Gold Mine in the World. Donald Clark. (Aust. Min. Stand., Nov. 18, 1908; 1 p.) A general description of the Victoria quartz mine together with its geology and temperature conditions; also a few notes on mining costs. 40c.

8487—VICTORIA—The Geology of Victorian Gold Occurrence. T. S. Hart. (Aust. Min. Stand., Nov. 18 and Dec. 2, 1908; 3 pp.) Treats of the general geology and classification of the various formations together with a description of the principal auriferous belts. 60c.

8488—WEST AUSTRALIAN GOLDFIELDS at the Close of 1908. Min. Journ., Jan. 9, 1909; 1 pp.) Gives a short résumé of the operations of the principal mines during the past year. Also some notes on climatic conditions, labor and fuel. 40c.

8489—WESTERN AUSTRALIA—Deep Mining at Kalgoorlie, Western Australia. Percy Ifould. (Aust. Min. Stand., Nov. 18, 1908; 2 pp.) A discussion of the prospects and the possibilities of the deep mining at Kalgoorlie. Illustrated. 40c.

8490—WEST AUSTRALIAN MINING PRACTICE—XII. E. D. Cleland. (Journ. W. A. Chamber of Mines, Oct. 31, 1908; 5 pp.) This article tabulates the prevailing wages, the costs of fuel and water, railway freights, the number of men employed, tonnage crushed, gold and silver output and the dividends paid during 1908. Illustrated. 80c.

8491—WYOMING—The South Pass Gold Mining District, Wyoming. Henry C. Beeler. (Min. Wld., Dec. 26, 1908; 2½ pp.) A history of the early mining and development with a description of the power and transportation facilities. 20c.

8492—YUKON DITCH. T. A. Rickard. (Min. and Sci. Press, Jan. 16, 1909; 4 pp.) This article describes the building of a 70-mile ditch by the Yukon Gold Company. It also describes its power plant and gives some data on steam shovel work. Illustrated. 20c.

GRAPHITE

8493—SOUTHERN STATES—Graphite in the South. E. W. Hutton. (Mines, Jan. 7, 1909; 4 pp.) The author discusses and classifies various kinds of graphite and describes a number of deposits in North Carolina, Alabama and other Southern States together with a description of its preparation for market. 20c.

IRON AND STEEL

8494—AUSTRALIA—Iron Ores and Iron Production in Australia. J. Findlay. (Iron Tr. Rev., Jan. 7, 1909; 2 pp.) A short review of the iron industry in Australia in which the author suggests that the future will bring great achievements for the iron industry in this country. 20c.

8495—BLAST FURNACE GASES—Utilizing Blast Furnace Gases at Gary. (Eng. and Min. Journ., Jan. 2, 1909; 2½ pp.) A great power plant to be operated by gases which were formerly considered waste and allowed to escape. The development of the gas engine is also considered. 20c.

8496—BLAST FURNACE PLANTS—Some American Blast Furnace Plants. (Engineer, Jan. 8, 1909; 1½ pp.) The author gives a detailed description of the iron furnaces of the Republic Iron and Steel Company. Also a short description of the Inland furnaces of the Inland Steel Company which are now under construction. Illustrated. 40c.

8497—BRIQUETS—The Manufacture and Use of Iron Briquets. Arvid Johanson. (Jernkontorets Annaler, 1908; 34 pp.) Describes the Gröndal method of briquetting fine iron ores and the advantages of using them in the blast furnace in connection with or instead of ordinary magnetites. 40c.

8498—BRITISH IRON AND STEEL TRADES IN 1908. (Iron and Coal Tr. Rev., Jan. 1, 1909; 7 pp.) A discussion of the commercial conditions during the year, together with statistics of the production, exports, imports and home consumption; also statistics of the output in the various districts. 40c.

8499—CASTINGS—The Manufacture of Steel for Castings. Bradley Stoughton. (Iron Tr. Rev., Dec. 17, 1908; 5½ pp.) A

table of the production of steel in the United States and a discussion of the open-hearth process, temperature of metal, fuel economy and also a discussion of the basic open-hearth process. Special mention is made of the cost of installation of converter and its operation. Illustrated. 20c.

8500—CUPOLA PRACTICE—Latter-Day Cupola Practice. E. E. Rippen. (Foundry, Dec. 1908; 2½ pp.) Deals with the operating of the melting furnace of the gray iron foundry with special reference to sulphur, coke and flux. Also deals with blast and blast pressure. 20c.

8501—ELECTRIC SMELTING—Smelting of Iron Ore by the Electric Furnace in Comparison with Blast Furnace Practice. Joh. Hården. (Electrochem. and Met. Ind., Jan. 1909; 3 pp.) Gives the result of the author's own observations, together with some notes on the design of furnace; also gives comparative results of the two furnaces. A short bibliography on electric smelting is included. 40c.

8502—ELECTRIC STEEL WORKS—The Largest Electric Steel Works. J. W. Richards. (Electrochem. and Met. Ind., Jan., 1909; 1½ pp.) Gives a short description of the plant of the Société d'Électrometallurgie. Procédés Paul Girod, in Ukule, in Savoy, with special reference to the equipment and size of each of the buildings and machinery employed. Illustrated. 40c. 20c.

8503—FOUNDRY IRON—Chemical Specification for Foundry Iron. Geo. C. Davis. (Iron Trade Review, Jan. 1, 1909; 2½ pp.) An abstract of a paper presented before the Philadelphia Foundrymen's Assn., Dec. 2, 1908, in which the author discusses the sulphur, carbon and silicon content in foundry castings. 20c.

8504—GEORGIA—Clinton or Red Ores of Georgia. E. C. Eckel. (Iron Tr. Rev., Jan. 7, 1909; 1½ pp.) A discussion of the distribution and geological relations of the red ores, together with the character and thickness of the beds and an estimate of the reserve tonnage in Georgia. A short discussion of their origin. Illustrated. 20c.

8505—HARDENING—Barium Chloride for Hardening Steel. Ethan Vail. (Am. Machin., Jan. 7, 1909; 2½ pp.) Design of furnace, heating and composition of barium mixture, cost of operation, method of suspending work and the results obtained. Illustrated. 20c.

8506—IRON AND STEEL INDUSTRY in 1908. (Eng. and Min. Journ., Jan. 9, 1909; 7 pp.) A year of deep depression and small demand with only gradual recovery. A discussion of an attempt to revise law of supply and demand. Also statistics attending the production of iron. Illustrated. 20c.

8507 LAKE SUPERIOR—The Great Iron Fields of the Lake Superior District—VII and VIII. Robert B. Brinsmade. (Min. Wld., Dec. 31 and Jan. 7, 1909; 2½ pp.) The present instalment deals with the conditions and mining methods as found in the Mesabi and Marquette ranges, Minnesota. Also a note on quicksand shaft sinking. 40c.

8508—MAGNETITE DEPOSITS of the Cornwall Twp. in Pennsylvania. C. Spencer. (Bull. 359, U. S. Geol. Surv., 1908; 102 pp.) The author gives the geology of eastern Pennsylvania and a general description of the ore deposits. A good reference book. 20c.

8509—MALLEABLE CASTINGS—Production of Malleable Castings—X. R. Moldenke. (Iron Tr. Rev., Jan. 21, 1909; 4 pp.) The author discusses the use of pig iron in the open hearth furnace for melting iron for malleable work. He also gives a description of the Morgan gas producer showing the coal and ash handling equipment. Illustrated. 20c.

8510—MESABI RANGE—Work Done During 1908 at Mesabi Range Mines. O. J. Abell. (Iron Tr. Rev., Jan. 7, 1909; 7 pp.) A review of creditable achievements during the year together with notes on sinking concrete shafts. Also an account of the methods used in stripping the ore deposits. Illustrated. 20c.

8511—NORTHWEST—Iron Ore Deposits of the Pacific Northwest. H. C. Estep. (Iron Tr. Rev., Jan. 7, 1909; 4½ pp.) A description of the deposits of the Safford iron mine, Barkley Sound, Vancouver Island. Also a short description of the deposits on Texada Island. Also a table of analysis of iron ores of this district. Illustrated. 20c.

8512—PRICES—Fluctuations in the Prices of Iron and Steel Products, 1899-1908. (Iron Age, Jan. 14, 1909; 3 pp.) A tabulation of the prices by months together with a chart showing the fluctuations. 20c.

8513—ROLLING MILL PLANT—New Gas-Driven Rolling-Mill Plant at Mossend Works. (Engineering, Nov. 27, 1908; 1½ pp.) A description of the Mossend steel works in which the plant has been entirely remodeled. Special mention is made of their reheating furnaces, rolls and the power house. 40c.

8514—STEEL CASTINGS in Small Quantities. A Simons. (Iron Age, Jan. 14, 1909; 2½ pp.) From a paper read before the Philadelphia Foundrymen's Assn., Jan. 6, 1909, in which the author discusses the manufacture of castings in a converter of 1000 lb. capacity. 20c.

8515—STEEL INGOTS—Piping in Steel Ingots. J. F. Springer. (Cassier's Mag., Jan., 1909; 18 pp.) A discussion of the methods for its reduction and elimination. Illustrated. 40c.

8516—STEEL MILL EQUIPMENT—Gas-Electric vs. Steam Equipment for Steel Mills. J. A. Knesche. (Iron Tr. Rev., Jan. 7, 1909; 6½ pp.) A discussion of the question whether it pay to discard good steam equipment and place it with gas-electric equipment. The author analyzes the requirements and estimates the power to be derived from four blast furnaces, together with tables showing cost of equipment and the amount saved by utilizing the furnace gases. 20c.

8517—STEEL PLANT—The Works of the Indiana Steel Company at Gary, Ind. (Iron Tr. Rev., Jan. 7, 1909; 22 pp.) The first of a series of articles describing the great plant which the Steel Corporation is building on the shore of Lake Michigan. The present article is descriptive of the blast furnace equipment. Illustrated. 20c.

8518—TENNESSEE—Iron Operations in the Chattanooga District. Edwin Higgins. (Eng. and Min. Journ., Jan. 2, 1909; 5 pp.) A general description of the conditions of this district as compared with Birmingham. An outline of the operations of the Roane Iron Company and the Dayton Coal and Iron Company. Illustrated. 20c.

LEAD

8519—ANALYSIS—Refined Lead Analysis. Broken Hill Proprietary Company. Leslie Bradford. (Aust. Min. Stand., Nov. 18, 1908; ¾ pp.) A description of the method employed at Broken Hill for analyzing for refined lead, with special reference to determining zinc, antimony and copper. 40c.

8520—ANALYTICAL METHOD—Chromate Method for the Determination of Lead in Ores, Etc. A. H. Low. (West. Chem. and Met. Dec., 1908; 4 pp.) Contains a detailed statement of the method used by the author which is stated to be fairly short, easy of manipulation and gives very accurate results. 80c.

8521—LONDON LEAD MARKET in 1908. (Eng. and Min. Journ., Jan. 16, 1909; 1 p.) A résumé of the market conditions for each month of 1908. 20c.

8522—PRODUCTION OF Lead and Spelter in 1908. (Eng. and Min. Journ., Jan. 9, 1909; 10 pp.) Statistics of the production and price; imports and exports; a review of the mining conditions of the markets and the production of zinc oxide. Illustrated. 20c.

8523—SMELTING PRACTICE at Granby Works, Missouri. Evans W. Buskett. (Min. Wld., Dec. 19, 1908; 1½ pp.) A description of the Scotch hearth furnaces used to smelt lead concentrates. Treatment of the smelter fumes for the recovery of lead. Illustrated. 20c.

MANGANESE

8524—ARKANSAS—Manganese Ore in Arkansas. E. C. Harder. (Min. Wld., Dec. 26, 1909; ¾ pp.) A brief description of the geological occurrence of manganese, together with the names of a number of the more prominent operators. 20c.

PETROLEUM

8525—ADULTERATION of PETROLEUM PRODUCTS. (Iron Tr. Rev., Jan. 2 and 16, 1909; 3 pp.) A discussion of

8568.—ORE DEPOSITION—Experiment on the Separation of the Constituents of a Solution by Filtration Through a Mineral Filter. Eugene C. Sullivan. (*Eng. Geol.*, Dec., 1908; 7 pp.) A series of

periments to show the effect of rock-wall dilution of mineralized solutions as bearing upon ore deposits. 60c.

MINING—GENERAL

8569—ACCIDENTS—Industrial Accidents. F. L. Hoffman. (Bull. Bureau of Labor, No. 78, Sept., 1908; 49 pp.) A general discussion of the frequency and causes of accidents in the United States giving statistics of fatalities in the various industries, including iron and steel manufacture, coal and metal mining, smelting and refining. 45c.

8570—ALASKA and the Yukon. T. A. Rickard. (Min. and Sci. Press, Jan. 2, 1909; 8 pp.) A review of the mining conditions of Dawson and the Klondike; of Fairbanks and Tenana Valley and also of Nome and the Coastal Plain. Also statistics of the mineral output. Illustrated. 20c.

8571—BRITISH COLUMBIA—Progress in British Columbia. G. A. Ohren. (Can. Min. Jour., Jan. 1, 1909; 1 p.) The author gives some statistics regarding the output of the principal mines in this province. 20c.

8572—BRITISH COLUMBIA—South-eastern British Columbia. G. A. Ohren. (Can. Min. Jour., Jan. 1, 1909; 3 pp.) A summary of the mining industry in the year 1908, with reference to the mining laws, transportation, markets, labor conditions and a short description of the Boundary, Rossland and Nelson districts. 20c.

8573—CALIFORNIA—Mineral Production of California. (Bull. No. 53, Cal. State Min. Bureau, 1908; 82 pp.) Gives statistics of the various minerals and metals produced in the State during 1907. 20c.

8574—COLORADO—The Non-Metallic Minerals of Colorado. John C. Bailar. (West. Chem. and Met., Dec., 1908; 7 pp.) Deals principally with the clay deposits and brick industry, but also mentions the minerals with the mention of a few other non-metallic minerals. 80c.

8575—COMPRESSED AIR in Mining. (Min. Sci., Jan. 7, 1909; 1½ pp.) The author discusses some of the essential points to be considered in selecting a compressor for mining work. 20c.

8576—COMPRESSING AIR—A Cheap, Efficient Method of Compressing Air. Jos. H. Hart. (Min. Wld., Dec. 5, 1908; 2½ pp.) A description of mechanical refrigeration and its use in compressing air for mining purposes which claims to give greater efficiency than is obtained by the Ingersoll-Sargeant and Rataan systems. 20c.

8577—CONSERVATION OF RESOURCES—Our National Resources, Their Conservation and Utilization. John Birkinbine. (Journ. Frank. Inst., Jan., 1909; 21 pp.) The author points out that our resources must be considered in relation to the rapidly growing population. He discusses our coal, iron and forests. 60c.

8578—DEVELOPING A MINE for Sale to a Company. J. B. Wilson. (Aust. Min. Stand., Nov. 18, 1908; 1 p.) A statement of the data required by engineers to enable them to intelligently offer a prospect for sale. 40c.

8579—DRILLING—Important Features of Diamond Core Drilling—I. C. J. McCord. (Min. Wld., Jan. 2, 1909; 3½ pp.) First of a series of articles giving a historical account of drilling. Together with a description of the outfit required. Special mention is made of its use in the zinc and lead industries of Missouri and the Lake Superior districts for iron and copper. Illustrated. 20c.

8580—DRILLING—Some Features of Diamond Core Drilling—II. C. J. McCord. (Min. Wld., Jan. 9, 1909; 2½ pp.) A discussion of the various grades of carbon, together with the methods of setting the diamonds in the bits. Illustrated. 20c.

METALLURGY—GENERAL

8603—BIBLIOGRAPHY OF CHEMISTRY—A Select Bibliography of Technical Chemistry. (Chem. Engr., Dec., 1908; 24 pp.) Gives the names of works on the various branches of chemistry, with dates of publication and prices; contains also some works of purely mechanical and electrical nature which are likely to be of interest to the chemical engineer; does not include any books of

foreign languages nor works out of print. 40c.

8604—DESULPHURIZING—The Carmichael-Bradford Desulphurizing Process. (Aust. Min. and Eng. Rev., Dec. 5, 1908; 2 pp.) The description of a process which economically effects the rapid and thorough desulphurizing of sulphide ores, and converts the same into a suitable physical condition for smelting. Illustrated. 40c.

8605—MELTING—Experiments on Melting in the Induction Furnace. F. A. J. Fitzgerald. (Electrochem. and Met. Ind., Jan., 1909; 1 p.) Gives the description of the method used and a comprehensive table showing the time and energy consumed during the operation. Illustrated. 40c.

8606—METALLOGRAPHY—Notes on Metallography. W. G. Haldane. (West. Chem. and Met., Dec. 1908; 11 pp.) Deals with metallography in a general way, giving cooling curves and freezing point diagrams of molten metallic solutions. Illustrated. 80c.

8607—PHOSPHOR BRONZE—Notes on Phosphor Bronze. A. Philip. (Metal Ind., Dec., 1908; 2½ pp.) These notes are a record of chemical and mechanical tests, with the view of arriving at some general provisional conclusion as to the most desirable chemical specification for this material. 20c.

8608—REFRACTORIES—Selection of Refractories. (Iron Tr. Rev., Jan. 7, 1909; 9 pp.) A consideration of the kind and quality of brick best suited for various parts of different furnaces. Illustrated. 20c.

8609—SILUNDUM, a New Product of the Electric Furnace. F. Bölling. (Electrochem. and Met. Ind., Jan., 1909; 1½ pp.) An illustrated description of the method employed in making silundum (silicified carbon), its properties and uses. 48c.

8610—SMELTER SMOKE. J. W. Neill. (Min. and Sci. Press, Jan. 9, 1909; 1 p.) A short review of the recent developments in solving the smelter smoke question. 20c.

MINING AND METALLURGICAL MACHINERY

8611—BITUMINOUS PRODUCER PLANTS. Elbert A. Harvey. (Journ. A. S. M. E., Jan., 1909; 15 pp.) A discussion and a description of an industrial gas plant using Indiana bituminous coal. Includes some notes on the cost of gas and its efficiency.

8612—CONVEYING OF MATERIALS. C. Kemble Baldwin. (Journ. A. S. M. E., Jan., 1909; 10 pp.) This paper has special reference to the design of belt conveyors for handling heavy and abrasive materials, and gives some data which will be of service in the preparation of preliminary designs.

8613—DEPRECIATION OF MACHINERY. J. E. Darbishire. (Engineering, Oct. 23, 1908; 12 pp.) Discusses maintenance, depreciation and the treatment of machinery and various faults in keeping the books of manufacturing companies wherein these items are not properly treated. Illustrated. 40c.

8614—DUST-FLUE—Neuere Gesichte punkte beim Bau der Hüttenrauch-Kondensationsanlagen. (Oest. Zeit. f. B. u. H., Oct. 24, 1908; 2 pp.) Describes a dust-flue with a trap shape containing a longitudinal scraper-conveyor for extracting the dust. 40c.

8615—ELECTRIC FURNACES—Recent Developments of the Kjellin and Rösching-Rodenhauser Electric Induction Furnaces. (Trans. Am. Electrochem. Soc., Oct., 1908; 12 pp.) A discussion of the development of the electric induction furnace during the last two years, together with a description of this new furnace and the results obtained therefrom. Illustrated. 40c.

8616—ELECTRICITY IN MINES. Joseph D. Griffin. (Aust. Min. Stand., Nov. 4, 1908; 1½ pp.) A discussion of the advantages of electricity, its simplicity and the saving of labor in the operating department of the North Mount Lyell mine. Illustrated. 40c.

8617—EXCAVATORS AND CONVEYERS—Moderne Verladekrane, Gebaut von Adolf Ebert and Company in Leipzig. Adolf Ebert and Company. (Zeit. des Vereines Deutscher Ingenieure, Oct. 31, 1908; 8 pp.) Describes, with numerous shop drawings, several kinds of scoop ex-

cavators and the cranes for operating them for handling ore, coal, etc.

8618—FACTORS OF SAFETY. A. S. Osterlicher. (Journ. Transvaal Inst. Mech. Engrs., Dec., 1908; 5 pp.) The object of this paper is to investigate the points upon which the safety of a correctly designed structure or a piece of machinery depends. The author discusses the properties and strengths of materials. Illustrated. 60c.

8619—GAS FURNACE—The Loder Oxygen Gas Furnace. Will C. Higgins. (Salt Lake Min. Rev., Dec. 15, 1908; 2 pp.) A description of a gas furnace in use at Nelson, Escondido Canyon, Nevada. It is claimed that the highly silicious charges can be run than with the other types. Illustrated. 20c.

8620—GAS PRODUCER PRACTICE—Notes on Anthracite Producer Practice. George C. Stone. (Journ. Ind. and Eng. Chemistry, Jan., 1909; 2½ pp.) Describes a series of experiments made to improve the practice at one of the author's plants. The experiments included change in the size of fuel and reconstructing the producers. 60c.

8621—HYDROELECTRIC PLANT—Dalmatian Carbide Works Using 30,000-Volt Generators. F. Koester. (Elec. Rev., Jan. 9, 1909; 4 pp.) A description of the Manodolac power plant, a generating room switchboard and transmission system. Illustrated. 20c.

8620—PRODUCER GAS—Gas-Firing and the Advantages of Gas-Firing Over the Direct Use of Coal. Ernest Schmatz. (London, Jan. 1909. Published by the author, 16 pp.) Compares direct and gas firing, boiler firing, lime kiln firing, reverberatory furnaces, etc. Illustrated.

8621—PRODUCER GAS—Moisture in Producer Gas. J. MacFarlane. (Iron and Coal Tr. Rev., Nov. 27, 1908; ¾ pp.) A tract of paper before the West of Scotland Iron and Steel Institute. Gives calculations made by the author to illustrate the effect of moisture on the thermal efficiency of producer gas.

8622—PUMPS—Experiments with Two Electrically-Driven Pumps. Thomas Lindsay Galloway. (Trans. Min. Inst. Scot., Aug. 8, 1908; 11 pp.) These experiments were made with a view to testing a new valve pattern, which was subsequently extended for the purpose of ascertaining the relative merits of this type of pump and a reciprocating pump of the triple-ram pattern, each working under varying condition of load.

8623—SWITCHBOARDS for Mine Power Plants. W. B. Clarke. (Mines and Minerals, Nov., 1908; 2½ pp.) Describes the equipment desirable and the reasons for certain arrangements. Illustrated. 20c.

8624—TUBE MILL LININGS—Honeycomb Tube Linings. H. P. Barry. (Aust. Min. Stand., Dec. 2, 1908; 1 p.) The author describes a patent method of securing any hard rock in tube mills or other grinding machines without costly and sometimes impossible preliminary work of dressing the material. Illustrated. 40c.

8625—WATER POWER—Pressure Fluctuations in Turbine Pipe Lines. A. Budan. (Journ. Assn. Eng. Soc., Oct. 1908; 30 pp.) Discusses the problem of utilizing water power and devices used to draw it together with some theoretical investigations by the author. Illustrated. 40c.

ANALYTICAL CHEMISTRY

8636—BARIUM—A Volumetric Method for the Determination of Barium. A. E. Hill and W. A. H. Zink. (Journ. Am. Chem. Soc., Jan., 1909; 6½ pp.) The method here proposed depends upon the precipitation of barium as iodate and upon the oxidal action of this compound on an iodide solution, with subsequent titration of the free iodine with sodium thiosulphate. 80c.

8627—SILICA—The Determination of True Silica in Zinc Residues. R. S. Beall. (West. Chem. and Met., Dec., 1908; 2 pp.) Simply and application of the method used in the author's determinations. 80c.

INDUSTRIAL CHEMISTRY

8628—SULPHURIC ACID—W. W. Wilke. (Drugs, Oils and Paints, Dec., 1908; ½ pp.) A discussion of the development and application of the contact process for manufacturing sulphuric acid as patented by the Verein Chemischer Fabriken in Mannheim, Germany. 20c.

Industrials

The Coahuila Mining and Smelting Company, Ltd., of Viesca, Coahuila, Mexico, will be interested in receiving descriptive literature on pneumatic ore-separating machinery.

McClintic-Marshall Construction Company, designers, manufacturers and erectors of steel buildings, bridges, etc., Pittsburgh, Penn., has opened an office in 839 Central building, Seattle, Wash. C. F. Boyce is the sales representative in charge.

The Youngstown Car Manufacturing Company, builders of ore and mining cars, has recently moved its Chicago office and is now located at 1603 Fisher building. The office is in charge of Charles B. Owens, formerly of the American Car and Foundry Company.

Wm. Ainsworth & Sons state that they have received an order for three 18-in. precision wye levels and two 6-in. precision transits from the Aqueduct commission in charge of the construction of the Los Angeles aqueduct, awarded chiefly on account of the interchangeability of parts, rigidity and workmanship.

The South Scranton tunnel of the Scranton Gas and Water Company is 4200 ft. long and 7x10 ft. in section. All of the drills (16 in number) used on this extensive piece of work were furnished by the Wood Rock Drill Company, of Paterson, N. J. They were only used after being in active competition with the drills of other manufacturers.

The Dearborn Drug and Chemical Works reports that the general business of the company for the last six months of 1908 was larger than for any other six months in its history, indicating the quick return of prosperous business conditions. The percentage of increase the past six months, and especially for January, in the eastern department of the company, is particularly gratifying.

Robert W. Hunt & Co., consulting and inspecting engineers, has engaged the services of John Cargill, who will make his headquarters at the firm's New York office, 90 West street. He will largely devote his attention to the examination and report upon railway and other corporate properties, for which his experience gained while connected with the Pennsylvania lines, British Westinghouse, Metropolitan Railway Company of London, and other organizations, has prepared him.

The Cyclone Drill Company has rented offices in Chicago. In the past few years the company has secured a large portion of its business from Chicago from mining properties in the North and West. The business from that point having grown to such an extent it was recently decided to open an office there to take care of the trade to better advantage for both the customers and the company. J. F. Munn, who has had charge of the core drill department at the factory for several years, will take charge of the Chicago office. Mr. Munn has had a very broad experience in drill work, covering both core and churn drilling, and his experience will be valuable to the buyers of prospecting machinery. R. R. Sanderson will succeed Mr. Munn at the Orrville office. The Chicago address of the company is 419 Fisher building.

The U. S. Flexible Tubing Company, whose San Francisco establishment has been temporarily located at Beale and Mission streets, has now moved to its permanent location, 63 and 65 Main street, San Francisco, Cal. The new quarters will enable the company to care for the wants of its patrons promptly. The new establishment will afford considerable space required to handle the long lengths of metal hose for installing connections and the testing of same, as the company will not allow metal hose to leave its establishment without being subjected to a thorough test. The popularity of metal hose is ever increasing and with

it the company endeavors to meet the demand. The new quarters will also enable it to carry a larger stock of metal hose so as to meet all requirements. A cordial invitation is extended to all the company's friends to call at its new establishment.

A complete line of air compressors as built by the Thos. H. Dallett Company, of Philadelphia, Penn., brings out many excellent and unique ideas in compressor design. The frame is of the open-fork center crank type, and of an especially massive and rigid design to obtain on each size compressor a greater range of capacity by substituting, when desired, a cylinder of the next larger size than the standard to operate at 100 lb. pressure. For example: On an 8-in. stroke compressor the regular cylinder for 100 lb. pressure is 8 in. in diameter, but a 10-in. diameter cylinder can be substituted and still operate at the above pressure, whereby a greater volume of air is obtained with but a slight increase in cost of machine. In the case of duplex compressors with compound steam cylinders, a difficulty has been, if the machine stops with the high pressure side on the dead center, which occurs frequently, it will not start automatically, this being due to the fact that but one side (the high pressure) takes steam from the line. This trouble has been overcome by using a reducing valve of standard make, which reduces the live steam pressure for use in the low pressure cylinder, thus if the high pressure side stops on the dead center, live steam is fed to the low pressure cylinder through the reducing valve, starting the compressor. It is obvious that steam from the boiler is taken into the low pressure side only when starting, otherwise the operation is identical with any compound machine. The cross head is a new-type box pattern, made of semi-steel. Its shoes are adjustable and of large bearing surface. The upper shoe is lubricated by means of a sight-feed lubricator, and the lower shoe runs continually in a bath of oil. One of the features of this design is the side openings, which allow easy access to the cross-head shoe binder bolts. The cross-head pin is tool steel, hardened and ground. It is fitted to tapered seats in the cross-head, drawn tight on the tapers by means of a nut held in position by a pin. Means are provided for turning one-quarter revolution in case it wears flat on the two bearing sides, thus doubling the wearing capacity. The air intake and discharge valves have been given most careful consideration, and are special features of these compressors. The intake valve is of the automatic poppet type, contained in a malleable-iron cage. The cage is one piece, and combines both seat for the valve and guide for the valve stem. The cage is threaded and screws into the wall of the air-intake chamber only, and is simply seated in a recess on the main cylinder wall, using thin corrugated copper gaskets to secure a tight joint. A hexagonal recess has been cast in all cages to accommodate a special cast-steel wrench for use in removing and replacing valve cages. The valve cage cap acts as a lock nut for holding the cage in place after it has been screwed down on its seat in the cylinder. It is provided with a hexagonal projection, and the same wrench can be used here as on the valve cage. In the case of compound machines, corrugated copper gaskets are placed under the valve cage caps on the high pressure cylinder to insure against any leakage, as the discharge pressure from the low pressure cylinder is constantly at these joints. The valve proper is a special alloy-hardened steel, with seat and stem ground to gauge. The valve spring is of phosphor bronze and of the right proportion to give the valve an easy opening and a quick closure. Much annoyance and trouble has been caused on certain makes of intake valves due to the spring holder shearing off or working loose. The cause of this trouble is due to the sudden stopping of the valve on its seat, which tends to drive the spring holder off the valve stem. This effect may be likened to driving a hammer on its handle by

means of hitting the handle on its opposite end. The principle involved is identical. To eliminate this defect and the trouble caused by threading and pinning the spring holder to the valve stem, solid ends have been employed by some builders, which necessitates a split guide and complicates the valve parts. On the "Dallett" valve the spring holder comprises a split taper ring set in a recess on the valve stem and held together and tight to the stem by means of a solid taper ring slipping down over it. The hammering of the valve on its seat tends to tighten the spring holder on the stem instead of driving it off, due to the action of the taper. The discharge valve is of the automatic poppet type contained in a valve cage of malleable iron. The method of seating in the cylinder and locking in its seat is identical with that of the intake valve. A projection or boss has been provided on the valve cap which acts as a positive stop for the valve when it has reached a lift giving a full opening area, and does away with fluttering. This same projection on the cap also acts as a spring guide for the valve spring. The intercooler plays a very important part in economical operation of a two-stage machine. The "Dallett" intercooler is of large cooling area, employing the return-flow type of water circulation, using baffle plates to deflect the flow of air and aid in its effectual contact with the cooling tubes. This method is very efficient in reducing the temperature of the air between stages to approximately the original temperature, thus tending to reduce the final or discharge temperature and also the horsepower required for a given capacity. The nest of cooling tubes may be removed intact from the intercooler box without disturbing any of the piping, as unions are supplied to obviate this feature. The intercooler is supplied with pop safety valve, pressure gauge and drain valve. In a compressed-air plant the demand for air is often of such an intermittent character that automatic regulation of the supply of air in accordance with the demand becomes a necessity. The belt-driven machines are provided with an unloading device which automatically unloads the air cylinder. When a certain determined pressure is reached in the air receiver, one or more inlet valves at both ends of the air cylinder are held open and the load is taken off the compressor, allowing it to run light until the pressure drops in the receiver, upon which the valves are released and air compression is resumed. On the steam machines, a combined speed and pressure governor is used. This governor unloads the air cylinder exactly the same as on a belt-driven machine, and at the same time it controls the speed, allowing a single steam machine to just turn over when unloaded, and bringing a duplex or compound machine to a dead stop. By this means a great saving in steam is effected and the wear and tear on the working parts, as in the case of continuous running machines, is reduced. A complete unloading equipment is furnished with all machines. The compressors described are built in sizes from 8-in. stroke up to and including 16-in. stroke, and give a range of capacity from 79 cu.ft. of free air per min. to 1200 cu.ft. Special machines for any capacity, pressure or service, or any standard machine direct connected to motor, water wheel or gas engine, can be furnished in addition to the standard line.

SMOOTH-ON
CEMENTS

"Mining camps should keep *Smooth-On*." It's the next best thing to a fully equipped foundry. In fact it's often *better*, as it permanently makes repairs *in place* and saves knocking the machinery or piece apart. No long delays, no transportation charges.

Smooth-On Iron Cement is applied as a paste or putty and expands when metallizing. When hard, it stands red heat, steam pressure, water or oil, expands and contracts with the metal and lasts as long as the piece to which it is applied. Use it for *first and final aid* to leaky boilers, tank or pipe connections, cracked pumps and the thousand and one other repairs which are continually springing up.

Write for Instruction Book No. 7—a little volume full of hints and helps on *repairing*.

T. E. Co. Concentrating Table

The Concentrating Table which we are presenting to the users of metallurgical machinery is superior in every particular to those offered by our competitors. We can satisfy you of this fact if you will give us the opportunity. We will not only tell you what we claim for this table, but will give you proof of what our customers think of the Traylor Table.

(EXTRACT FROM LETTER)

"The Traylor Table has run with but few periods of shut-down, and has required repairing to a very much less extent than that required by tables of other make with which the mill is provided. The table appears **best adapted to handle a pulp intermediate in size of grain between that ordinarily treated by tables and vanners.** With that kind of a feed, the mill men prefer to run the Traylor Table."

Every one who has used and are using the Traylor Table speak of it in terms as highly complimentary as the mill manager who made the above statement. Give us an opportunity to prove that our claims are justifiable. Write to us for our catalog on the Traylor Table and let us give you prices.

Where the House Organ Falls Down

Being a Sermonette Letter from Our Old Man to a Sales Manager Who Solicited an Advertisement for His Own Pet Scheme

DEAR SIR:—We have your letter soliciting our advertising for your house organ, and in reply submit the following heart-to-heart talk on the whole subject:

We do not advertise in house organs for a great many reasons.

One reason is that if we advertised in one, we should in all, and this would be impossible, because there are too many.

Like the styles, the croup and the pip, the house organ becomes fashionable about once in seven years—it is epidemic now.

The house organ is no more a newspaper than any other of the owners' circulars. It is made to look like one, and those little versed in engineering publications are sometimes fooled—but the publisher most of all.

The trouble with the house organ is insurmountable—it holds a brief for the concern that publishes it.

The real trade paper holds a brief for its readers, and is published in their interests.

That is why the best men in its line pay for the real paper, read it and trust it.

No house organ, given away in the trade, can ever hope to be more than another piece of advertising for the house, and biased in favor of the products of the house.

If it were not there would be no use in sending it out.

Your paper may attract some attention from the people to whom you give it; but attention is not an offer of marriage, as many another flirt has found out.

We believe that everything in this world is appreciated at about what it costs—house organs cost the reader nothing directly.

A house organ sent free to a busy man responsible for results somewhere in the engineering world is something like an unbidden guest at his daughter's wedding.

The technical paper he takes and has taken for years is an old friend. Invited? Yes, and to supper afterward, and to stay all night, and over Sunday.

The house organ man is not the only one who misunderstands. There are lots of advertisers who think, and say, that they support the papers—and some publishers know no better.

But the truth lies a little farther on. The subscriber pays the publisher directly just about the price of white paper. But he pays all the advertiser puts up for advertising as well.

Advertisers expect to get back all they pay for advertising, and more—who can pay it except those who read the adver-

tising and invest their money in the goods advertised?

And this pays the advertiser in more ways than one. Goods that are continuously advertised are better than others, because they could not be kept on the market if they did not give satisfaction. Advertisers make more goods than non-advertisers and it costs them less to sell—all to the buyer's profit.

That's why we keep our hats off to the readers of our papers, and that's why the advertiser should take off his hat to the same good customers.

Very few thinking men believe now that the landlord, and not the tenant, pays the taxes on property—the landlord pays them only when the property is vacant.

When any machine-building concern issues a house organ we are sorry, not so much because it may cut into our revenue, but because it shows that that concern has not yet learned the difference between publicity and advertising—between printing and publishing.

You can get publicity by eloping with the cook—but it isn't advertising.

You can make a house organ that looks just like the AMERICAN MACHINIST, but it is only printing—not publishing.

Publishing is a fruit tree of slow growth, and only begins to bear after years of cultivation and care—not a Johnny-jump-up that blooms every year you scatter some seed.

It takes years to build up confidence in a trade or technical paper to a point where the busy man finally depends upon that paper to sift out the news of his business, or some part of his business, and present it to him, partly digested.

It takes years for him to know that it will find and show up the new processes in his business, the new machines, the new materials, and come to his hand weekly with a condensed catalog of all the machinery and appliances that he needs in his plant.

It takes years to make him feel that it is unbiased, above board and fair, and that if he reads it regularly he need not worry much about something important getting by him that he should have known about.

Every manufacturer, every important man of affairs, depends on some paper in that way.

Some papers deserve and some only partly deserve this confidence, but the house organ never gets there and never can.

It's masquerading as a newspaper—is in itself an insinuation to the intelligent

man that he doesn't know the difference—he does, and you cannot afford to lose his friendship.

We need say little of those "near" house organs that print a few pages of slush, totally foreign to the subject, and wadded between a few pages of ads for the owner. Curiosity may cause some of the right people to look at them for a time or two, but with never a thought of business. They only go to show how little some manufacturers know about advertising and how easy they are influenced by their amateur organ grinder.

The same money spent in regular, established papers will insure better returns, and work with the grain, not against it.

The same newsy matter, your shop news, now saved up for the house organ, in your regular space in the real paper will make that space twice as effective.

Why do manufacturers let their advertising men write newsy, interesting stuff in the house organ and have a fit if they see it in their paid-for space?

Some of the house organ publishers are the very people who say that there are too many trade papers now.

Yet they propose to have a paper for every shop—not one or two for every trade.

There are about twenty house organs in the lines of our three engineering papers; most of them less than a year old. If each of these can get an ad. from the other, and all from the trade papers and other manufacturers, the breed will multiply like rabbits, nobody will read any of them, and the trade paper will wish it hadn't kept still so long.

The establishment of a house organ taking ads. from the trade for free distribution is bad enough, but asking those papers that have been built up by years of labor and investment of money to advertise in them is just as attractive a proposition to a publisher as it would be to you if we published article after article advising people not to buy your machines, but to build them themselves.

Any house organ is a circular for the concern that sends it out, masquerading under the guise of a trade paper, and assuming that the people that get it don't know what they are driving at.

Assuming that any customer is a fool, is, we believe, not now taught as "good form" in any school of salesmanship.

When you see our advertising in any house organ, clip it out and send it in and we will give you one just as big.

BRIQUETTING MACHINERY

**CONVERT YOUR FINES
INTO LUMP ORE.**

Chisholm, Boyd & White Company,
Chicago, Illinois, U. S. A.

Coal and Ore Briquetting Machinery

Patented process and machinery designed and built to meet American conditions. Low cost of operation. Same equipment will produce different sizes of briquettes. Can use either melted or crushed pitch for binder. No experiment. Complete plants erected.

Mashek Engineering Company,
141 Broadway, New York.

WHAT'S TOO SMALL TO HAND PICK IS TOO LARGE TO LOSE

The McLanahan Ore Jig saves the fines. It's rank folly to lose the values contained in your ore-bearing mud. The McLanahan machinery and Ore Washing Devices will net you a steady income. Write for catalog.

McLanahan-Stone Machine Company,
Hollidaysburg, Pa.

There's A Vast Saving

of gold Values that ordinarily pass out from below your plates and traps.

The **PIERCE AMALGAMATOR** saves all your flour gold by its installation. Be alert—stop the leaks, it's money in your pocket.

*Catalog "F" tells the story.
Write for it to-day.*

When You Need A PRACTICAL Reference Work

—you need a work that will give you the best up-to-date modern practice—not long-winded obtruse theories, but the every-day practice in use by the best mining experts—clearly stated facts that can be easily and quickly understood, remembered, and applied. There is no other reference mining work in the world that can meet this description so well as the International Library of Mining. This is an epitome of the years of experience of the best mining experts in the country edited in a style that 17 years of experience in publishing home-study textbooks has proved the easiest to learn, to remember, and to apply. The 13 volumes of this Library are part of a series of textbooks that cost \$1,500,000 to prepare. They are recommended by the highest authorities and are used in nearly all of our leading universities and colleges. They treat of practical mining and mining methods, starting from the simplest problems and comprehensively covering the whole science of mining both for coal and metal mines. Not only can they be used to great advantage by mine owners, mining engineers, and mine officials, as an authoritative guide in their business, but since they can be clearly understood by all persons having no knowledge of higher mathematics, they can be used by all classes of mine workers who are desirous of advancing their positions and bettering their salaries.

Our free booklet together with full description of this Library will be sent to any person sending us the coupon below.

Hadn't you better send it NOW before you forget it?

The Engineering and Mining Journal
American Machinist Power and The Engineer

THIS book is devoted exclusively to mining methods. Mr. Mayer covered the most important British and European mining sections, making a comprehensive study of the mining problems and methods with a view to their adoption in America.

Despite the fact that our American methods are clearly traced to foreign origin, little is known of advanced European methods in this country and in the same way there is little intercommunication between different foreign States and countries owing to variations of language and dialect.

The book places the latest information at the disposal of mining engineers and mining men. It is a most valuable piece of work and of the greatest importance to the mining man who seeks more economical and practical methods.

The illustrations from photographs taken in the mines by the author are a striking feature.

Description of Contents

Among many valuable sections, the following deserve special emphasis:

The "caving" system, as employed at its birth-place, Cumberland, England.

The great sea barrier at Hodbarrow, England, by which the Irish Sea is held back and rich iron ore extracted within its area.

The spectacular underground methods employed in Wales, the great heights attained by ladders, supported tent-pole fashion, and the grappling with many hazardous conditions with supreme confidence.

The Longwall system, much neglected in America. The English and French use it extensively and successfully under a great variety of conditions.

Robbing of high pillars with treacherous roofs and without timber accomplished with great skill in many places.

The keynote of the book is the highest efficiency in extraction, with the greatest economy, that valuable material shall not be left in pillars instead of going to the markets.

The Chapter Headings

Part I—Mining in Great Britain

Mining in Great Britain. Parkside Mine, Cumberland. Crago Moor Mine, Cumberland. Ulloa Mine, Cumberland. Hodbarrow Mine, Cumberland. Longwall Methods of Mining Flat Seams. Sention-Belaval Colliery, Northumberland. Chopwell Colliery, Northumberland. Kimblesworth Colliery, Northumberland. Wathol Colliery Midland District. Coal Mining in South Staffordshire. Spawood Iron Mine, Yorkshire. Park Pit, Yorkshire. Oakley Slate Quarries, North Wales.

Part II—Mining in Germany, France and other countries

Lead Mining at Mecherlich, Prussia. The Flushing System. Coal Mining in Silesia. Flushing System at Gute Hoffnung Lead Mine, Germany. Besse-Hütte Iron Mine, Pöhl, Germany. Coal Mines of Carmaux, France. Notes on Mining, Timbering and Lighting.

NEW YORK, FEBRUARY 13, 1909.

NO. 7.

Mining and Milling at Rawhide, Nevada

The Mines Have as yet Reached No Great Depth and Are Developed Chiefly by Leasers, but the Camp Has a Promising Future

B Y G. E. W O L C O T T *

Rawhide lies just within the northern boundary of Esmeralda county, Nev., and a little north of east from Schurz, 24 miles distant, at the head of Walker lake. Schurz is the nearest railroad station and most freight and express business is done through this town. Automobile lines run to Schurz, to Fallon, 50 miles northeast and to Mina, about the same distance to the south. The automobile fare from Schurz is \$10, and from Fallon or Mina, \$12.50 for a one-way ticket.

Rawhide has a water-works system, which is, however, rather unsatisfactory and will necessarily be replaced later by a more efficient one. Water is obtained at

system, and no electric power. A power line is soon to be extended from Yerington. Power for hoisting is of the old reliable "armstrong" type in the early stages of development, and gasoline hoists are used after sinking from 50 to 150 ft. Wood is used in the houses for cooking and heating purposes and costs \$22 per cord delivered. Lumber costs \$45 per thousand for ordinary lengths and shapes.

LOCATION

The camp lies near the base of an irregular range of hills, the most prominent landmark being Sugar Loaf mountain,

area have probably been the immediate cause.

GEOLOGY

In the absence of detailed field work a discussion of the geological features of the district must at this time be very meager. Within a radius of five miles of the camp may be found almost all gradations of igneous rock, ranging from granitic to finely felsitic in texture and from basic to extremely acid in chemical composition. The prevailing rock in which the known orebodies occur is a very acid light-colored rhyolite. Grutt and Baloon

SOURCE OF RAWHIDE WATER SUPPLY

MILL, RAWHIDE QUARTZ MILLING AND MINING COMPANY

a depth of 160 ft. in a flat, and about five miles southeast of the town. It is pumped to a wooden reservoir situated on a hill between the pumping plant and the city and then flows by gravity to the water mains. Only the business portion of the town is piped, and when lines are carried to dwelling houses they must be paid for by the owners of the houses supplied. A large part of the water is still hauled from wells near the pumping plant, where it is sold to dealers at 10c. per bbl. At the houses it is retailed at \$1 per barrel. The town has as yet no efficient lighting

about five miles to the westward. This mountain presents an interesting rock formation in the shape of columnar basalt, which forms the entire top of the mountain. Immediately east of the peak are strong evidences of an ancient volcanic crater, while farther to the east and nearer Rawhide are at least two distinct lava flows, the later one being a volcanic breccia from the inclusion of boulders from a previous flow. It is probable that this eruptive center is connected in a way with the formation of the orebodies of Rawhide, although not an immediate cause. Secondary phenomena attendant upon the gradual cooling of the affected

hills are composed almost entirely of this material, while Hooligan hill has considerable andesite.

The hills to the northwest are almost entirely rhyolite. The basalt intrusions to the westward have already been spoken of. Besides these there are various other intrusions of this same material, but of less extent, breaking through the rhyolite in several localities. Because these intrusions are entirely surrounded in places by rhyolitic material it is probable that they are later than the rhyolite; also the fact that the basaltic flows, before spoken of, lie on top of rhyolite practically proves the correctness of the assumption.

*Mining engineer, Rawhide, Nev.

ORE-BEARING AREA

A circle drawn from the main street of Rawhide and embracing Grutt, Baloon, Murray and Hooligan hills will include the main portion of the gold-producing area. Many prospects of more or less importance occur outside of this area, but these are of secondary importance so far as developed. Regent, lying about two miles to the northwest, has two shippers and presents a considerable area of much promise. Royal hill, two miles to the westward also has a producing mine. Favorable quartz veins in rhyolite also occur two miles to the northeast, but they have not as yet shipped any ore. From this it appears that the productive area from which Rawhide will draw its ores is of considerable extent.

PLACER GOLD

The ravine in which the main portion of Rawhide is situated, as well as those south and southwest of the town, have

dium. The air current is produced by a belt-driven fan connected to the gasoline engine which furnishes the power for the whole operation. The plates are given a horizontal motion by suitable mechanism. The machine illustrated was operated by a 11-h.p. engine, and is said to have effected a saving of about 90 per cent. of the gold. An installation for wet washing in the lower part of the town is now in operation. This is working from a 70-ft. shaft, the bedrock being at that depth. Water is obtained in this case by connection with the city water main. Several hand rockers are also operated in the small ravines, the water being bought by the barrel.

The gravel deposits below Rawhide are of considerable depth and would seem to offer a good field for dredging operations provided sufficient water could be obtained. So far as I know, however, there has been no systematic sampling to determine its value.

The ore has in many cases been of a very high grade; in one or two cases the material sacked contained nearly half of its weight in gold. There is not, however, as much high grade as various newspaper accounts would lead one to believe. Due allowance must always be made for exaggeration. The truth of the reports is, however, sufficient to warrant the assumption that Rawhide will contribute materially to the world's wealth within the next few years.

THE MINES

Strictly speaking, there are no large mines in Rawhide. So far as my information goes, there is not a single company owning and operating its own property, although some are planning to do so. The result is a very large number of leasing concerns operating either privately, or as stock companies, and doing business on a comparatively small scale. Many of these companies are short of funds to

DRY WASHER USED ON RAWHIDE GOLD PLACERS

KERN'S NO. 2 MINE, RAWHIDE, NEV.

furnished considerable placer gold and are still being worked to some extent. The lack of water has been a drawback in placer mining.

The dry-washing machine shown in an accompanying illustration ran with some success for a few months. This machine utilizes the principle of the jig except that the water is replaced by a rising current of air. The machine consists of a chain-bucket elevator into which the gravel is shoveled. This elevates the material to a revolving trommel, the oversize from which goes to the dump, while the undersize passes to two iron plates 7 ft. long by 1 ft. wide set at an angle to suit the conditions of operation. These plates have D-shaped openings about $\frac{1}{2}$ in. wide and $\frac{1}{2}$ in. deep, through which the rising current of air passes. Across the bottom of the plate a wire screen is attached, while a sheet-iron trough running the length of the plate serves to catch the concentrates and also to direct the air current which acts as the separating me-

THE OREBODIES

The orebodies consist essentially of quartz gangue, either massive in the vein, or in the shape of a network of quartz veinlets impregnating the country rock. Massive quartz is especially prominent in the Murray lease toward the lower end of Baloon hill, sometimes called Murray hill. So far as developed most of the veins are either vertical, or only slightly inclined, and show, as a rule, a northeast-southwest trend. The ore carries chiefly gold with subordinate silver, or with silver predominating in some cases.

In the ore channels the rock is usually very hard, due to the presence of quartz. Away from the quartz areas the material is often soft and decomposed, frequently presenting a stratified appearance. Layers of crystallized gypsum also occur in this material. A green gouge is found in places, which is supposed to have some connection with the ore deposits, but which is probably only an alteration product formed by attrition.

push development work, and the camp's progress is checked somewhat by this condition. In many cases the workmen are working for stock instead of wages, this being the only currency available. There are at present probably no less than 50 leasing companies operating in the immediate vicinity of Rawhide. Of these a large proportion are shipping or have shipped some ore, and others have low-grade ore blocked out, which is not at present available.

The deepest shaft is that of the Kern's No. 2, which is 400 ft. deep. With the exception of this shaft none is below the 300-ft. mark, and few below 200 feet.

At present only ore of comparatively high grade is available for shipment, very little material lower than \$30 being marketed, and this yielding only a small margin of profit. This fact is bound to react favorably to the owning and unfavorably to the leasing interests. In the search for high-grade ore, more or less low-grade material has been and will be developed.

which, with better treatment facilities, will be made available. The owner is thus placed in the enviable position of having his property developed without any risk to himself and of being able to undertake operating on his own account when conditions warrant.

The leaser is certainly the one who has the short end of the bargain, for it is his money that is risked, and under present conditions only high-grade ore will return him any margin. In spite of this, however, any favorably situated property will not look long for a leaser who is willing to take the risk.

Practically all of the mining is still done with hand steel, only one or two small compressors having been installed. The soft, decomposed material previously spoken of frequently admits of working with an auger drill. An accompanying illustration shows an interesting and highly efficient method of using the auger bit observed in some of the mines. It

METHOD OF USING AUGER

consists simply of a wooden lever with an iron point that can be inserted in the floor of the drift. One man applies force at *A* while another turns the bit. A 3-ft. hole can be drilled in fairly gritty rock in about five minutes. The same hole with hand steel would take about 30 minutes. Water is used in drilling down holes.

MILLING

The milling facilities of Rawhide are as yet of little economic importance, and will not be for some time. More development work must be done to ascertain with reasonable certainty the possibility of a continual ore supply before any mills of large capacity are justified. Moreover, the process of treatment best adapted to the ores should first be ascertained. At present the deepest shaft is only 400 ft., so that not enough work has been done to determine the character of ore in depth. So far as developed the ore would probably yield good results by amalgamation and cyanidation without concentration. This assumption is, however, based only on a general knowledge of the character

of the ore and not on any experimental data. Silver is present largely as cerargyrite, which yields readily to cyanide treatment, while sulphides are not abundant.

The present milling plants are of more interest from a metallurgical standpoint than because of their economic importance. There are two plants at present operating, both situated on the flat lying southeast of the town and from six to seven miles distant. The roads from the mines to the mills are all down grade and ore is hauled in wagons at a rate of \$2 per ton. The cost of transportation to the railroad is \$6.

At the first mill visited, which is known as the Watt mill, the ore goes first to a Dodge crusher, and is then elevated to a storage line from which it is fed to a single Tadmor mill. From the mill the ground product goes to a single Wilfley table making tails and concentrates. The milling plant is not very elaborate and is hardly worthy of description except as illustrating the application of a new crushing device designed to take the place of stamps. Ore is treated in lots of from 10 to 15 tons at a charge of \$10 per ton, the seller receiving the value actually recovered. About 30 to 40 lb. of quicksilver are placed in the mill for each lot of ore, and a clean-up is made before changing lots. The concentrator has so far proved of little value, for the concentrates run only from \$10 to \$12.

NEW MILLS

The Tadmor mill used at this plant is operated by an overhead eccentric bearing which gives a heavy muller a movement somewhat similar to that of a gyratory crusher. The crushing is, however, done by the weight of the muller which grinds the ore upon the lower die. By this means a continuous grinding operation is secured, the mill at no time doing ineffective work. The machine shown in the accompanying illustration has a muller weighing 8000 lb. and is operated with a power consumption of less than 3 h.p. Crushing from a 1½-in. maximum to from 40 to 60 mesh the mill is said to handle from 20 to 25 tons per 24 hours and crushing to 120 to 150 mesh about 12 tons. These are the figures as given by the mill superintendent, the ore being a fairly silicious one. The fineness of crushing is regulated by the depth of discharge and by the flow of water which carries the ground pulp to the discharge launder.

Objection has been made to this mill because the heavier particles would tend to accumulate in the mill until pulverized to a greater degree than the lighter portions. This would not be a serious drawback where cyanidation follows the crushing as the final operation, but it would be a disadvantage in concentration. This may account in a measure for the low

value of the concentrates obtained in the mill.

RAWHIDE QUARTZ MILL

The second mill, that of the Rawhide Quartz Milling and Mining Company, locally better known as Swift Water Bell's mill, is situated about two miles east of the Watt mill and is slightly more elaborate in design. A flow of 30,000 gal. of water per hour is obtained here at a depth of 40 ft. The ore is dumped directly upon a ¾-in. screen the oversize going to a 9½×12½-in. Blake crusher. The combined products are then elevated to a storage bin from which they are fed by an auto-

TADMOR MILL

matic feeding device to three Knight cannon-ball mills. The product passes to a 30-mesh screen which returns the oversize to a fourth cannon-ball mill for regrinding.

The 80-mesh product is caught in a stream of water which carries it over riffles containing mercury and then through amalgamators of peculiar design as shown in the accompanying illustration. Both the upper and lower interlocking V's are of silver-plated copper plates. The purpose is to save any fine gold which might float off by causing it to come in contact with the amalgamating surfaces. From these amalgamators the pulp passes

over five amalgamating plates, 4 ft. wide and 12 ft. long, and then to two 9-ft. Pinder concentrators. The concentrators make concentrates and middlings, which are saved, and the tailings which at present go to waste but will later be treated in a cyanide plant.

OTHER PLANTS

The cannon-ball mills used in the mill are designed to supersede stamps and are being tried for the first time in actual mill work. They have not been in operation long enough to justify any conclusions as to their probable efficiency. The machine consists first of a horizontal flat iron disk with three rings at increasing distance from the center which is the axis of rotation. Each ring carries a number of chilled-iron balls, uniform in size for each ring but diminishing in size from the inner to the outer ring. This allows of the use of balls worn down in the inner ring in the

the railroad Schurz will be the natural location of any large milling plant for abundant water is obtainable at this point.

Rawhide has been a boom camp by reason of the fact that high-grade ore was found near the surface. Just now it is passing through hard times. Bank failures and fire have materially crippled its progress as has also the prevailing financial stringency. Besides, Nevada has ceased to be the enchanting word that it was in the time of the Goldfield boom. Nevertheless, Rawhide is on the map to stay. It has, of course, its wildcats and fake promotion schemes and the town has outgrown the mines. The number of men actually employed and the amount of ore shipped do not justify a town of nearly Rawhide's population. Looking at the matter prospectively, however, I am strongly of the belief that Rawhide is destined to be a big producer.

Deep Mining at Grass Valley, California

SPECIAL CORRESPONDENCE

Activities in the Grass Valley district in Nevada county, the most productive quartz-mining section of the State, are such as to give encouragement to miners in other portions of California, where any deep mining is being carried on. The older and deeper mines of Grass Valley are the more productive and prosperous. Whatever barren zones occurred, as they do in most places, have been passed with development, and the ores on the lower levels are proving as valuable in content as those found nearer the surface 50 years or more ago. This fact is being proven in Amador county as well, more particularly in such mines as the Kennedy, where very deep exploration is being carried on. At Grass Valley the Empire, which is the oldest recorded quartz mine in the State, continues to be one of the largest gold producers in California. This vein was discovered in 1850. The company after all these years' work and after having attained a depth in its shaft of 3400 ft., is now about to install an extensive pumping system which will permit still deeper mining. In the same district the North Star Mines Company has attained a depth on the incline of its shaft of 5000 ft. without any diminution in size or value of its fissure. It is expected that this incline may eventually be carried down to 9000 feet.

Both the mines mentioned were supposed at different times to be worked out as barren zones were encountered. In this same Grass Valley district in the Idaho-Maryland the water is now all out from the 1000-level station and new timbers are being put in. Principal operations are just at present confined to the 500 and 700 levels. The ore found is of good quality and the mill is kept running upon it.

The grade of ore worked in Nevada county is higher than elsewhere in California. In 1907 there were 225,830 tons of silicious ore milled yielding an average of \$0.66 per ton. From this ore 4140 tons of sulphurets were treated yielding an average of \$58.18 per ton. The saving on the plates alone was \$7.00 per ton. At the North Star mine in that year there were 78,366 tons of ore milled, yielding an average of \$11.06 per ton at an average cost of \$5.00 per ton for current operation, and \$1.18 per ton for development, making an aggregate cost of \$6.27 and leaving a realized profit of \$5.68 per ton over all costs of operation and development. Labor strikes stopped operations two months.

Main haulage drifts should be well drained.

SECTION AND PLAN OF AMALGAMATOR

outer rings. The balls are held in place and under pressure by overhead rings so arranged that the pressure on each ring may be changed separately or together. The ore is fed in the center of the machine and escapes at the periphery, the crushing being done either wet or dry. A capacity of 30 tons per 24 hours from 1 in. to 80 mesh with a power consumption of 8 h.p. is claimed by the inventor. This is for a machine with a 26-in. outer ring and having balls $3\frac{3}{4}$, $3\frac{1}{2}$ and $3\frac{1}{4}$ in. in diameter. There are nine balls in the inner ring, 16 in the second and 24 in the outer ring.

Besides these mills there is a 10-stamp mill with cyanide amex in process of construction at Schurz, and also one designed to use Huntingtons for fine grinding and employing amalgamation only, near Rawhide. After the completion of

The temperature of the rock in the Victoria Quartz mine, Bendigo, Victoria, Australia (Donald Clark, *Aust. Min. Stand.*, Nov. 18, 1908), is 113.5 deg. F. The temperature of water issuing from the rock at this depth is 114 deg. F. Ventilation is so good that on the first working level above this depth, the 4254-ft. level, where the rock temperature is almost as high, the air temperature is only 75 deg. F., when the shade temperature at surface is 95 deg. F., and 72 deg. F. When the shade temperature is 60 deg. F., the circulating air soon makes a surface skin of cool rock in the workings so that, provided the fresh air is not saturated, the temperature in the drifts and stopes does not become excessive. On this level the air is heated about 1 deg. F. for every 100 ft. of crosscut or drift that it passes through.

Montana Corporations

SPECIAL CORRESPONDENCE

By the laws of Montana all corporations organized within the State, and having a capital stock, are required, within 20 days from the last day of December of each year, to file in the office of the clerk and recorder of the county in which the principal business of the corporation is carried on, an annual report. If such report be not filed, each director of the company failing to make the report becomes individually liable for all the debts of the corporation. The report is required to state the amount of capital stock of the corporation actually paid in, and the amount of corporate liabilities, and must be sworn to by the president or vice-president of the company. The following are the statements filed in the county clerk's office of Silver Bow county in Butte:

Monongahela River Consolidated Coal and Coke Company

This company, known as the river combine, owns a number of coal mines and a large area of coal land in the Pittsburg district. It also owns and works coal lands in Kentucky. Most of its mines contribute to the trade on the Ohio, though it sells much coal in Pittsburg and vicinity. The last annual report covers the year ending Oct. 31, 1908. It shows that the company has outstanding \$20,000,000 common and \$10,000,000 preferred stock; \$8,211,000 bonds; \$1,440,000 certificates of indebtedness; \$286,000 car trust notes and \$172,834 mortgages. The debt was reduced \$575,226 during the year by sinking fund and other payments.

The coal lands originally held by the company included 35,194 acres, on Oct. 1, 1899. Since then 4830 acres have been

The income statement for the year is as follows:

Net earnings over working expenses.....	\$1,888,330
Depreciation of mine equipment.....	\$ 207,630
Depreciation of river craft.....	330,364
Depreciation of coal lands.....	226,015
Total.....	\$ 824,009
Net balance.....	\$1,064,321
Interest charges.....	\$ 688,355
Dividend No. 14, preferred.....	330,000
Total payments.....	\$ 938,355
Balance.....	\$ 125,966

Adding \$1,975,742 brought forward from the previous year made a total surplus of \$2,101,708 at the close of the year.

The report says: "An insurance fund of \$200,000 has been accumulated, which with the monthly premiums accruing, has been deemed sufficient by the board of directors to meet all future fire and marine losses.

"Considering the general business depression, which has extended over the past year, and the low-water period over seven months, from June 1, 1908, to Jan. 7, 1909, during which time no coal was shipped, our production and sales have been fairly well maintained. The temporary suspension of mining operations during the month of April resulted in a loss of production of about 400,000 tons. While river conditions during the months of April and May were very favorable for boating, yet we did not have any coal to ship because of the suspension, which rendered our steamboats idle during that time and resulted in a shortage of coal in our Southern markets, which made it necessary to secure supplies by rail from West Virginia, Kentucky, Tennessee and Alabama, to take care of our contracts and trade; this alone diminished the sales of our own coal to the extent of about 400,000 tons.

"The physical condition of our property has not only been fully maintained but has, in the main, been materially improved. Our coal mines are in better condition now than at any time heretofore. As old mines are exhausted, new mines are developed according to modern methods, with a view to increased production at a minimum cost. The physical condition of our river equipment is being fully maintained. As old barges are disposed of, new barges are provided to take their place. At New Orleans, we have, during the past two years, installed modern coal-handling machinery for transferring coal from the river barge to the bunkers of the steamships, at a cost of about \$100,000, which has resulted in a material saving over the old method of hand labor and quicker dispatch in delivering coal to the steamships, which is a great advantage to our customers."

In his work, "The Iron Ore Deposits of New South Wales," J. B. Jaquet estimates the minimum quantity of ore to be 59,317,000 tons.

While fighting an underground fire at the Testasecca mine, Sicily, the men, who used fire-fighting helmets, at first were able to work continuously 2 or 3 hours at a time without great fatigue, but (F. C. Chrambach, *Bull. No. 50, I. M. and M.*) after a time they could not do even easy work for more than 3/4 hour at a time. The atmosphere was composed of nitrogen, sulphur dioxide and carbon dioxide without a trace of free oxygen. The fatigue was evidently due to the absorption by the blood of carbon dioxide through the pores of the skin.

bought, and 7881 acres mined out and sold, leaving 32,143 acres owned; of which 29,630 acres are in Pennsylvania, 2513 acres in Kentucky.

The coal statement for the year is as follows:

	1907.	1908.	Change.
Pittsburg district.....	7,321,961	5,985,486	D. 1,336,475
Kentucky.....	132,196	110,624	D. 21,572
Total mined.....	7,454,157	6,096,110	D. 1,358,047
Coal sold.....	8,339,114	6,944,307	D. 2,294,807

The decrease last year in coal mined was 18.2 per cent.; in coal sold, 27.5 per cent.

Computing Tonnage from Volume of Ore Removed

By S. L. LEFEVRE* and GUY C. STOLTZ†

The magnetic ore deposits on the eastern slope of the Adirondacks at Mineville, N. Y., are worked by the Port Henry Ore Company and Witherbee, Sherman & Co. The largest deposit now being mined is worked in the "21" mine belonging to the Port Henry company and the Joker-Bonanza mine belonging to Witherbee, Sherman & Co. The property line between the two companies crosses this deposit diagonally making an angle of about 30 deg. with the axis of the anticlinal fold in which the ore occurs. The companies work together harmoniously, each when it becomes advisable to do so mining ore on the property of the other.

The volume of ore in cubic feet mined by either company across the line is computed from surveys of the sides, floor, faces and roof of the stope; the tonnage is determined by dividing this total by the number of cubic feet to the ton.

To illustrate the method followed to determine the tonnage of ore extracted in any trespass, the workings taken are two levels, one 417 ft., the other 472 ft. above Lake Champlain, which have been connected by several raises. The accompanying plan shows the extent of workings across the property line and the position of a few of the points taken from a regular survey giving the elevations of the roof, floor and sidewall of the stope, while the sections accompanying the plan will more clearly show the relations of the two levels.

To make the trespass survey a transit station of known latitude and departure is accurately established at some point, preferably near the central part of the trespassed area. From this set-up numerous side-shots are taken, azimuth, vertical angle and distance being noted in each case. Usually the floor points in the stope are taken first, then points which will determine the slope of the stope and the side walls, finally floor and roof points in the headings. It is possible by using a ladder and a tamping stick, to which is tied a light and the tape, to get all roof and other points that may be essential in determining the volume. In case all workings are not to be seen from one station, perhaps because of a pillar or a bow in the roof or side wall, then temporary stations are located for the transit, from which stations the necessary side-shots are taken.

Obviously to reduce the error in computing volume to a minimum, points should be taken very close together, but in a large area with fairly regular sides and roof probably 5 ft. is close enough to

gether for these sections. A sufficient number of points should be taken so that from the side-shots a wooden model could be constructed, which if put together in the workings would snugly fill the cavity.

PLOTTING

After the horizontal distance and elevation of the different points has been computed, the points are plotted from the main station within the trespass area by means of a protractor. Plotting is done on coordinate tracing paper, ruled to divisions to the inch, on a scale of one inch to ten feet. The number, elevation and location of each side-shot is noted on the plan. When break-throughs make it necessary to determine the volume of two levels together, to avoid confusion the points on the levels are recorded on the plan in inks of different color.

After inspecting the map and studying the character of the ground the location of the sections are so selected that the average area of each two adjacent multiplied by the distance between will give as accurately as possible the volume of ground between the sections. After the sections are located the elevation of the surveyed points that are included in each section together with the elevations of interpolated points are plotted; the horizontal distance of these points from the property line on each section is determined by scaling from the plan. The height between floor and roof is then scaled or determined by difference of elevation at as many points as necessary to get the area of each section accurately.

After the area of each section and the horizontal distance between sections has been tabulated, the volume in cubic feet between all of the sections is determined by summing the area of each of the two adjacent sections, dividing by two and multiplying by the distance between sections.

Finally the tonnage is determined from the total volume in cubic feet by dividing by 7.85 cu.ft. for this factor has been agreed upon by both companies after a series of specific gravity tests had been made upon lumps of ore of average analysis.

Silver-Lead Smelting at East Helena, Mont.

SPECIAL CORRESPONDENCE

The East Helena smelter has three of its four furnaces running, all on a fairly rich lead charge; i.e., the percentage of lead is about 25, which is considerably above the average. The smelter is now treating a larger quantity than usual of rich *Cœur d'Alene* concentrates. The whole battery of 16 long roasters and a complete equipment of Godfrey furnaces and H. H. pots, 12 in number, is roasting these ores and the percentage of lead on

the roaster charge is as high as 40. Consequently the pots are delivering a much better product now. The company intends installing several new Godfrey furnaces and accompanying pots; the management prefers the Godfrey and H. H. pot combination to any of the improved roasting machines.

It will be remembered that for about three years, the baghouse was not used at this works. Since it was put in commission again, about 18 months ago, the company seems to have had greater success in the life of the bags. Formerly the bags, 30 ft. by 18 in., made of cotton duck, lasted eight or nine months; now their average life is 18 months. The cost of a bag at Helena is \$1.25@1.50. Tacoma's bags, of much lighter duck, cost about 80c., while Selby uses a more expensive woolen bag, for which a longer life is claimed. The company has experimented with a view to lengthening the lives by dipping them in linseed oil, and wringing them dry; also saturating with the theater-curtain kind of fireproof paint, but without favorable result.

Pertusola was the first smelter, I believe, to use an automatic shaking and collecting device. A shaking device has also been introduced at the United States Metals smelter, near Salt Lake City. Pertusola also uses a patent asbestos-thread bag.

East Helena has found that by adding a large percentage, about 25 lb. believe, of lime to the charge in the Godfrey furnace the output is increased, and the resulting roast in the pots is much sweeter.

Everett generally treats the baghouse dust, which runs about 40 per cent. arsenic, and 40 per cent. lead. On account of the present prevailing low price of arsenic, Helena has been compelled to treat the dust itself. This is first burned on the floor of the baghouse, where it sinters and cokes and is freed of some of its arsenic. On adding this burnt dust to the charge, the furnace distilled arsenic heavily, and the bullion resulting contained 0.5 per cent. arsenic. Very little speiss was formed. The use of more than small quantities of raw concentrates on a blast-furnace charge is deprecated, it being claimed that matte-fall is high, and higher in lead when considerable copper is on the charge (decreased reduction), with correspondingly fouler slags. The only explanation offered for the prolonged life of the bags is that for some reason the gases are cooler now than in former years.

A stamp duty of 15 tons per 24 hours is obtained at the Giant mine, Hartley district, Rhodesia (R. C. H. Cooke, *Journ., Met., Chem. and Min. Soc. of South Africa*, Nov., 1908), where a soft ore is crushed through screens having $\frac{3}{4}$ and $\frac{1}{2}$ -inch openings, and subsequently tube-milled.

The Rotary Blower in Smelting Works

Principles of Producing Blast by Means of Rotating Impellers, Simplicity and Efficiency of Apparatus and Essentials of Successful Operation

BY GEORGE C. HICKS, JR.*

The rotary blower has won a permanent place for itself in smelting work, both because of its adaptability to the work to be performed and by reason of its all-round efficiency. While the rotary type of blower is fairly well understood, there are a number of points about its operation and management which are not as familiar as they might be.

The principle of operation of the rotary blower is the rotation of two moving parts in definite relation to each other, these two parts being composed of curves

therefore, drawn in and discharged twice a revolution for each impeller, making the displacement of the blower equal to four times this amount.

The air is drawn in under the conditions prevailing at the suction and is maintained at this same pressure until the upper edge of the case is reached. The impeller tip then passes the edge of the case and the air between the case and the impellers is immediately raised to the discharge pressure. This sudden rise makes a certain fluctuation in the discharge of the blower

charge valves were opened at the end of the suction stroke and the piston discharged the total amount of air in the cylinder against the discharge pressure, instead of compressing it adiabatically or isothermally until the discharge pressure had been reached and the discharge valve opened.

This difference between the square card and the adiabatic card is often made use of in comparing the reciprocating compressor with the rotary blower to the disadvantage of the latter. Since the amount

ROOTS BLOWERS, MOTOR AND BELT DRIVEN

of such form that uniform clearance is constantly maintained between the outlines of the respective impellers, the point of contact being either on or contingent to a line joining the centers of the two rotating shafts. The clearance contact at this point prevents the return of the air which has been drawn in by the rotation of the lobe in the case, thus inclosing the air lying between the outline of the two lobes and the case. This volume of air is,

by reducing the pressure at the entrance to the discharge pipe, so that the discharge pressure at that point represents a wave line. It also has a tendency to reduce the average pressure against which the blower operates; and while the amount is small, it reduces the horsepower from that given by the square card, the theoretical card for the rotary blower, because the entire discharge of the blower is made against the discharge pressure. The conditions are the same as those which would prevail if in a reciprocating machine the dis-

of this difference is small at low pressures, and the slip of both the suction and the discharge valves of the reciprocating blower in addition to the excess vacuum and discharge pressures required to open them is considerable, the amount lost in the rotary blower is more than offset until the pressures begin to reach six or eight pounds.

POWER AND PRESSURE

There is one point that should be thoroughly understood in regard to the rotary

*Engineer, P. H. and F. M. Roots Company, Cincinnati, Ind.

blower and that is, that it is a positive displacement machine, that the amount of air and the horsepower required are proportional to the speed and pressure under which the machine operates, the increase in horsepower being in direct proportion to the increase in pressure and also, directly in proportion to the increase in speed, or, which is the same thing, the amount of air delivered.

The formula for calculating the horsepower of rotary blowers is $\text{h.p.} = 0.00436 \times \text{displacement per minute} \times \text{pressure}$. This is the formula for the square card; while the actual power necessary is less than this, the results given by this formula are close enough for all practical purposes; it is the formula generally used for

pretty nearly settled down to two types: the double-gearred blower and the machine with single gears, i.e., gears at one end only and double outboard bearing driven from a steam engine by direct connection or from a motor by means of a belt, a single outboard bearing outside of the fly-wheel supporting the weight and helping to take care of the belt pull. The double-gearred type can be used only with motor drives and consists of a machine geared at each end, with single outboard bearing on opposite shafts, the blower being driven by two motors belted to two band wheels, each carried by the bearing of the blower itself and a single outboard bearing. This arrangement has some good features; it relieves part of the load from

other, as in the case of the electrical drive. It might possibly be done with an engine, but it would necessitate excessively heavy flywheels, in order to prevent back-lash in the belting.

The double-outboard bearing arrangement has the advantage of furnishing a support on each side of the gear, and makes it comparatively easy to keep the line contact of the gear face touching throughout the entire width of the gear. This keeps the wear uniform and prolongs the life of the tooth.

SPEED AND CAPACITY

The speeds of rotary blowers are really determined by the safe, practical and economical working speed of gears. There

ROOT BLOWER DIRECT-DRIVEN BY CORLISS ENGINE, SHOWING FLEXIBLE COUPLING

obtaining the power necessary to drive a blower, or, rather, to move the necessary air. An additional amount must, of course, be allowed for friction.

The simplicity of the rotary machine is in its favor; it has only two moving parts, and while these parts are made up of several pieces, they form, as a whole, only two rotating units; thus, the impeller, shaft and gear comprise one of the two units. This simplicity and the size and strength of these two units is one of the great points that make the rotary blower so successful and so well able to withstand hard and continuous usage.

SINGLE OR DOUBLE GEAR

The blower used for smelting work has

being transmitted through the gears, and in the case of motors that respond quickly and divide up the load so as to keep the tension on both belts practically equal, the arrangement is successful; but the experience has not been satisfactory where the same arrangement is attempted with belts from a line shaft, the trouble being the impossibility of maintaining the two belts at exactly the same tension. If it is desirable, for some special reason, under these conditions, to drive from both ends, it is better to drive to the same shaft. This also applies to the application of the cross-compound engine to the blower, i.e., the high- and low-pressure sides of the engine should both be applied to the same shafts, not one to one shaft and one to the

is no reason why impellers properly balanced should not rotate at a good deal higher speed than rotary blowers are usually run; but it is a well known fact that the limiting speed of gears occurs at a certain point in the neighborhood of 1200 lineal ft. per min., and that above this speed, even the most carefully cut gears begin to pound and hammer, the hammering eventually causing crystallization and the failure of one or more teeth in the gear, bringing on general disaster to the whole machine. It is, therefore, wise to keep the speed, of large machines especially, within reasonable limits. A few hundred dollars extra expended on machines of large size is well invested, as the interest on the extra amount will be much

less than the depreciation and repairs on blowers not suited to the conditions.

In picking out the proper blower for work under a given pressure, it is always well to consider the relative length in proportion to the gear diameters; the customary method of considering the length of the blower, is to refer to it as so many gear diameters in length, or simply using the words "two gear lengths" or "three gear lengths," for the length of the case. Stated in another way, the pressure on the gear teeth should be practically a constant quantity, no matter what the length of the machine may be. For instance, if the machine is of a certain length for 2 lb. pressure, and the gears are proportioned for that load, if the same amount of air is needed at a higher pressure, it should be obtained by purchasing a blower having a larger gear diameter and a shorter case.

The face of the gears chosen by the different blower manufacturers is usually about a maximum width for that size gear. The shaft strains are also proportioned for what is called a full length machine

RELATIVE POSITION OF IMPELLERS

and a certain pressure. In order to keep the main parts of the design the same, making changes in length only, it will readily be seen that the most practical and satisfactory way is to shorten the machine as the pressure increases. This tends to uniformity of manufacture and makes the duplication of parts much more simple than with any other system. The short machines are naturally easier to keep in alinement and are favorable to shop production in every way, being easier to machine, better to handle and giving increased stiffness in the machine as a whole. Two pounds is considered about the limit for a machine having a length equal to three gear diameters; above that pressure, the length should be made proportional to the pressure.

ADJUSTMENT AND ALINEMENT

The important point in all machines of the rotary type is to maintain the centers as close to their original and correct setting as possible. The whole principle of the successful operation of the blower depends upon the continuance of the center of the shaft lines at the one definite point where it was originally set. The rolling

together of the curves is sufficient explanation for the importance of this point, and also the fact that the impeller must revolve in the case with a very small clearance. It is not a difficult matter to keep these adjustments at the proper point, for the bearings are large and the pressure per square inch seldom exceeds 100 lb. The adjustments are in such form that the shaft may be moved in any direction, and with a little care and attention, it should be no trouble to keep a machine in perfect adjustment. The life of the gears is thus also increased; for if the shaft is allowed to wear low on one end, or to become misplaced, the line of contact on the gear face immediately changes and the work is thrown on one end of the teeth until the wear has again brought the gear down to contact along the full width of the gear face.

It has been the custom to build large smelting blowers with excessively small clearances; while perhaps the critical stages of competition might have justified this, it is not to the best interests of either the manufacturer or the consumer. A machine built too close is very hard to

ARRANGEMENT FOR DIRECT-DRIVE BY CORLISS ENGINE

keep in proper adjustment, and the chances are that at the end of six months or a year it will not be in as good condition, nor will it have given as good average efficiency as a machine originally built more open. It is not necessary to go to extremes either way. The sacrifice of 1 or 2 per cent. in volumetric efficiency affords a machine with clearances within the easy limits of planer work, makes the assembling easier, allows more latitude for wear, and at the same time makes the adjustment an easy matter, instead of a continual burden on the plant operators.

EFFICIENCY

The question of efficiency is pretty well understood, but there are a few fundamental principles governing it which it will be well to explain. As the openings between the impellers themselves, between the heads or ends and the impellers, and between the case and the impellers have practically a constant area, it necessarily follows that the leak per unit of time, under a given pressure, is also a constant quantity. It is, therefore, possible by closing the discharge, to operate that machine at just such speed as will maintain on the

discharge side a test pressure. The displacement of the machine multiplied by the number of revolutions will then give the slip. This quantity is practically constant per unit of time and represents the volumetric efficiency of the blower. The increase of speed is a modifying element in this case, however, as it can readily be seen that the moving of the impeller tip past the case increases the frictional resistance of the air passage. In other words, as the friction is a function of the velocity, and the velocity is a question of relative movement, the higher the speed of the blower the greater, necessarily, will be the relative velocity of the air through the openings between the impeller and the case.

This method of testing, however, gives a good indication of the condition of a machine, and can always be assumed to give 2 or 3 per cent. more than the actual slip, at the normal speed of the machine. There are, of course, several other ways of testing, notably by the Pitot tube and the flow of air through a standard orifice. The latter method is a little uncertain, owing to the fact that measuring and cali-

brating an orifice for such large quantities of air as those handled by rotary blowers, is a very difficult undertaking and has not yet been successfully done. A number of tests have been made with the Pitot tube method, and some good work has been done in that direction by various engineers throughout the country.

One very clever way of testing the blower with closed discharge consists in taking an indicator diagram from both the suction and discharge sides. In the case in which this method was employed the machine handled gas, and both the suction and the discharge valves were closed. The card, therefore, by indicating the distance above and below the atmospheric line shows clearly the leak through the blower at different points of the revolution; the point where the engine passed over center, slowing down, due to the lack of flywheel capacity, showed very clearly on the card both lines above and below the atmospheric line being nearest at that point.

Rotary blowers can be built for 6 or 7 per cent. slip, at 3 lb. pressure, but it has been my experience that a machine allowing for 8 to 10 per cent. is better for all

purposes, and that the slight loss in efficiency is more than made up in the saving in expense of extra care and attendance.

FRICTION AND ALIGNMENT

The question of friction in rotary blowers is not a serious one, for the percentage of total load consumed in this manner for pressures of $1\frac{1}{2}$ to 3 lb. varies from 6 to 8 per cent., according to the load, i.e., the lowest friction will occur at the highest load.

As the rotary blower is operated usually at a speed not far from that of the ordinary Corliss engine, this engine and blower naturally form a very good combination, and blowers are used with either the simple or tandem-compound engine, the tandem-compound condensing combination being very efficient and extremely simple.

It has become the custom of late years to make the connection between the engine and the blower with some sort of a flexible coupling, which takes up any slight movement of the engine shaft, misalignment or end thrust without transmitting any effect to the blower beyond a purely rotative one. This coupling also allows the blower to be adjusted freely without

FLEXIBLE COUPLING FOR BLOWER

regard to the engine; some types can be disconnected as quickly as the ordinary belted coupling.

Blowers for smelting works are almost all of the horizontal type, i.e., the two shafts lie in the same horizontal plane, with the discharge either at the top or the bottom. Unless the pressure is excessive, there is no objection to bottom discharge, for the weight of the shafts, impellers and gears is sufficient to keep any undue pressure off the caps. The position of the discharge is, however, rather a question of convenience, although it would seem that the lightening up of the pressure on the bearings in the down-discharge type would tend to increase the life of the machine.

RELIEF VALVES AND FOUNDATIONS

Two things which should always be specified in purchasing a rotary blower are that the machine be equipped with an automatic relief valve set between the blast gate and the blower itself, and also that this relief valve be capable of being operated by hand, or else that another valve to be operated by hand be placed on the machine. The office of

the latter is to relieve the pressure while starting a machine, enabling the operator to get the blower practically to speed before opening the blast gate and to close the blast gate before closing the machine down, the automatic relief valve being necessary in case of any sudden stoppage, such as the dropping of the gate valve, or the closing off of an unusual number of furnaces without proper warning to the machine room.

The question of foundations is one that should never be overlooked; foundations should be of such a character that the machine will have no strains induced by settling of the foundation. No rotary blower will operate successfully when the case is sprung or twisted, no matter how slightly, for the length and weight of the machine are such that its mass is bound to follow the settling of the foundation. This is, of course, true not only of rotary blowers, but also of any type of machinery; the better the foundations the better will be the satisfaction and the lower the cost of repairs and wear of the different parts.

It is also important that the suction be properly screened so that nothing of a solid nature can reach the working parts of the machine. Machines have at various times been badly injured by carelessness in this respect, and it is often very hard, under such circumstances to find the real cause of the damage; it is a case where "an ounce of prevention is worth a pound of cure."

This remark also applies to the treatment of gear housings and to carelessness in leaving a wrench, nut, or bolt lying between the teeth when the gear cover is off and some work is being done on the machine; this is sure to result in disaster when the machine is started. The curve of the gears to the point of contact makes a very convenient place in which to lay wrenches, nuts, etc., something which should be positively prohibited in the management of the plant. Workmen should not be allowed to use even temporarily the gears as a resting place for tools, for, sooner or later, someone's forgetfulness will be sure to cause serious trouble.

St. John del Rey

SPECIAL CORRESPONDENCE

The latest report of this English company, owning and working the Morro Velho mine in Brazil, covers the first six months of the company's financial year, from March to August, inclusive: It states that 89,200 tons of ordinary ore were crushed, giving a yield of £158,842 or 39.6s. per ton. In addition £4339 were realized from low-grade mineral. The yield of gold shows a decrease of 2s. 7d. per ton compared with the corresponding period in 1907, and there was a falling off in the profit of £7218. The duties and charges on bullion come to close on

2s. per ton of ordinary mineral crushed, the ton being 2240 lb. The working costs in Brazil amounted to 29s. 8d., the developments in the mine to 10½d., and London general expenses to 7¾d., making a total cost, including bullion charges, of 33s. 1½d. per ton milled.

A dividend of 6d. per share on the ordinary shares has been paid, an amount which the chairman thought would be increased to 8d. per share at the close of the next six months' working, as there would be less necessity of devoting so much of the profits to capital expenditures.

In the past large sums have been spent out of profits in erecting and equipping power plant. Advantage has been taken of the water power which exists within reach of the mines, and as much as £240,000 has been spent in the last seven or eight years in hydroelectric power plant. The total electrical power is close on 2000 h.p., distributed as follows: Mine, 990 h.p.; reduction works, 873 h.p.; mechanical and lighting departments, 96 horsepower.

As regards the mine the manager reports that all points were looking well. The ore reserves are 1,000,000 tons, but the grade was below what had been obtained previously.

In addressing the shareholders the chairman, Frederick Tendron, not content with giving his audience a lucid account of the financial position and prospects of the mine, discussed at some length that thorny subject, the genesis of ore deposits, a subject which most mining engineers are cautious about tackling. After studying the works of de Lannay and others, Mr. Tendron was quite satisfied that the Morro Velho vein has all the characteristics of a "primary" lode, which is the best sort of lode to have, as it goes down as far as one can follow it, and has a tendency to increase in value rather than diminish with depth. These favorable conclusions will, no doubt, be indorsed by the shareholders, who, whether they grasp what a primary lode is or not, will, at all events, feel confident that their affairs are being looked after by a chairman who has heart and soul in the business, and who, when he has found out exactly how the gold got there, will know all that is worth knowing about the St. John del Rey.

West African Gold

Gold production from West Africa—including the Gold Coast and Ashanti—in December was 24,624 oz. bullion, being 187 oz. more than in November, and 693 oz. more than in December, 1907. For the year ended Dec. 31 the total was 293,218 oz. bullion in 1907, and 297,366 oz. in 1908; an increase of 4148 oz. The bullion reported in 1908 was equal to \$5,765,622, or 279,320 oz. fine gold.

New York's Open-Air Stock Market

How Mining Shares Are Bought and Sold on the Pavement in Broad Street and How the Brokers Manage Affairs without an Organization

BY WILLIAM T. ROYCE

According to an estimate based upon a recent average day's sales, fully 95 per cent. of the shares bought and sold in the open-air stock market in Broad street, New York, known as the "Curb," are shares of mining stock. Nearly all the really great mines of Butte, Goldfield, Cobalt and other famous camps of this country and Mexico are represented, especially those huge enterprises which are too heavy for individual exploitation and are not sufficiently long established to have found a place on the Stock Exchange. At present the stocks of 70 mining companies are quoted daily, the transactions varying from 100,000 to 250,000 shares per day, and the shares of 174 mining companies are dealt in with different degrees of activity. It cannot be said, therefore, that the Curb does not play an important rôle in the mining industry.

Contrary to a belief common among practical miners the Curb market performs an actual service for mining. The activities of the men within the roped inclosure are not all devoted to gambling with the fruits of other's skill and enterprise, nor is "pulling off" schemes to fleece the innocent their chief occupation. These are merely diversions which are growing more infrequent as the Curb increases in importance.

Stocks are put upon the Curb to effect distribution among the public; also to create a market for the advantage of the investor. It is an important element in the success of the flotation of a new company by subscription, if the subscribers know that there is going to be a market for the stock.

The Curb has at times had a bad name. It has been the scene of many picturesque swindling operations; for it is no easy matter to keep this free-for-all out-door market clean. The sight of two or three hundred men busily buying and selling stock without regulations or restrictions of any kind is wonderfully attractive to the gambler and the man who lives by his wits. Restrictions imply organization, and the big Stock Exchange on the west side of the street will not permit any formal organization among the open-air brokers. But with the increase of business, especially since the invasion of Cobalt, Goldfield and other camps productive of great volumes of good stocks, the morals of the Curb have improved. Gradually a sort of informal organization, based upon honor and tacit agreement has developed; and it is becoming more and more difficult for the blackleg to gain admittance.

A few days ago an important new regulation was posted on the little bulletin board, which hangs upon a lamp-post, apparently belonging to nobody in particular but recognized by the Curb brokers as

cording to the latest report, the assets and liabilities of the company and the names of its officers and directors. This blank with its inserted data is to be posted on the bulletin board for public inspection for

LOOKING UP BROAD STREET, NEW YORK, CURB BROKERS IN THE FOREGROUND, STOCK EXCHANGE ON THE LEFT
(Copyright, 1908, by Underwood & Underwood, New York)

their own. In effect it announced that the Curb is no longer a free market, at least not free for all stocks. Stocks which can not bear public scrutiny will hereafter be compelled to go elsewhere. The new rule requires all brokers who have new stock to offer to fill out a blank, giving the location of the property, its productivity ac-

five days before the stock can be offered in the street

MACHINERY OF THE CURB MARKET

The Curb deals in stocks not sold on the Stock Exchange. Mining companies do not more generally list themselves on the New York Stock Exchange because

the prices of the shares are generally low and the uniform commission of \$12.50 for 100 shares required by the rules of the New York Stock Exchange is a damper on trading. On the New York Curb and the Boston Stock Exchange low-priced stocks do not have to pay so large a commission.

To the casual visitor in Broad street nothing can be more confusing and apparently purposeless than the antics of the gesticulating, shouting, seething mob in the middle of the asphalt pavement. As a matter of fact, nothing is more orderly and free from useless fuss than the curb market. Orders are received, executed and returned with surprising celerity, and mistakes are as rare as in any well arranged business house.

Not all of the Curb's machinery is visible in the street. The elaborate system of communication, which renders the brokers in the street accessible from the innumerable brokerage offices in New York and other cities, is hidden behind the windows of the buildings overlooking the center of operations in the street. The fronts of these buildings are cut up into small offices, the requirements of each being a shelf for a telephone and a telegraph instrument and a good window. The operator in the street is in constant communication by an elaborate and interesting system of signals with an assistant at the window, and the wires carry orders and messages to and from the brokerage office around the corner, miles uptown, in Boston or wherever it may happen to be.

Suppose a visitor from Butte, Mont., arrives at the Waldorf-Astoria by a morning train. In looking over his morning paper he finds a change in Cumberland-Ely quotations, and he decides to buy 100 shares of the stock. Without laying down his paper he may step into a stock-broker's office in the same building and complete the transaction in scarcely less time than it takes to light a cigar. The broker, telephone in hand, inquires the number of shares and the price. When the customer finishes speaking the attendant at the window overlooking Broad street is already in possession of the facts. With a few passes of his hands he communicates the figures to the house's representative in the street. The man in the street moves perhaps three paces to a group of which he knows Cumberland-Ely is the center, shouts his figures to the broker who happens to have the stock for sale, receives a nod or a tap on the wrist in acknowledgement, waves his hand to his particular window, and the broker in the hotel informs his patron that the stock is his. It is possible to buy or sell stock on the New York Curb with almost equal facility from innumerable other points in New York as well as in Boston and Philadelphia.

There are as many systems of signaling as there are brokerage houses represented on the Curb. Most of the signs employed are modification of the ordinary deaf-

and-dumb alphabet. Brokers vary their signals to suit their own convenience, secrecy being desirable and often necessary especially in communications concerning the rise or fall of prices.

Men used to busy scenes about mines and smelters will invariably wonder at the continual bustle and scurry within the ropes on Broad street. To them hurry and excitement suggest lack of organization and low efficiency. Their first inquiry naturally is, "Why all this excitement? Is something unusual about to happen?" The jostling and shouting is merely a manifestation of the universal eagerness to get things done at once. Speed in executing orders is all important, for the slightest fluctuation in the price of the stock affects the interests of the customer. A rise or fall of an eighth of a cent may alter his plans completely, and on the Curb quotations change and change again in the twinkling of an eye.

Brokers familiar with the market know at once where to go to find the center of activity for any given stock. Each of the more important stocks has a spot of its own, usually marked by a group of busy operators, where its shares are sold. These centers appear day after day upon practically the same square yard of asphalt, by common consent of the brokers. The nucleus of each center of activity is usually some individual broker who specializes in that particular stock. This also is arranged without rule or regulation. The operator merely selects the stock in which he wishes to specialize, and if he knows his business, he soon has the activity in that line centered about him.

Occasionally, when any given stock is unusually active, it will have two or more centers all attracting the operators at the same time. During the excitement in Yukon-Gold, two principal groups both interested in the same stock separated, one moving north toward Wall street while the other wriggling mob whirled and jostled about a point a block lower down. An interesting story is told of a quick-witted youngster who cleaned up a thousand dollars in a few seconds on that day. He had no money but he knew the game. From the excited arms, hands and fingers waving above the heads of the crowds he learned that the quotations in the two groups differed by one or more points. Like a flash he disappeared into one crowd, bought a block of stock, disentangled himself and plunged into the other mob and sold the same stock. This is, of course, an exceptional case. Few operators speculative on their own account; they are mostly employees of large firms at a fixed salary.

WASH SALES

Publicity is as the breath of life to the Curb as it is to all stock markets. It is the stock that is quoted in the newspapers and the rising and falling prices of which are as familiar as the landmarks along

Wall street to the brokers, that are dealt in from day to day. A stock must become known before it can find a market. A broker may, if he will, appear within the roped inclosure and shout, "Is there any market here for —?" naming an unknown stock, but he will receive no response. Merely advertising in the Lawsonian way is not sufficient to create a demand on the Curb. The brokers must have quotations before they can begin.

When a stock is listed on the Stock Exchange it already has a certain standing and its backers have complied with certain regulations which bring it to the attention of the brokers. But on the Curb stocks sometimes appear without accredited backers and without a market. To induce the brokers and the public to take any notice of these unknown shares requires some strategy and more or less cash.

In order to secure for a new stock published quotations and a market, fictitious sales or "matched" sales are arranged, one broker being given an order to buy a certain number of shares and another to sell an equal number. These brokers meet on the Curb, and buying begins, as all the world may see and hear. The brokers may be entirely innocent of the trick that is being perpetrated upon their brother operators, the newspapers and the public. They receive their regular commission and are usually unaware of any part they may have played in launching a new enterprise.

Orders of this kind skilfully distributed among a number of brokers soon brings a stock prominently before the market. Of course, someone pays the freight in the form of brokers' commissions, but that is the price that the backers are willing to pay to get the public interested in their enterprise.

When a stock is fairly afloat it still requires considerable nursing in the early stages to keep it at the desired level. Its backers must be prepared to keep the public interested and to buy in shares when the market begins to lose interest and to allow the price to sag, success depending largely upon the skill and the financial strength of the promoters. All these matters are based upon personal honor and gentlemen's agreements, and the interesting stories of treachery are repeated so often as to indicate that occurrences of that sort are rare. Many picturesque tales are told about the Yukon-Gold excitement of last March. One which has gained wide currency ascribes the sudden decline of the shares from 8 to less than 5, to the treachery of one of the promoters. This man could not resist the temptation to unload some of his own holdings when he saw the price climb. While his friends were buying in block after block of the stock to hold up the market, he quietly dumped 50,000 shares into the hopper, with the result that the market was swamped.

It is not to be understood that "wash" or "matched" sales are confined to the Curb or to the introduction of new stock into the market. Balancing orders so as to create an impression of great activity is resorted to for a variety of purposes, for the manipulation of pooled stock and to cause a boom in neglected shares. It is one of the favorite tricks of the powerful operators on the Stock Exchange, and is there carried on on a grand scale in spite of the law which places a tax of \$2 per 100 shares upon all transfers. This tax in addition to the commissions paid a score or more of brokers renders these spectacular campaigns extremely expensive.

CURB BROKERS

Theoretically anybody can step off the sidewalk in Broad street and begin buying and selling stock on the Curb, but if a stranger were to try it, he would most likely have reason to regret his experience. The open-air market is supposedly free for all, but as a matter of fact its privileges are hedged about by a lot of unwritten regulations which are about as binding as the laws of the Medes and Persians. The 150 to 300 brokers who meet on the pavement from day to day have their own methods of dealing with strangers and with one another. Hazing is a recognized means of enforcing the unwritten law of the Curb.

When a new operator attempts to join the group of traders, he is usually already well informed in regard to the rules of the game. The ranks are recruited chiefly from the army of telephone boys and assistants at the windows along the street. The curb-broker-to-be secures the service of a friend, well known in the street, to introduce him to the other operators. After the novice has been introduced and has satisfied the brokers that his word in a transaction is good, he must submit to a course of hazing. What he is compelled to suffer depends upon the mood and the ingenuity of the mob. After he fancies himself a full-fledged broker he will probably be induced to fill his order book with fictitious sales of stock bearing imaginary names.

The broker on the Curb is intensely alert. All his faculties and all his training are directed toward one aim, to develop speed and accuracy in executing orders. The successful broker must not only be familiar with all the principal stocks but he must also possess a prodigious memory; for, although he carries a little pad upon which all his transactions are recorded in duplicate, commissions will sometimes come so thick and fast that there is no time to make written records. Astonishing tales are told behind the windows overlooking the street of the wonderful prowess of certain brokers, of scores of sales made as rapidly as they could be acknowledged by a nod or a gesture, all completed without the slightest error, al-

though the sums involved represented thousands upon thousands of dollars.

The open-air brokers have at various times attempted to form an organization of some sort, in order to regulate the affairs of the Curb and to secure a building and the other paraphernalia which seem necessary for conducting an enormous volume of business; but on each occasion the Stock Exchange has interposed objections. The curb brokers, therefore, continue to inhabit the open street from 10 a.m. to 3 p.m. in all weathers, in the hot sun in the summer and swathed in coats and furs when the wintry blasts howl down between the tall building from Nassau and Wall streets. They have an unofficial sort of secretary, an unofficial publication for the record of their transactions, an unofficial gong to ring the hour of closing and an unofficial bulletin board for unofficial communications.

It is amusing to watch the bedraggled but animated groups in the street during those driving rainstorms which turn the New York gutters into sluiceways and against which umbrellas are worse than useless. The reaction to natural environment, of which biologists talk so much, seems to be entirely suppressed. A gentle old lady from the country expressed it all very fully. "Why," she said, "they don't seem to know it's raining."

FLEEING THE BROKERS

Most mining stocks sold on the New York Curb must be paid for in full. Some stocks can be bought on margin, but not generally. This is because the New York bankers, unacquainted even with good mining stocks, will not lend on them to the brokers. In Boston it is different. The bankers there are generally acquainted with the mining stocks listed on the Boston Exchange, and will loan on them to the brokers, who, consequently, are able to accept orders to buy on a margin. Boston brokers, however, do not commonly carry stocks that are dealt in only on the Boston Curb. Stocks are carried on the New York Curb by brokers who are able to finance them in special ways. However, marginal trading on the New York Curb is comparatively limited in volume.

The margin trick is a favorite one with sharpers who wish to enrich themselves at the expense of the Curb. One clever rogue a few years ago realized \$75,000 on a "plant" of this kind which cost not more than \$25,000. His method was fairly simple. He worked up a fictitious market on some worthless stock of his own manufacture. He then sent confederates to Boston, Philadelphia and other cities to open accounts with careless brokers. The confederates began by trading in good stocks, and after having established a credit, they placed orders for the bogus stock, putting up good margins, as high as 20 and 25 per cent. The out-of-town brokers bought the manufactured stock by

telegraph in New York, paying for it in full. The seller in New York was, of course, the arch conspirator. When enough stock had been sold on margin the confederates disappeared and the brokers were "stuck" with the worthless shares.

But it is not easy to catch the Curb brokers napping, and the sharper who succumbs in fleeing them is regarded in the street with respect not unmixed with admiration. In the new rule requiring unknown stock to be posted on the bulletin board the brokers have some protection against shares that are utterly worthless. The blandishments of the schemer of the ordinary sort have no more effect upon them than has the weather.

The Iron Industry in India

At one time the iron-smelting industry was widespread in India as is testified by the slag heaps found scattered throughout the country ("Sketch of the Universal Resources of India," by T. H. Holland). Small furnaces producing highly ferri-ficious slags which carried away the impurities were used. This was a very wasteful process and serves as no indication of the ore value in the country.

However, in the Raipur district of the Central Provinces in Mayurbhanj State large bodies of iron ore of a superior quality, in the form of small hills standing in relief from the general peneplane are found. The ore in these deposits runs as high as 68 per cent. iron with small percentages of phosphorus, and the deposits offer every facility for the cheapest form of quarrying.

Various attempts have been made to erect smelting plants on European plans the only successful one so far being at Barakar on the Raniganj coalfield. These blast furnaces turn out about 50,000 tons of pig iron annually. Steel making was attempted but proved a failure.

India stands in the front rank of the countries producing high-grade manganese ore. Practically all of the manganese ore produced, amounting in 1907 to 581,036 tons, is exported to the steel works of the world.

Indian Gold Mines

The gold production of the Kolar district in Mysore, India—including also the Hutti mine in the Deccan—in December was 52,759 oz. bullion, being 4480 oz. more than in November and 644 oz. more than in December, 1907. For the 12 months ended Dec. 31 the total was 549,731 oz. bullion in 1907, and 500,343 oz. in 1908; an increase of 10,612 oz. The bullion reported in 1908 was equal to \$10,424,667, or 504,300 oz. fine gold.

Economy as Related to Mine Accidents

A Fearless Discussion of the Lax Conditions That Exist, Showing That the Coal Operator Eventually Pays a Heavy Price for Present Neglect

B Y H . E . C O L L *

The relation of economy to mine accidents has not been given sufficient importance in the various articles and discussions concerning the heavy casualty list in the mining industry. Always to be remembered are the words of advice given by an old mine inspector of the Ninth Bituminous district of Pennsylvania in 1901, on the occasion of an examination for mine foremen. He summed up the whole situation in the words: "The safest mine must of necessity be the cheapest." There was no question about the old gentleman's sincerity, and there was no question in the minds of those new-fledged mine foremen as to the truth of his words, as they went about their duties; there also was no question as to the truth of the statement in the mind of the general manager, who hired the new mine foremen, and turned his mine over to them. They all sang the same doxology; they all preached the same gospel; but despite the fact that they were getting out coal at the lowest possible cost, men were still being killed.

Right here we have the nut cracked wide open. That ringing phrase, "the safest mine is the cheapest," becomes transposed in their minds to "the cheapest mine is the safest," and that transposition takes place so gradually, is so insidiously introduced, that before the changed thought takes conscious notice of the change, we are all hustling and bustling and hurrying to knock a quarter cent off the cost per ton. If someone halts us long enough to ask a few questions, we are always ready and able to put up an argument, showing that because the output has increased and the cost decreased, we have a much safer mine than previously.

We point with pride to the well planned haulage-ways, the heavy rails and well drained road-bed. We call attention to the fact that the men are kept off the operating roads in traveling to and from the faces. We can talk ventilation by the hour and show where we have provided considerably more than the law's requirements in amount of air per man. Airways are large and well kept. Overcasts are of masonry or concrete. Landings and turnouts are wide and everything possible is arranged to give quick and safe despatch to the coal. In fact the mine is considered a model one, and furnishes a fine subject for a well written magazine article by a proud official of the company—after being

carefully censored by the general manager.

That article, however, will have nothing to say about injuries and deaths during the past year. Of course not; they are accidents, due to the carelessness of the miner or his fellow workman. They are not a part of that splendid system of mining whereby we produce a ton of coal at less cost than we did before spending so much money to make a cheaper and consequently a safer mine. And in this attitude of the operator, the superintendent and the mine foreman, lies the whole secret of the fact that they get large output, low cost, well equipped mines, are having a higher injury and death rate than before we attained such skill in the science of mining.

It is not my intention in this article, however, to insinuate that mine officials generally are not anxious at all times for the safety of their men. The outsider does not realize what it means to the superintendent to receive that dreaded message "man killed," over the mine 'phone. The outsider does not know the "boss'" feelings as he gazes on what has been John Smith or Andy Kalenski, and asks himself the question, "am I to blame?" But the superintendent knows. Let us be charitable and not lay the blame on any individual. Let us rather take a lesson from Mr. Lawson and blame the "system."

THE MINER IS MADE RESPONSIBLE FOR HIS OWN SAFETY

Now the chief law of the system is that by improving the general efficiency of a mine, the same number of mine officials can govern a 1000-ton plant that formerly governed a 500-ton plant, and we find the miners backing that law as strongly as the operators. The only one left to fight the system is, as always, the outsider, and he knows nothing about the business. While this law has many ramifications, the dangerous feature about it is that the miner is practically made responsible for his own safety. A few rules and regulations have been passed by various legislatures which are supposed to govern his actions, while working as a miner or other underground employee. To these are added a few additional rules to cover special methods or practices at any particular mine.

The majority of these rules are good and if faithfully followed would no doubt save many a broken bone; however, so long as we have to contend with the vagaries and forgetfulness of 500 different human natures we are certain to have dis-

obedience both intentional and unintentional. A miner may fire shots, put up timber, pull posts or do any one of the many things which yearly levy a heavy toll on human life; however, because he is a contract man it is assumed that he is capable of protecting himself; the miner always says he is capable and prefers not to have any bosses around bothering him as to how he is doing his work. What is the result of this mutual understanding whereby two or three officials are able to handle a mine turning out 1000 or 1500 tons of coal per day?

Let us take the record of the anthracite field for 1906:

Causes of Death.	Percentage.
Falls of roof and coal	47
Premature blasts	12
Explosions of gas	9
Powder explosions	6
Mine cars	15
All other causes	11
Total	100

Note that 59 per cent. of the accidents occurred directly at the working face. Contract work was directly responsible for 74 per cent., and 47 per cent. which were due to falls of stone and roof; are classed as accidents due to the ignorance, inexperience or carelessness of the miner; as the latter is usually dead, he can be safely blamed for the unfortunate occurrence.

Foreigners, a few weeks "over," are hired as miners and sent to the faces without the mine officials knowing whether they are competent or not. Men whose judgment we would not trust in anything else are sent into working places and left to themselves to do work that requires close attention and common sense.

What is to be said of a practice or a system that permits 47 per cent. of its total number of accidents to be caused by lack of precautionary measures at the working face? Every miner puts up the timber for his own safety. The miner puts up the timber he considers necessary, and the company accepts the miner's judgment. The result is—broken backs, crushed heads, and all the long list of things that will kill or cripple a man.

MANY ACCIDENTS ARE CAUSED BY THE DRAWING OF PROPS

In the working of pillars this is usually due to the drawing of the props or supports, and it is here that the bituminous mines run up their long heavy death rate. Chief Inspector Roderick, of Pennsylvania gives the number of deaths due

*Mining engineer, Stellarton, Nova Scotia.

to falls, during 30 years of bituminous mining, as being 60 per cent. of the whole. During 1907 he shows that 41 per cent. of the fatal accidents were due to the carelessness of others and that nearly 20 per cent. were due to unavoidable causes. Now if we get close down to the methods adopted in getting a ton of coal from the face to the surface and consider the various rules and provisions that are supposed to be in force for the protection of the men, it is difficult to understand why we have unavoidably killed a man for every million and a half tons of coal produced.

The report of the Geological Survey for 1907 gives the following statistics in regard to accidents: The total number killed was 3,125, and 5,316 were wounded. Of these totals, 11,22 were killed by falls of roof and coal and 2,141 persons were wounded. Powder accidents caused the death of 201 men and injured 416, while explosions from gas and dust killed 947 men and wounded 343. Many of the 3,263 accidents from falls of roof and coal could have been prevented by an intelligent supervision of the working face. A large number of the 617 powder accidents would not have burned and scarred their victims had a competent man inspected and fired each shot.

Chief Roderick in his report on the mining industry in the State of Pennsylvania, speaks of the 1907 output as being most remarkable, and Mr. Roderick may well be excused for his pride in a State that can produce more coal than any foreign nation, except Great Britain. But more remarkable than the output is the candid nature of the chief's remarks on accidents. Here we find the head of the Mines Department of the greatest coal-producing area in the world, calmly producing the following:

"However, after the last word has been said regarding the causes of accidents and the best means of prevention, it still remains an indisputable fact that over one-half of all fatalities result from carelessness on the part of the victims or on the part of others, and such being the case, the statement must go unchallenged, that the loss of life, deplorable as it is, will continue until the miners themselves and those in charge of the workmen learn to exercise greater care, or are better fitted for their work." After catching his breath the worthy chief winds up by declaring that "the spirit of recklessness and the ignorance of the workmen add an unusual hazard to an occupation that at best is notoriously dangerous."

Now why does Chief Roderick call an occupation "notoriously dangerous" when over half the accidents are due to lack of discipline on the part of miners and mine officials, lack of nerve on the part of mining engineers, and total lack of capacity on the part of the State of Pennsylvania, for understanding that something

more was expected of her than the killing of a man for every 180,000 tons of coal produced?

Particular reference is made to Pennsylvania because being the heaviest producer, that State should show the lowest percentage of deaths. While it is true that anthracite mining is more dangerous than bituminous, it has no result on the death percentage, since we find in 1906 the bituminous rate was almost as high as the anthracite, while in 1907 it exceeded it. Nature has singularly favored Pennsylvania in the laying down of the soft-coal beds. Very productive seams of clean coal, lying almost flat with a light cover, are conditions which allow for a large output being readily obtained at a low cost, but for the same reasons it should mean a low death rate.

IF WE LEVY A FINE FOR EVERY FATAL ACCIDENT

Because reverse conditions are found to be true, we are forced to the conclusion that something is seriously wrong in the coal-mining industry. In order to ferret out this wrong let us assume a certain condition: Supposing a fine of \$3000 be levied on a coal company for every fatal accident, thus making a direct loss to the company for every loss of life. That concern would immediately take up the question of prevention of accidents, and the investigation would at once lay bare three fundamental causes of mine accidents:

1. Lack of discipline owing to there not being a sufficient number of officials to properly oversee the men and their work.
2. The use of open lights or, where used, the improper handling of safety lamps.
3. The use of explosives which will not insure a minimum risk.

The first cry of the operator will be that the coal business cannot stand under any change in these conditions and that his increased costs will eat up the profits of the business. Let us see. In the first place you can't kill a man for nothing. Your accident and property insurance rates are high or if you don't carry accident insurance you are liable to be mulcted in a damage suit by a lot of farmers or business men who have not the least idea of what a mine is. Also your friends the lawyers don't work for nothing. The item, which, outside the loss of life should receive the most consideration, is the damage done to mines and mining property during the past two years by fires, explosions and water. The majority of these can be traced back to some one of the fundamental wrongs of the mining industry, lack of discipline, the misuse or nonuse of safety lamps, and the powder question. This means that accidents have a definite cost per ton, so that if we spend, in accident-preventing measures, a sum equal to the cost of our accidents, we will put a stop to the death rate and at the

same time add nothing to our cost, or what is more than likely decrease the cost. For there can be no question but that, if the miner and the laborer are in constant supervision, and if they know their work is going to be inspected and passed upon two or three times in the day, it is going to certainly follow that more efficient and consequently more productive work will be performed.

The discipline question is really the only one which could be a factor in costs since it can easily be shown that safety lamps and powder should have no bearing upon it. As regards the former, no man today is justified in using open lights in any coal mine. The history of the industry in England, Wales, United States and Canada, is full of disasters brought about or aided by the open light. What power is it that still keeps this danger in use? Certainly it is not the man who has become accustomed to safety lamps. There is no comparison to be made in point of safety, comfort, or cleanliness.

THE DANGERS FROM FLAMING EXPLOSIVES

Powder bears such an important part in the mining industry, and its use is so extended that it is difficult to understand why it is only at this late day, the proper explosive for mining coal, and the methods to be adopted in its use are being discussed and investigated. The moment you bring any explosive into a mine, the factor of safety of that mine is decreased, proportioned by the nature of the explosive, the condition of the mine and the discipline maintained. Therefore, it follows, that given the necessity of explosives in the mining industry, only such compositions should be permitted as would, after scientific experiment and practical use, insure the highest possible factor of safety. The science of mining has signally failed to rise to the opportunities presented, through the use of explosives, and has caused a consequent delay to the progress of mining coal in a safe, scientific and economical manner.

We find both capital and labor standing shoulder to shoulder, the one prepared to lose his mine, the other his life rather than admit that some other explosive would answer his purpose as well as their beloved black powder. There are three heavy-weight reasons given against the use of high explosives in mining coal:

1. Much higher price per pound.
2. Increased quantity of fine coal.
3. Greater liability to accidents in the handling of high explosives.

As regards price, if the operator will deliver powder at what it costs him in his magazine, the miner can afford to pay for a much higher grade of explosive and mine coal at a decreased powder cost per ton. In any case the profit was a "false profit" for whatever you received in the pound of powder you paid out for the ton of coal. The argument that the high ex-

plosive shatters the coal more than black powder is the strongest one against any change in explosives.

The foregoing argument is surely based upon a mistaken idea. There are explosives manufactured today that are almost as slow as powder, yet they have double and triple the strength. Put in shot-firers, men who understand their business; let them regulate the placing of the shot, depth of hole and weight of charge; allow no shot to be fired which has not been sheared or undercut, or has its equivalent in two open faces, and lastly, fire all shots with a battery, and the operator will find no increase in fine coal. Instead, he will have taken a long step toward cutting down the accidents, and preventing fires and explosions.

TREAT DISOBEDIENCE AS A CRIME

Such changes as are made should be covered by special rules, approved by the Mines Department and made a portion of each State's regulations. Armed with this, the officials and workmen should be taught that disobedience and evasion of mining laws are to be treated and punished as crimes.

There is one feature that would have more bearing than any other on general conditions and mining practice: that is, the education of miners by mine officials. If there are sufficient officials to keep in touch with the workmen, and exercise a supervision over all the actions of the miner, much better results would be obtained in the use of explosives, timbering, track laying and the quality and quantity of coal produced per miner. Every official should constitute himself a walking instructor, leaving a word of advice here, and commendation there. He should not only be able to answer, but what is more important, he should be able to ask questions.

The writer realizes that in bringing up these questions he is treading upon the corns of almost every coal operator on the continent. It is a noticeable fact that every available feature of last year's heavy explosions has been made the subject of lengthy discussion and dissenting articles. But there is no dissention when it comes to the possible influence that discipline, or explosives may have had on these accidents. The U. S. Government gets into a flutter and consults foreign experts after gas and dust explosions have killed 947 men and injured 343 others, but we find 1122 men killed and 2141 injured by falls, and not until recently were any articles written, or voices raised in protest.

Big explosions appeal to the imagination and excite great discussion as to whether it was gas, dust, or both; but day in and day out they can be crushed and maimed by ones and twos at the "faces." Year after year this has occurred and no mining society has discussed it, no State has said, "this must stop." no

jury has said to the operator, "you are responsible, and why? Because these accidents, which cause more deaths, more injuries, more suffering, more poverty, than any other type, occur almost exclusively to contract men, and are accompanied by a small property loss.

Who can estimate the moral loss to the mining industry? The lack of supervision shown by these figures must indicate a lack of mine efficiency, that will affect the output from the time it is mined at the face until it is dropped into the cars. Increase the productiveness of the working face and the costs are bound to come down.

MINING OPERATORS ARE INDIRECTLY PAYING THE PRICE

Surely the time has come when coal operators must open their eyes to the fact that they are indirectly paying the piper for all these accidents. Equip your mine as well as you can, model it after the best and then improve on that, but so long as your officers have not established a just, but withal, an iron-bound discipline, you cannot expect to take the proper advantage of your costly improvements, in a decreased cost per ton. Discipline is to productiveness, what charity is to faith. As St. Paul says, "Without it you have nothing."

It is the operators' fault today that mine discipline is not on the same plane as that maintained by the captain over his crew. The very fact that there are so many foreigners among the miners, would make this easier, since they are naturally amenable so long as there is no imposition. But there is no excuse today for keeping an official who will not give a "square deal." Start in by endeavoring to lessen the casualty list. You may have to change your officials, put in safety lamps, use a powder with a higher factor of safety, and do many other things that apparently are going to cause you an increase in cost, but it will surely follow that as the accident list grows less, the general efficiency of your plant will increase, and at the end of a few years, the accounts will show, that, to economize in blood is to economize in costs, that a safe mine is indeed a cheap mine and that the dark days are over, when this industry, so closely linked with the greatness of our country can be called "notoriously dangerous." The safest mine is the cheapest.

Considerable concentration was done on the Rand, South Africa, before the war, and even for some years after the war at a few properties. But finally it became the general opinion that concentration did not pay in treating the Rand ores; so at present Frue vanners and other concentrating devices have been discarded and, as no concentrates are obtained, chlorination has been abandoned. At present the Rand ores are treated only by amalgamation and cyanidation.

The Coal Production of Oklahoma in 1908

SPECIAL CORRESPONDENCE

The coal production in Oklahoma for the 11½ months ending Oct. 31, 1908, was, according to the report of the State coal mine inspector, 2,724,832 tons; the estimated value of this output was \$6,130,872, or \$2.25 per ton mine-run. There were 137,909 kegs of powder used, making an average of 19¼ tons of coal mined for every keg of powder used. In producing Oklahoma's output, 14,560 men were employed; of this total 8629 were miners, 3928 were company men employed in the mine, and 2003 were outside men. There were 44 fatal accidents, or one fatal accident for every 61,928 tons of coal mined; there were 128 nonfatal accidents, or one for every 21,287.96 tons mined. For every 1000 employees 4.39 were killed. There was a general cessation of coal mining throughout the entire State from April 1 to May 25, on which latter date a contract was agreed to by the miners and operators.

Gold in the Netherlands East Indies

At the Keta-Loen mine in Celebes, the preliminary report for 1908, according to the *Indische Mercur*, shows that 39,670 tons of ore were mined and crushed during the year. From this ore there was won 25,773 oz. gold and 38,140 oz. silver. The total value of the metals was \$536,268, and the estimated profit was \$206,000. The ore reserves at the close of the year were 162,000 tons, of an average estimated value of \$15 per ton.

The Reljang-Lebong mine, in Sumatra, on the same authority, mined and treated in 1908 a total of 89,760 tons of ore, yielding 82,868 oz. gold and 471,630 oz. silver. About 40 per cent. of the metals was obtained by cyaniding tailings. The value of the metals won was \$1,909,000, giving an average return of \$21.27 per ton. The estimated profit for the year, after deducting working expenses was \$1,287,000. The ore reserves at the close of the year were 308,000 tons, of an estimated value of \$20 per ton.

The amalgamation plates in the Bantjes mill on the Transvaal, South Africa, instead of being placed immediately below the batteries, are to be placed in the extractor house.

In stamp-battery construction the tendency on the Rand is to increase the weight of the stamps, to make larger the crushing surface of the stamp shoes, and to enlarge the mortar boxes.

New Resistance and Induction Furnace

By DR. ALFRED GRADENWITZ*

The electric furnaces hitherto designed for the manufacture of iron may be divided into three classes, according as they are based, (1) on the action of the electric arc, (2) on the heating effect of electrical resistances, or (3) on induction effects. A new electric furnace recently installed in some of the German iron works is a combination of the resistance and induction furnaces.

thrown into the primary coil, any special interrupting device may be dispensed with.

bath of molten iron, inclosed within the masonry ring *m*.

THE KJELLIN FURNACE

In order to appreciate the working of induction furnaces it should be understood that, apart from certain unavoidable losses, the flow developed in the secondary conductor, i.e., the product of the amperage by the tension, is equal to the flow traversing the primary coil. However, either of these two factors can be altered at will, by properly designing the number of coils, and the cross-section of each coil. A high-tension current of low amperage thrown

THE NEW FURNACE

These induction furnaces are very convenient for the melting of steel from pure, raw materials, without any special refining, and are used to great advantage whenever a steel of given composition is to be produced from pure pig and scrap iron, the percentage of carbon in the former being diluted by the scrap, and the finished product being alloyed with any desired metals, such as nickel, chromium, tungsten, etc., to give the steel spe-

RÖCHLING-RODENHAUSER ELECTRIC FURNACE

In order to explain the working principle of the new furnace the Kjellin induction furnace, designed on the model of an alternate current transformer, will first be briefly described. Fig. 1 is a diagram of two coils of wire, insulated from each other, one of which is traversed by a primary electrical current, inducing in the other coil a secondary current. If a soft-iron core *k*, a bundle of iron wires, is introduced into the primary coil *n* and the current of the latter is interrupted in rapid succession, the effect of the primary coil on the secondary coil *s* will be considerably reinforced. If, then, instead of a continuous current an alternate current is

into the primary circuit can thus be used to excite a low-tension current of high amperage in the secondary coil, provided that the latter, as illustrated in Fig. 1, is made up of a few windings of relatively large cross-section. By further reducing the number of turns of the secondary conductor, the limit represented in Fig. 2, i.e., a simple ring conductor, is reached, which under proper electrical conditions may be loaded with reduced currents of such volume as to be raised to a white heat and melted. This, in short, is the principle underlying the Kjellin induction furnace, as shown in Fig. 3, *n* being the primary coil, *k* the iron core, and *s* the secondary coil, constituted by a circular

cial properties. If, however, the induction furnace is used for the refining of impure molten material from converters or air furnaces, it is found to prevent some disadvantages which are overcome in the new arrangement. This new furnace was designed by Röchling-Rodenhauser, and is a combination of the Kjellin induction furnace and the resistance furnace.

As shown in the diagram, Fig. 4, two Kjellin furnaces are connected in the form of a figure eight, *n* being the primary coil, and *k* the iron core. In order to allow the central communicating part of the two channels *s'* to be given a width sufficient for convenient operation, the space within the masonry *m* is further

*Berlin, Germany.

heated by electric resistances inserted between the current conductors *c*, which in the present case consist of conductors of the second class. The current used in heating these resistances is supplied by an additional secondary coil *s*, fitted over the core *k*. The accompanying illustration shows a furnace of this type of 3.5 tons capacity.

As regards the details of construction of the new furnace, it may be said that means for completely discharging the furnace had to be provided by designing it as a tilting furnace, to be able to remove any excessive amount of slag, and to be independent of tap holes. The furnace is suspended upon two pivots, and its spout is raised or lowered by tilting the whole in the usual way. All parts had, therefore, to be more substantial than in the stationary Kjellin furnace.

As regards the current consumption of the furnace, this may be said to be rather favorable, about 385 kilowatt-hours per ton being used in a small 300-kg. furnace, for melting pig iron and heating it to about 1200 deg. C., whereas for finishing a scrap charge about 600 kilowatt-hours are

report provoked a heated discussion bordering on threatening trouble. The report of the committee, however, was adopted by the convention. Day after day the delegates anticipated a report from the tellers appointed to count the vote for national officers, but no report was made. It was learned, however, that Mr. Lewis had been elected with 16,200 votes to spare and all interest in the election subsided.

When the miners met January 19, it was expected they would complete their work and adjourn not later than January 30. Now there is some doubt whether they will be able to get through in another week. It is possible, however, if the clashes cease the work will be completed in that time.

Copper Imports and Exports

The movement of copper to and from the United States in the year 1908, as reported by the Bureau of Statistics of the Department of Commerce and Labor, showed an increase of 59.2 per cent. in exports; a decrease of 13.4 per cent. in im-

ports; 2; British North America, 55,367; Mexico, 7060; other countries, 552; total, 63,149 tons.

IMPORTS

The imports of copper in metallic form were, in pounds:

	1907.	1908.
Great Britain ..	25,706,852	5,434,435
France ..	696,662	165,506
Germany ..	6,814,338	1,451,370
Other Europe ..	5,616,261	13,359,117
British N. America ..	30,902,596	30,895,737
Mexico ..	76,741,532	45,742,993
Cuba and W. Indies ..	1,168,769	534,050
Peru ..	14,945,697	23,646,921
Other S. America ..	8,519,374	2,418,672
Japan ..	9,809,569	8,329,806
Other countries ..	12,239,617	32,242,447
Total	192,901,267	162,224,144

The marked changes were the decreases in receipts from Europe, from Mexico and from South America outside of Peru; the increases from Peru and from the non-enumerated countries.

The copper contents of ore and matte imported were, in pounds:

	In Matte.	In Ore.	Total.
British N. America ..	2,859,969	8,326,728	11,186,697
Mexico ..	128,766	15,775,626	15,904,392
South America ..	9,764,852	9,054,852	18,819,704
Other countries ..	4,983,372	15,452,890	20,436,262
Total	7,677,307	48,610,096	56,287,403
Total, 1907	59,718,587	59,718,587	

FIG. 1

FIG. 2

FIG. 4

required. While the direct melting of pig iron in this furnace would hardly pay in Germany, it is used to advantage in handling molten Thomas or Martin steel, and refining it to the finest grades of steel, which may be said to be the proper province of the electric furnace at present.

Coal Miners' Convention

SPECIAL CORRESPONDENCE

The end of the second week of the annual convention of the Mine Workers' Association finds the delegates still inharmonious and little of the legitimate and necessary work of the meeting has been accomplished. These matters are a source of worry to President Lewis who is meeting with strong opposition at every step of his administration by the Walker faction. The convention is costing the association \$9000 a day and this reminder has had no effect upon the dilatory work of the various committees and their tardy reports. President Lewis made his annual report early in the week and the committee to which it was referred approved it. This

ports; and an increase of 165 per cent. in the excess of exports over imports.

EXPORTS

The exports of copper for 1907 and 1908 were as follows, in pounds:

	1907.	1908.
Great Britain ..	81,409,441	117,810,314
Belgium ..	3,822,551	5,560,366
France ..	93,075,145	115,690,381
Germany and Holland ..	164,259,660	333,016,011
Italy ..	21,100,000	25,512,267
Russia ..	4,341,386	4,657,077
Other Europe ..	26,221,024	39,433,674
British N. America ..	3,747,410	3,977,142
Mexico ..	362,411	35,895
China ..	10,003,592	13,735,899
Other countries ..	493,873	2,447,101
Total	408,929,401	661,876,127
In ore and matte ..	15,328,500	13,632,300
Total	424,257,901	675,508,427

Germany and Holland are included together because most of the copper reported as shipped to ports in the Netherlands is intended for Germany; railroad connections to many German points being better from Rotterdam than from Bremen or Hamburg. Our custom-houses report, of course, only the seaport to which metal is directly consigned. The copper contents of ore and matte are estimated on the basis of values. The actual tonnages in 1908 were: To Great Britain, 168; Ger-

In 1907 ore and matte were not reported separately. The actual tonnages in 1908 were: British North America, 3177 matte and 137,663 ore; Mexico, 816 matte and 54,073 ore; South America, 22,790 ore; other countries, 7075 matte and 62,423 ore.

These figures give the following totals for copper imported, reexports of foreign material being deducted.

	1907.	1908.	Changes.
Metal	192,901,267	162,224,144	D. 30,677,123
In ore & matte ..	59,718,587	56,481,343	D. 3,237,244
Total	252,620,054	218,705,487	D. 33,914,567
Re-exports	993,555	718,941	D. 274,614
Net imports ..	251,626,499	217,986,546	D. 33,639,953

A large part of the imports consisted of copper sent here to be refined and put in final marketable form.

COMPARISON OF EXPORTS AND IMPORTS

The total exports and net imports for two years compare as follows:

	1907.	1908.	Changes.
Exports	424,257,901	675,508,427	I. 251,250,526
Net imports ..	251,626,499	217,986,546	D. 33,639,953
Excess, exp. ..	172,631,402	457,521,881	I. 284,888,479

In addition to the quantities reported above there were exported manufactures of copper in various forms valued at \$5,888,170 in 1907, and \$3,162,303 in 1908; a

decrease of \$2,725,867. The quantities and forms of these manufactures are not given.

The Guggenheim Exploration Company

The annual report of this company for the calendar year 1908 shows liabilities and assets as follows:

Capital stock.....	\$22,000,000
Bills and accounts payable.....	1,003,531
Surplus.....	13,643,689
Total liabilities.....	\$36,647,220
Treasury stock.....	\$ 1,319,900
American Smelters Securities Co. (A).....	13,860,000
American Smelters Securities Co. (B).....	199,890
American Smelters Securities Co. Common.....	1
Other properties and investments.....	17,589,487
Furniture, fixtures and equipment.....	5,766
Bills and accounts collectible.....	2,083,436
Cash and demand loans.....	1,586,800
Total assets.....	\$36,647,220

A detailed statement of assets included under other property and improvements is as follows: Cumberland-Ely Copper Company, \$912,808; Esperanza, Ltd., \$337,360; Nevada Consolidated Copper Company, \$1,671,589; Nevada Northern railroad bonds, \$1,650,000; Utah Copper Company, \$4,788,648; Yukon Gold Company, \$8,222,062; miscellaneous, \$7020; total, \$17,589,487.

The report says: "Comparison with last annual statement will show decrease in surplus of \$100,563. The net income was \$57,846 in excess of dividends, but we charged off \$158,412 on account of securities disposed of during the year. We continue to carry American Smelter's Securities Company common stock—of which we own \$11,249,000, par value—upon our books at a nominal valuation of \$1. It is only within a few months that all of the smelters and refineries of the Securities company (six in number) have been completed and in operation. The profits now earned by the Securities company indicate that its common stock will in the course of time be a very valuable asset.

"Calculating the value of American Smelters Securities Company (A) shares, upon which dividends are paid at the rate of 6 per cent. per annum, at \$90 per share, and the remainder of our stock holdings, (exclusive of American Smelters Securities Company common) at their present market prices, the book value of Guggenheim Exploration Company stock would be \$230 per share, exclusive of good-will. Assuming the present value of American Smelters Securities Company common to be \$40 per share, the book value of Guggenheim Exploration Company stock would be \$251 per share, exclusive of good-will.

"Last year we stated that in the opinion of our engineers Utah Copper, Nevada Consolidated Copper, Cumberland-Ely Copper and Yukon Gold companies would

probably earn dividends during the year 1908. This prediction has been practically realized. Utah Copper Company commenced dividend payments in the third quarter of last year upon a basis of \$2 per share. Its present earnings are in excess of \$3 per share.

"The Nevada Consolidated and Cumberland-Ely Copper companies were both more or less delayed in the completion of their equipment, but have been making regular shipments since August, and their output and earnings are increasing steadily from month to month. Both give promise of dividend returns to their stockholders beginning in the last half of the year 1909.

"The Yukon Gold Company recently issued to its stockholders a circular letter concerning its operations. It is the intention of the copper companies in which we are interested to inaugurate a system of issuing quarterly statements, copies of which will be mailed to our stockholders."

The Proposed New Testing Machine

A bill is now before Congress to authorize the making of a contract with A. H. Emery, of Stamford, Conn., to construct and erect a great testing machine, on the lines of the well-known machine made by him some 30 years ago for the Watertown arsenal, and still in use. The new machine is to be very much larger than the Watertown machine which has a capacity of 800,000 lb. The proposed machine shall be able to give and weigh loads of tension up to 5,000,000 kg., or 11,000,000 lb., and loads of compression up to 10,000,000 kg., or 22,000,000 lb., on specimens up to 100 ft. or more in length. The main loading platforms for testing bridge-compression members, columns, and so forth, shall be not less than 8 ft. wide and 12 ft. long, and shall be adapted to receive auxiliary holders and platforms.

The machine shall be provided with tension holders, to seize and test to destruction round, square and rectangular bars, with loads up to 1,500,000 kg., or 3,300,000 lb., with lengths up to 100 feet or more.

It shall be provided with a pair of holders for testing bridge links up to 100 ft. or more in length, with all loads up to 5,000,000 kg., or 11,000,000 pounds.

It shall be provided with an auxiliary pair of compression platforms with hardened faces for testing stone, and similar material with all loads up to 10,000,000 kg., or 22,000,000 pounds.

It shall also be provided with a pair of auxiliary platforms, with pins 24 in. in diameter and 8 ft. long, for testing pinned columns with loads up to 10,000,000 kg., or 22,000,000 pounds.

There can be no question that this machine will be of very great service to en-

gineers and bridge-builders, and that it will be worth far more in the end than the \$1,750,000 which it is proposed to pay for it. There is no machine now in existence anywhere in the world capable of making the tests of structural members which are proposed, and the exact information which it will furnish will open new opportunities to all who are concerned in the erection and stability of great steel structures.

American Smelting and Refining Company

A statement issued to the stockholders of the American Smelting and Refining Company on Feb. 8 gives the assets and liabilities of the company on Oct. 31, 1908, and earnings for the first six months of the fiscal year, which are in excess of 8 per cent. per annum on the common stock.

President Daniel Guggenheim states: "The business and earnings of the company declined from the beginning to the end of the fiscal year ending April 30, 1908. Since the beginning of the present fiscal year, however, the earnings have been gradually improving month by month. The company has not, in the past, issued reports to the stockholders with reference to the business of the company oftener than at each annual meeting, principally for the reason that it is both difficult and expensive to accurately cut off the business oftener than once a year, on account of the large value of precious metals in process of smelting and refining. The directors believe, however, that the desire of the stockholders for accurate reports as to operations and profits of the company as often as is practicable is warranted."

The profit and loss statement for the six months ending Oct. 31, 1908, follows:

Net earnings from operations.....	\$3,917,684
Construction and improvements.....	75,923
	\$3,841,761
Dividends:	
Preferred, 3 1/2 per cent.....	\$1,750,000
Common, 2 per cent.....	1,000,000
	2,750,000
Net surplus to profit and loss.....	\$1,091,761
Assets and liabilities on Oct. 31, 1908, were	
ASSETS:	
Property.....	\$86,845,676
Investments.....	2,858,617
Metals (refined value).....	18,218,785
Material.....	1,249,250
Cash and demand loans.....	8,629,550
Total.....	\$117,802,184
LIABILITIES:	
Capital stock.....	\$100,000,000

Colliery Notes

In using reinforced concrete for construction work about mines, it has been found that in concreting steel posts, the adhesiveness of the concrete is greatly increased by wrapping the posts and struts with iron or steel wire.

The amount of ash that any coal will yield, depends largely upon the rapidity with which the coal is burned. When a coal is burned slowly under the influence of a moderate draft, the ash will remain pulverulent, and will pass through the grate as formed. When coal is used for industrial purposes, however, rapid combustion usually takes place, and under these conditions, nearly all coals will yield ashes which fuse, thus forming clinkers.

From the advance proofs of the tables of fatal accidents in and about the mines of the United Kingdom during the year 1908, we obtain the following figures:

Cause of Accidents.	Total Killed.
Explosions of firedamp or coal dust	128
Falls of ground	586
Shaft accidents	83
Underground haulage	221
Miscellaneous underground	143
Total underground fatalities	1161
Miscellaneous surface	145
Gross total in 1908	1306
Total in preceding year	1243

Many superintendents do not use sufficient discretion in the selection of men to draw timbers when robbing work is being carried on. Only skilled men selected for their coolness, resource and courage should be employed to perform this work. These men should be paid good wages, and under no circumstances should they be put on piece work, for when this latter plan is followed, the men always take risks which otherwise would not be attempted.

Every coal company should carefully experiment so as to have on record the approximate space occupied by the different sizes of coal they produce. As a general rule, 2000 lb. of broken anthracite coal will occupy about 35.5 cu.ft. of space; 2000 lb. of Clearfield bituminous coal will occupy 33.55 cu.ft. of space; 2000 lb. of New River bituminous will occupy 40 cu.ft. of space, while the same weight of Pocahontas bituminous will occupy only 34 feet cubical area.

At one of the larger mines on the continent, where reinforced concrete timbers are used instead of wooden props, it has been found that the concrete supports do not occupy extra space and cost from 10 to 15 per cent. less than ordinary timbers. The concreting of steel headframes has been tried successfully, and it was found that concreting the steel posts not only protected them from corrosion, but put a stop to the constant vibration of the headframe while in use.

Most of the safety catches that are designed to prevent shaft accidents, are correct in theory but disappoint in practice. A recent case occurred where one catch operated on one side of the cage, while the corresponding catch on the other side did not act; as a consequence the cage was overturned. One engineer in discussing this subject says, "it is improbable that four catches—two on each side—could be brought to operate simultaneously; if they did not, their utility was gone."

Only a short time ago, mining experts in England after experimenting with stone dust mixed with coal dust, stated that underground areas so treated would not sustain a dust explosion. M. Barthou, minister of public works in France, now asserts that 40 per cent. of schist dust, mixed with coal dust renders the latter free from the danger of explosion. He further states that deposits of schist dust at intervals in a mine, will make it possible to restrict fires to a limited section of a shaft or gallery.

Coal-cutting machines are subjected to unnecessary strain when they are compelled to cut over an uneven face. If the work is properly blocked out, one machine with three attendants will do as much work as 20 men by hand labor. One great objection to the use of mining machines is the scarcity of suitable men to work the machine. The man who operates a coal cutter should combine the qualifications of a practical miner and a mechanic. It is a fact, however, that those with mechanical ability prefer to work above ground, so that it is necessary to train miners for the work.

In approaching a fault in a coal seam, much care must be exercised if we are to correctly determine the throw of the seam. The majority of faults slope, but in some cases, vertical faults are found. It is usually true that the roof and coal are of poorer quality when a fault is being approached; it also frequently occurs that water and gas are encountered under such conditions. As a general rule, if the coal first terminates at the top, the seam should be looked for lower down, and *vice versa*. Drilling should then be resorted to and an up or down entry only driven after the coal is located or all other cheaper methods of prospecting have been tried.

The construction of rectangular coke ovens in the Connellsville region is becoming more general, and it is probable that the old style beehive oven will no longer be introduced in the newer operations. The labor question is a serious problem in the ccke region and if the rectangular oven requires less men to operate it, this style of oven is, therefore, likely to simplify the labor problem. The new-style oven under construction and in operation will average about seven tons, which is an increase over the old-style fashion of burning coal. In these new type

ovens, the coal is mechanically ejected at one operation, and is thrown upon a conveyor, continuous along the string of ovens, which dumps directly into the cars. In this oven, extra sprinkling is required but the quality and tonnage of coke is increased and briaze is almost entirely eliminated.

Although electricity is the source of power principally used in underground haulage, it is sometimes necessary in gaseous mines, to eliminate all fire risks. One of the largest and most gaseous mines in western Pennsylvania has recently installed 8 compressed-air locomotives. In this mine, the operating conditions require that heavy loads be hauled up grades as steep as 5 per cent. and around curves of 100 ft. radius. The clearance limits were so restricted that it was found impossible to design a single locomotive capable of meeting the conditions. The locomotives, therefore, were arranged to be operated in tandem, and are coupled together back to back, so that one operator can control the two units by a single throttle lever, reversed lever, brake valve, etc.; by means of a flexible connection between the air tanks, the locomotives can be charged simultaneously. When the locomotives are in operation, this flexible connection is closed, but the auxiliary air tanks are then in communication through a rubber hose coupling, so that the cylinder pressures on the two units are equalized. This pressure is maintained by the reducing valves at 150 lb. per square inch, the initial pressure in the storage tank being 800 lb. per square inch.

Every mine superintendent should be prepared at all times to act with expediency in case of a mine fire. It is most advisable for the officials of the company, in developing a mine, to occasionally formulate fire plans, by dividing the mine into districts and selecting proper locations for dams. It should also be remembered that the selection of a panel system of working is not only for the better protection of the mine in case of an explosion, and for more efficient ventilation, but such a system of working by districts greatly reduces the liability of an underground fire spreading. The underground development should be so planned by the mine engineer that convenient and safe locations will be provided for the erection of fire dams in case of necessity. At least 30 ft. of narrow entry is necessary for the location of a substantial dam. In fighting a mine fire recently, four large dams were built; the longitudinal section of one of these stoppings was as follows: 3 ft. 9 in. small firebrick, 2 in. cement, 3 ft. 9 in. firebrick, 9 in. large firebrick, 12 in. concrete, 2 ft. 3 in. retaining wall, 7 ft. dirt, 3 ft. brick and mortar, 4 ft. 6 in. dirt, 2 ft. 6 in. brick and mud. This stopping, therefore, was 28 ft. 8 in. in length, and was found to be no larger than conditions made necessary.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Pres. and Treas. ROBERT McKEAN, Sec'y.
565 Pearl St., New York.

London Office: 6 Boulevard Street, London, E. C. 4, Eng.
CABLE ADDRESS: "ENGINEERING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 10 francs. Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.
Our circulation for January, 1909, was 54,000 copies.

February 6, 1909, 12,000

February 13, 1909, 10,000

None sent free regularly, no back numbers. Figures are live, not circulation.

Copper Statistics

The first report of the Copper Producers' Association is as follows:

	Pounds.
Stock of marketable copper, Jan. 1, 1909, 122,367,266	
Production during January, 112,135,269	
Deliveries for consumption and export, January, 99,362,421	
Stock of marketable copper, Feb. 1, 1909, 144,159,045	

The above figures represent the production by the refiners and the stocks in their hands.

The Situation in Copper

The reduction in the price, last week, of a leading selling agency to 13½¢, delivered, 30 days, corresponding to about 13¼¢, cash, New York, had no effect upon the market. Other agencies had previously been selling at the same figure, and even lower. Some had been maintaining a nominal asking price of 14½¢, without making any sales, because those offering at lower prices were taking the business. If these holding aloof had entered the market in a competitive way, the result would have been, of course, demoralization.

It is erroneous to believe that there is ever a complete cessation of business in copper. The number of manufacturers requiring it is so large, that some one must be in the market nearly all the time, while the production to be sold, nearly 4,000,000 lb. per day on the average in this market, is so large that someone must sell something. However, when the demand is very light, as it has been for a month back, the business offered is taken by those who are willing to make concessions.

Under these conditions there was nothing particularly to be gained by the interests previously holding aloof in reducing their price only to the current market. If consumers had been of a mind to consider that price a bargain, at which they would have been willing to take over large quantities of the metal, things would have been different. It has now been demonstrated that they were not of that opinion, for very little buying has been done since Feb. 2.

It is no longer to be disguised that the situation in copper is precarious, with a tendency toward lower prices. What the Producers' Association has reported as to stock on hand will not make any great difference, inasmuch as the well-informed, both among producers and consumers, have all along been acting on the belief

that the stock on Jan. 1 was about 130,000,000 lb. The exaggerated estimates never commanded any attention except among the outside speculative interests.

Consumers do not buy, but production is going ahead at the largest rate on record, which means accumulation of stock. In the newspapers there is some talk about curtailment of production, but why should there be any such action? Almost all of the big producers can make a lot of money at the present price, or less, and after all their business is to produce copper, rather than to speculate in futures. The present price for copper is not much below the average for the last 10 years; nor is it yet close to the average cost of production. The talk about increased cost of production, respecting which we used to hear a great deal, was chiefly nonsense. Like the iron and steel market, the copper market can, and probably will, go the natural way to stimulate consumption.

Notes about Spelter

On Jan. 9 we reported the organization of the European Zinc Syndicate. The British papers began to hear about it around Feb. 1; the American papers, daily and otherwise, are just awaking to the fact, this week.

There has been a big drop in the price of zinc ore at Joplin. According to our correspondent at that place, the miners lay it to the decision admitting calamine free of duty, while the smelters attribute it to the tariff agitation, which keeps consumers from contracting ahead for spelter. It is strange that no one thinks about the depression in business that still exists.

We hope to be able next week to report our final figures for spelter production in 1908. Probably they will differ from the preliminary figures that we published Jan. 9 by only a few hundred tons. Our estimate of the stock on hand at the end of the year, published at that time, was based on reports of the smelters for Dec. 15. Between that time and Dec. 31 there was apparently a reduction of stock in first hands, and our revised figure for that item is likely to be smaller than previously reported.

However, with respect to the unsold stock there appears to be a peculiar condition. According to our preliminary statistics, the deliveries into consumption in 1907 were 222,494 tons; in 1908 they were 210,868 tons, a comparatively slight falling

off. These figures are computed by difference in the usual manner.

As our readers are well aware, later in the year we collect statistics as to consumption from the consumers themselves. Our reports as to spelter are still incomplete, but we feel that our readers will be interested to know that the same concerns which reported a consumption of 100,657 tons of spelter in 1907, for 1908 report only 75,037 tons. Recognizing the present incompleteness of the statistics, we shall not attempt to draw any inferences. We add only that the statistics received up to date represent chiefly the galvanizing industry.

The Question of Prices

A "New England manufacturer of copper wire" is represented as saying the following: "Now we are asked to buy copper at 13½¢, but nothing is said about the copper we purchased at 14½¢, nor the advantage over us that has the wire manufacturer who did not take the former advice of the copper people and now buys at 13½¢. Copper is controlled to a greater extent than any other commodity, i.e., half a dozen interests control the bulk of the output, and yet the consumer is assured of less stability than in almost any other commodity. The consumers do not care whether the price is 13, 14, 15, or 16¢. If the copper producers would only get together and maintain prices as do the steel people, it would be of great advantage to all concerned."

This shows simply how slow is the light in dawning upon some minds. The consumers do care what is the price of copper; the manufacturers, who are often confused with the consumers, may not care; indeed, if they could be assured of stability, they might prefer a high price to a low price. But we have not yet come to the point where middlemen are going to be protected against fluctuations in price.

Just as some producers sell to better advantage than others, so do some manufacturers buy. If producers, merchants and manufacturers must be guaranteed against bad judgment, why not have prices fixed by Congress, or an international tribunal? Of course, they should be established at figures affording a "reasonable" profit to the producers, middlemen and manufacturers, by which is to be understood just stopping short of breaking the consumer's back.

Apropos of the haunting fear among manufacturers that if one buys at 13¼¢, today another may cover his requirements at 12¼¢, next month, it was misleading news from such quarters in the spring and summer of 1907 that put some of the producers so much astray. In the spring of that year most of the manufacturers covered their requirements up to the end of June. Long before that time the slackening in business was apparent to them, but they tried to keep that a secret until their 25¢ copper was consumed, and to some extent succeeded.

It is not the fluctuating market that is vicious, but rather the system of contracting far ahead. There is gambling in a manufacturing business just as there is in Wall Street and Capel Court. Some producers gamble in selling their output and some manufacturers in buying their supplies. But after all there are few who beat those who buy and sell regularly at the market, and the conservative interests, either way, do not need to worry.

Publicity by Mining and Metallurgical Companies

A few weeks ago in speaking of the rights of stockholders to prompt information respecting their companies, and the general superiority of British companies, as compared to American in this respect, we remarked that sooner or later we shall come to the same practice in this country. In this connection, it is particularly interesting to remark that the Guggenheims have just announced that the copper mining companies in which they are interested—the Utah Copper Company, Nevada Consolidated, and Cumberland-Ely—will hereafter make quarterly reports. On top of this, everyone was surprised this week by the appearance of a report by the American Smelting and Refining Company, covering the first six months of its current fiscal year, and we are given to understand that in the future that company will make semi-annual reports. This is high commendable. It is only to be regretted that the reports are not of more communicative character. However, we shall no doubt, in the course of time, find improvement even in that respect.

The copper companies, whose fiscal year corresponds with the calendar (it is a pity that this is not so in all cases) are now beginning to make their reports for 1908. One of the first that we have received is

the report of the First National Copper Company (Balaklala). This is an admirable presentation, communicating all of the information that the stockholder needs to know, besides a great deal of important information that is of technical interest and value. The directors of this company are to be congratulated upon their frankness.

So the march of improvement goes on. We have no doubt that we shall see the day, perhaps in the not very distant future, when the Amalgamated Copper Company will make an annual report, perhaps even a quarterly report, that will be as satisfying as those of the U. S. Steel Corporation.

The Conservation of Resources

The President, in a message to Congress, Jan. 22, on the conservation of resources makes the following remarks respecting the mineral industry:

1. "The accompanying reports show that the consumption of nearly all of our mineral products is increasing more rapidly than our population. Our mineral waste is about one-sixth of our product, or nearly \$1,000,000 for each working day in the year. The loss of structural materials through fire is another million a day. The loss of life in the mines is appalling. The larger part of these losses of life and property can be avoided.

2. "Our mineral resources are limited in quantity and cannot be increased or reproduced. With the rapidly increasing rate of consumption the supply will be exhausted, while yet the nation is in its infancy, unless better methods are devised or substitutes are found. Further investigation is urgently needed in order to improve methods and to develop and apply substitutes.

3. "It is of the utmost importance that a Bureau of Mines be established in accordance with the pending bill to reduce the loss of life in mines and the waste of mineral resources, and to investigate the methods and substitutes for prolonging the duration of our mineral supplies."

It is evidently destined that the Americans of the beginning of the Twentieth century are to be recorded in history as a wasteful people. Far be it from the idea of the JOURNAL to deny that charge or to minimize the usefulness of the present propaganda. We are a wasteful

people; shamefully wasteful. In spite of that the nation is wealthy because of the bounty of nature. But how much more wealthy would it be if Americans should exercise the economy of the French!

However, as the JOURNAL has previously pointed out our wastes are rather of consumption than of production, and it seems as if the President and the Conservation Commission are putting stress upon the wrong side of the balance. We don't mind being called extravagant in our living; indeed we may feel a little proud that we are more liberal in our views than the thrifty French. But when it comes to production mining, manufacturing, etc.—which is *business*, wherein we think we show our heels to every other nation on earth (except when the matter of revising the tariff is before us), we don't like to be called wasteful, because we are not so (except for some oversights that are corrected as we learn how).

Let us look at some of the wastes that we have committed; perhaps are still committing. Possibly the most criminal was the shocking sacrifice of the natural gas of the Eastern States. That was due largely to ignorance. When natural gas was discovered in Kansas we knew more about it and the resources there were well conserved from the outset. However, there are still districts, as in the Caddo field of Louisiana, where there is scandalous waste. Another great loss of potential value is experienced in the manufacture of coke in beehive ovens. This has been recognized for many years. Much progress in the installation of improved coke ovens has been made, but our industrial requirements have not yet developed to such an extent as to take care of all the by-products that it is possible to recover, and capital has not yet seen its way clear to utilize the waste heat at central points for the generation of power to be distributed electrically. But a modified beehive oven permitting utilization of the waste heat is already coming extensively into use. We have wasted much low grade ore as stope-filling and by careless mixture in tailings piles which later improvements would have made valuable; but we are not now generally guilty of that sort of waste. It is true that we still waste immense amounts of coal in the destruction of the seams that cannot now be mined profitably, but this is chiefly a consequence of capitaliza-

tion, which requires the immediate production of coal that can be won, and there does not seem to be any way to prevent such waste except by State confiscation of property, which, of course, cannot be considered.

We do not feel quite sure that the preventable waste in coal, lead, zinc, copper, gold and silver mining amounts to approximately \$1,000,000 per day, as has been estimated by the National Conservation Commission. However, the President, of course, could do nothing but accept the report of that commission. The figure stated for the loss of structural material through fire also appears somewhat high, although there is no question as to the enormity of the loss experienced in this way, which loss is to a large extent preventable. We recognize also the money value of the appalling loss of life in mining.

As to the second section of the President's remarks, we point out that the mining industry is constantly investigating and seeking to improve methods and to develop and apply substitutes for the simple economical reason that more money can be so made than by standing still. Comparison between mining and metallurgical results of today and those of 10 years ago shows that immense progress has been made. The Conservation Commission and the President do not appear to recognize this. In paragraph 3 the President urges the establishment of a bureau of mines to reduce the loss of life in mines and the waste of mineral resources. We have not the same confidence that a bureau of mines can do anything very useful in either respect.

Steel Production in 1908

The decline in bessemer steel production in the United States in 1908 was much greater than that in pig iron. The complete figures collected by the American Iron and Steel Association give the total make of bessemer ingots and castings in 1908 at 6,110,065 long tons, a decrease from 1907 of 5,550,794 tons, or 47.5 per cent. The output was, in fact, the smallest reported for 10 years, being less than that of any year since 1897. A large reduction was expected, but the decrease extended further than in pig iron and other branches of the trade. A considerable part was, of course, the result of the general

depression; but another large part was also due to the substitution of open-hearth for converter steel. This is confirmed by a study of the detailed statistics. Thus the largest proportional loss is found in Pennsylvania, and a very considerable part of this resulted from the substitution of open-hearth furnaces for converters at the Carnegie and some other works.

While the figures for open-hearth steel are not yet available, there is no doubt that the decrease was very much less than in bessemer, and that the production of open-hearth metal constituted a much greater proportion of the total than in any previous year. By far the greater part of the open-hearth make is of basic steel. For four years prior to 1908 the proportion of basic pig iron to open-hearth steel was 1 to 1.9; estimating on this basis the production of open-hearth steel in 1908 was approximately 7,600,000 tons, 1,500,000 tons more than that of bessemer. Last year the prediction was made that the relative positions of the two classes of steel would alter in 1908; but quite so sharp a change was not anticipated.

Heretofore rail production has absorbed a large proportion of the bessemer steel made, but that condition also seems to be changing. The total make of rails in 1908 was 1,921,071 tons, a decrease of 47 per cent. from 1907, and the smallest production since 1897; a result largely due to financial conditions and difficulty experienced by the railroads in providing money for purchases, but in part also to the controversy over the quality of rails. The chief point in the report for the year is that while the decrease in the make of bessemer rails was 60 per cent., there was an increase of 125 per cent. in open-hearth rails. The proportion of the latter to the total make rose from 7 per cent. in 1907 to 29.5 in 1908. It is true that this increased proportion is on a very light production and had some special causes to favor it. On the other hand, the great rail mills at Gary will begin to produce in 1909, and they will use open-hearth steel exclusively.

The open-hearth furnace is clearly the coming steel maker, and its position is assured by the ability it possesses of utilizing pig iron made from varieties of ore which are not adapted to the acid bessemer process. The converter has seen its best days, though a large quantity of bessemer steel will be made for a long time to come.

Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Some Facts and Corrections Regarding the Diamond Region of Arkansas

The article on an Arkansas diamond mine by John T. Fuller in the JOURNAL of Jan. 16, page 152, contains a reference to me that may be taken as an excuse for correcting some statements in that particular article, and for giving some facts that may have some historical interest in connection with the discovery of diamonds in Arkansas.

We Americans are so fond of our little joke that whenever any good thing is found or developed we must find the man who missed the chance of his life, or who, in one way or another, failed to appreciate the situation. Sometimes this foolish man had the opportunity to buy the land where Chicago now stands for \$10; sometimes he owned the land where a great mine is now located, and sold it for a song; sometimes he declared that something could not be done and a few years later it was done. If it can be shown that the "one-gallus" man succeeds in any enterprise when the chemist, consulting engineer, or the geologist declares it to be impossible, then the conditions are all fulfilled, and everybody is happy—except the fellow who missed it, and often enough he is a purely hypothetical character. If it can be shown that several persons overlooked a good thing, it only causes the wisdom and longheadedness of the successful man to stand out in bolder relief.

When diamonds were found in Arkansas a few years ago this desire to bring into relief the picturesque features of the discovery naturally caused people to look about for the man who had missed it. Mr. Fuller, in the article referred to, makes it appear that I am "it" in this case. He says that "no report of any accuracy was made until 1890, when the region, including the volcanic area, was mapped and reported on by John C. Branner, who at that time was State geologist. In this report Branner mentions that the rock resembled closely the diamond-bearing rocks of South Africa, but scouts the idea of its containing diamonds, due to the absence of any bituminous shales surrounding the 'pipe' or crater." The last sentence is italicized in order to call attention to two questionable statements.

THE ORIGINAL DESCRIPTION

The article by Branner and Brackett

describing the exposure of peridotite in which diamonds occur was first published in the *American Journal of Science* July, 1889, Vol. XXXVIII, pp. 50-59; the article was partly reproduced in Vol. II of the annual report of the Geological Survey of Arkansas for 1890, pp. 378-391. On page 54 of the first article, and on page 389 of the second one is the following sentence: "Inasmuch as it has been suggested that the South African diamonds may have been generated by the metamorphism of the carbon in the carbonaceous shales penetrated by the peridotite, I should add that no such phenomenon is suggested by observations at this locality, or upon these rocks." In other words no diamonds were found in the rocks.

This is all that was said in regard to diamonds, and this much was said deliberately, and it is all there was any warrant for saying at the time. There is not a word in the original article to show that the writer of it scouted the idea of diamonds occurring there, nor is there a word in explanation of their assumed absence. The existence of large quantities of shales in the rocks through which the peridotites pass was perfectly well known, and these shales are spoken of more than once in the article. On page 51 in the *American Journal of Science* article a small dike is mentioned as containing "a vast quantity of fragments of paleozoic sandstone and shale." On page 52 mention is made of the sedimentary beds that lie to the north of this exposure and through which the dike rock must pass. It is stated that "they are made up of alternations of sandstones and shales, and are highly flexed, the axes of the folds varying but little from due east and west." Again at page 53, second line from the bottom, reference is made to the shale inclusions in this dike. In view of the fact that Mr. Fuller's article reproduces my geologic map (without credit) and repeats most of my geology (likewise without credit), it seems reasonable to have expected him to find some mention of the shales.

WHY THE DISCOVERY WAS NOT PREDICTED

It may fairly be asked, however, why the diamonds were not found, or why it was not predicted that they would be found, since it is evident from the sentence quoted that the idea of diamonds had occurred to the author of the article. Aside from the fact that prediction is no part of a State geologist's duties, there

were good reasons for the guarded statement as will appear.

The older geologists of this country will remember that in 1885 Dr. J. S. Diller published a short article in *Science* (V, 65) announcing the discovery of peridotite in Elliott county, Kentucky. In 1886 H. C. Lewis, in speaking of the origin of diamonds, referred to this case and says that it "suggests interesting possibilities" (*Science*, Vol. VIII, p. 347), and Dr. Diller in Vol. VIII, p. 392 says that he considers it "rather improbable that diamonds will be discovered at the locality in question." In spite of Dr. Diller's conservative views the people of the State of Kentucky, under the leadership of the newspapers, went wild on the subject of Kentucky diamonds. The excitement was not confined to the region of the peridotites, or even to Elliott county, but spread into every nook and corner of the State. It was soon pretty generally believed that all one had to do to find diamonds was to cross the line into Kentucky. The amount of time, labor, and money squandered in this wild scramble no one knows. Companies were formed both in and out of the State to buy up diamond lands. I, being acquainted with the geology of the diamond regions of Brazil, was kept busy for months in trying to cool the ardor of people over-anxious to get hold of so-called diamond lands in Kentucky. One company sent me to examine and report upon the chert gravels along the lower part of the Ohio river, on the Kentucky side, with a view to ascertaining their diamond contents. The same gravels on the Indiana and Illinois side were not to be examined.

Shortly afterward, in 1887 I was appointed State geologist of Arkansas. When I went to that State I found in full swing one of the wildest and most uncontrollable mining excitements that ever broke forth in any part of this country. In the region west of Little Rock, and especially in Garland and Montgomery counties, many of the people had actually abandoned their farms to stake off claims and to mine gold, and nearly everybody was buying and selling mine shares and was on the verge of getting suddenly and enormously rich. The official records at Little Rock show that the mining companies organized under the laws of Arkansas alone for working these gold and silver mines were capitalized at more than \$113,000,000. Some account of the affair is published in *The Arkansas Gazette* of Aug. 11, 1888 and in the JOURNAL

of Aug. 18, 1888, p. 128; of Sept. 1, p. 168; Sept. 8, p. 189; Oct. 6, p. 278; and of Oct. 20, 1888, pp. 325-327. Anyone who will take the trouble to read the articles referred to will see that the people of Arkansas were not at that time in a frame of mind to have diamond deposits suggested to them. Whatever the State geologist might think of the possibilities of the peridotite, under the circumstances he was certainly not warranted in starting a fresh excitement, especially when there was nothing more than a theory to base it upon. But so far as the theory was concerned, I was quite as well acquainted with it then as I am now. The peridotite was not only recognized as the kind of rock in which diamonds occur in South Africa, but I spent many hours on my hands and knees looking for diamonds in the gullies and over the bare surfaces of the decomposed rocks. But like many others who have gone there since the discovery, I found no diamonds, and as my examination was not in any sense a systematic or thorough one, it only remained for me to refer to the diamond question in a guarded manner.

PRE-DISCOVERY STATEMENTS

After the excitement in Arkansas had subsided I made the statement on various occasions that it was possible that there might be diamonds in this peridotite area. How many persons may have heard this statement I do not know, but the following extract from a letter shows that one man at least remembered it. Before I knew of the discovery of diamonds in Arkansas I received a letter from an Arkansas friend, Col. Henry T. Buie, who wrote from Chicago under date of Sept. 27, 1906, as follows: "I see from the Arkansas papers that diamonds have recently been found in Pike county not far to the southeast of Hot Springs. When you were at Buffalo, (Marion county, Ark.) I remember you told me there was a geological formation in that section of the State that would justify the presence of diamonds, but it does not seem to me that you spoke of Pike county, and it must have been some other locality." My letter book shows that I replied to Col. Buie Oct. 2, 1906, as follows. "Your letter gives the first intimation I have had of the discovery, and you do not mention the locality. The place I referred to in the conversation you mention is on the Little Missouri river about 13½ to 2 miles below (down stream from) Murfreesboro in Pike county"—in other words, the peridotite area in which the diamonds occur.

It may be worth adding that the statement made by Mr. Fuller in the foot-note on page 152 of his article to the effect that "diamonds have never been found in South America in the true matrix," is not correct. Certain washings near Diamantina in the state of Minas Geraes took their material entirely from itacolumite decomposed in place. This locality I have

visited and I make this statement from personal observations. The late James E. Mills stated to me that he had seen a diamond in place in the itacolumite. Recently Prof. O. A. Derby, the director of the Geological Survey of Brazil, has seen a diamond from Bahia in the original quartzite.

JOHN C. BRANNER.

Stanford University, Cal., Jan. 26, 1909.

The Gordon Drill

In a recent issue of a technical journal a Johannesburg correspondent mentions the failure of the Gordon drill, and states that it was due almost solely to the failure of the hammer block, but that the ratchet teeth caused some little trouble and expense by breaking. The correspondent goes on to say that the hammer block would swell, i.e., upset and stick in the barrel of the drill. If the piece was tempered hard enough to prevent upsetting it would break, and in doing so would cause serious injury to the machine.

The makers of another drill, which I shall refer to later on as the X drill, had the same trouble with their hammer blocks that the Gordon drill is said to have had. The makers of the X drill overcame the trouble fully by making a slight change

in the hammer block and the use of vanadium steel. The accompanying sketch shows the change made in the hammer block.

I found it to be impossible to get the temper to the center of the solid block, even when made of vanadium steel, but by making the simple change shown, absolutely satisfactory results were obtained. No matter what shape the blocks were made, with steel, other than vanadium steel, they would either upset or go to pieces. So far as the Gordon ratchets are concerned I presume vanadium steel would do the work without breaking.

The makers of the X drill have claimed a very high efficiency for their drill, *with 100 lb. air pressure at the drill*. Now, under actual working conditions, it has been found impossible to make a drill steel that will stand when 100 lb. pressure is used at the drill. In every instance the drills snap off at or near the shank, say within 3 or 4 in. of it. The cutting edges stand well.

The Crucible Steel Company of America made a special drill steel for the manufacturers, containing 0.10 per cent. vanadium. This steel proved to be about eight times as durable as the ordinary

drill steel, but it cost 15c., while the ordinary steel costs 8c. per lb. Anyway, it was found to be more economical to operate the drill under 80 lb. air pressure, for under higher pressure the vanadium steel could not be depended upon. It would break in the same way as the ordinary steel, but not so frequently.

At the present time the capacity of the hammer drill is the ability of the drill steel to withstand the blows of the hammer. There is little to choose between the several makes of hammer drills so far as their drilling efficiency is concerned.

Denver, Colo., Jan. 4, 1909.

W.

The Turquoise Mining District, Arizona

In my short article on the Turquoise district, which appeared in the JOURNAL of Jan. 23, 1909, p. 213, I note an error, possibly my own, but a notable one. In mentioning ores of the Leadville Mining Company, the article as published reads "3 per cent. to 5 per cent. lead;" this should be "copper." This gives an entirely erroneous idea of the whole camp, as I find that copper is not mentioned again in the article. All of the chief mines of the camp are copper strictly.

JAMES M. PLATT,

Superintendent Guadalupe Mine
Zacualpan, State of Mexico, Mex.,
Feb. 2, 1909.

Steel Ore-Pass

A steel ore-pass, invented by D. P. Mitchell, general manager in Australia for Bowick, Morring & Co., is now largely adopted by that company in the South Blocks mine at Broken Hill. This ore-pass is made up of cylindrical sections of boiler iron having a collar at one end, so that one fits into the other below, the pass being built up as stopping progresses. The top of the chute is fitted with a funnel in which is placed a grizzly so that boulders must be broken before they can enter the ore-pass. The advantages of an iron pass are that there is no wearing out before the stope is completed (therefore no dangerous and expensive repairing to be done as in the case of a cribbed ore-pass), and that there is no wood to wear away and get into the ore giving trouble in the mill.

Although India imported more than \$4,500,000 worth of copper in 1907 none of the many known deposits of the country was worked to any extent (Geological Survey of India). Extensive prospecting of the copper deposits is, however, now in progress. The manufacture of sulphuric acid as a smelter by-product will also give a new lease of life to many of the minor industries.

The H. C. Frick Coke Company

The statement was published last week on the strength of a Pittsburgh despatch that "the Frick Coke Company has abandoned work which was to cost \$3,700,000 on 1700 additional coke ovens at Uniontown, Penn., and will substitute for the proposed beehive ovens an enormous by-product coke plant at Gary, Ind." This is pronounced incorrect by authority. No coke ovens in the Connellsville region have been abandoned, and though work on a number, which had been planned, has been suspended owing to the dullness of the past year, it is intended to proceed with the plans as soon as conditions warrant. The only by-product coke plant at Gary is a small one, intended chiefly for testing purposes, on Indiana, Illinois and other coals which may be offered. The Frick company has some land at Indiana Harbor, but it was acquired only to provide for contingencies which may arise in the future. For the present, at any rate, it appears more advantageous to make coke at the mines and to ship that coke, than to carry raw coal nearly 500 miles to the ovens.

Goldfield Consolidated Mines Company

The following items are taken from the annual report of the Goldfield Consolidated Mines Company for the year ending Oct. 31, 1908. The company now controls and operates claims having an acreage of 380.627 acres besides holding a 25 per cent. interest in the C. O. D. Consolidated; by agreement it is to receive one-half of all ore found in the Vinegorone and Poleverde claims of the Jumbo Extension Mining Company in veins apexing on the Consolidated ground.

SURFACE IMPROVEMENTS

On the old Jumbo property a central compressor plant, electric distributing station and machine shop have been installed. The two Nordberg two-stage air compressors, each belt driven from a 200-h.p. electric motor, have a joint capacity sufficient to operate two hoists and all the necessary machine drills. At the Mohawk shaft a hoisting plant capable of being operated by either steam or compressed air, capable of raising about 500 tons of ore per day has been installed. The electric hoist formerly at the Mohawk shaft has been moved to the Combination shaft, where a second hoisting compartment has been completed to the bottom of the shaft. This hoist has a capacity of about 300 tons per day. A standard-gage railway about two miles in length has been built with branches to connect all the working shafts of the property with the new mill and all the railroads entering Goldfield. The rail-

road is equipped with a locomotive, six steel hopper cars of 50 tons capacity each and one flat car. Reservoir facilities consist of 10 tanks placed conveniently to the mill, having a capacity of 1,000,000 gallons or sufficient supply for 10 days, in case of stoppage of the water supply. A new 100-stamp mill with an estimated capacity of 600 tons per day has been built.

UNDERGROUND WORK

At present the Mohawk, Combination, Clermont and Red Top shafts are in commission. During the present fiscal year development work has been carried on continuously on the Mohawk, though little ore was mined owing to inadequate milling facilities. On the 250 level old workings were repaired and new drifts driven under the Hayes-Monette, Frances-Mohawk and other lease stopes, thus making them accessible from the main shaft. On the 600-ft. level, the lowest of the mine, an orebody 20 ft. wide has been crosscut and connected by raises with the same orebody on the 450-ft. level. A crosscut from the 600-ft. level will soon connect with the Clermont shaft.

The Combination workings have been connected with the Mohawk on the 280-ft. and 380-ft. levels; with the Reilly workings on four levels and very good ore is exposed to the bottom, 380 ft. In the central part of the property a greater amount of ore than was suspected has been opened up. The 130-ft. and 230-ft. levels now connect with the January and good ore has been developed in the continuation of the January vein on Combination ground. Very recently rich ore has been discovered on the 230-ft. level, north and west of the older workings. A drift on this vein shows an orebody 6 ft. in width and already exposed 60 ft. in length which averages higher than \$100 per ton.

Recent development work from the Red Top shaft has traced ore on the 260-ft. level, 50 ft. north of the older workings, and a very promising orebody has been followed more than 150 ft. south on the Lucky Boy claim, in territory where no ore was heretofore supposed to exist. In the Mushett lease a small ore shoot has been proved to extend to a depth of 480 ft. below the surface, and about 130 ft. below the deepest level of the Red Top. On the Jumbo, the Clermont shaft has reached a depth of 850 ft. and very recently a strong ledge which shows very promising values has been cut.

During the past year 32 leases operated at various times on the property performing in all 20,463 ft. of underground exploratory work, producing 25,539 tons of ore.

MINING STATISTICS

In all 17,460 ft. of development work was performed on company account at an average cost of \$17.60 per foot and 20,463 ft. by leasers at no cost to the company,

making a total of 37,923 ft. of exploration work at \$8.10 per foot. There was hoisted on company account from stopes 25,374 tons; from development work 19,562 tons, total 44,936 tons. Of this ore there were milled

	Tons.	Gross Value.	Average per Ton.
Milled	29,180	\$1,164,246	\$39.89
Shipped	3,575	195,593	54.71
Total by Co.	32,755	\$1,359,839	\$41.51
By lessees	25,540	945,196	37.01
Total	58,295	\$2,305,035	\$39.55

Below is a statement of mining and milling costs at the Combination, the only property from which ore has been continuously mined during the year, including every item properly chargeable to the operation, maintenance and administration of that property.

	Tons.	Average per Ton.	Total.
MINING:			
Ore production	22,831	\$1.51	\$34,461
Development			
6026 ft. @			
\$16.34	11,891	9.51	113,136
General expense			22,223
Total	34,722	\$4.89	\$169,820
MILLING:			
Milling	28,462	\$5.60	\$159,367
General expense		0.78	22,224
Total		\$6.38	\$181,591
TOTAL COST:			
Ore mined and			
milled	28,462	\$11.27	\$320,765
Ore broken and			
milled	16,998	2.40	40,722
Total	45,460	\$7.95	\$361,487

Mining and milling costs for the previous fiscal year were as follows: Mining, \$6.147; milling, \$7.142; total, \$13.289. It is estimated that the mining and milling costs on ore treated at the new mill will be reduced to \$6 per ton, including transportation and general expense, for the ensuing fiscal year.

The item of general expense for the past year is necessarily high by reason of the small production and the large items of expense superinduced by strike conditions early in the year.

Refunds of Duties on Coal

SPECIAL CORRESPONDENCE

The Senate has just passed and sent to the President a bill passed by the House on May 12 last providing, among other features, for refunding duties on anthracite coal imported into the United States from Oct. 6, 1902, to Jan. 15, 1903. It will shortly be signed and become a law.

Success is responsible for the following: Professor (at chemistry examination)—Under what combination is gold released most quickly? Student—Marriage.

NEW ZEALAND. PAPERS AND REPORTS RELATING TO MINERALS AND MINING. Pp. 196. illustrated. 8½x13 in.; board

covers. Wellington, 1908: John Mackay, Government Printer.

Contents: Statement by the minister of mines. Report on the goldfields. Report on coal mines. State coal mines. Features of special interest and electrical installations at mines in New South Wales and Victoria.

METALLIC ALLOYS: THEIR STRUCTURE AND CONSTITUTION. By G. H. Gulliver. Pp. 254. illustrated. 5½x8 in.; cloth, \$2. London, 1908: Charles Griffin & Co., Ltd.; Philadelphia, J. P. Lippincott Company.

Contents: Methods of investigation. The solution theory, and the chemical equilibrium of mixed substances. Binary alloys in which no definite chemical compounds are formed. Binary alloys which show evidence of the formation of definite chemical compounds. Equilibrium conditions in metallic mixtures. The bronzes, the brasses and the steels. Alloys of more than two metals.

FOUNDRY PRACTICE. Third Edition. Revised. By James M. Tate and Melvin O. Stone. Pp. 234; illustrated. 5x7½ in.; cloth, \$2. New York, 1909: John Wiley & Sons, London, Chapman & Hall, Ltd.

Contents: Green sand molding. Dry sand molding. Molding sand, molder's tools, molding machines and equipment. Cores, core boxes, core machines and dry-ovens. Cupolas, blowers, and melting furnaces for iron. Chilled castings. Malleable castings. Cleaning castings. Compressed air for foundry purposes. Steel castings. Brass founding. Cast-iron alloys. Glossary of foundry terms.

THE MECHANICAL APPLIANCES OF THE CHEMICAL AND METALLURGICAL INDUSTRIES. By Oskar Nagel. Pp. 307. illustrated. 6x9½ in.; cloth, \$2. New York, 1908: Published by the author.

Contents: General. Steam and water power. Gas power. Electric power. Transportation of Solids. Transportation of liquids. Transportation of gases. Grinding. Mixing machines. Firing and furnaces. Separating. Purification of gases. Evaporation, distilling and condensing. Drying appliances. Measurement of temperature. The works chemist as engineer.

This is a useful book. It is of descriptive character, rather than analytical and critical.

WHO'S WHO IN MINING AND METALLURGY. Founded by George Safford. Pp. 104. 5½x8¼ in.; leather, \$6. London, 1908: The Mining Journal.

This is a collection of brief biographical sketches of mining geologists and mining and metallurgical engineers. Although published in London, we find that American engineers are quite as well represented as are the British. The work, which is of undeniable usefulness, consequently has an international character

We hope that some day its scope may be extended so as to be completely international and take in the engineers of France, Germany, and other countries. The book, which is very good for a first attempt, has some defects which will doubtless be corrected in subsequent editions. The chief of these are (1) omission of some of the most prominent engineers, and (2) an absence of editing of the biographical sketches, of course furnished personally, which sometimes leaves them to recite insignificant appointments, such as "delegate to the American Mining Congress."

REPORT ON THE MINING AND METALLURGICAL INDUSTRIES OF CANADA, 1907-8. Pp. 972; illustrated. 6½x10 in.; paper, \$1. Ottawa, 1908: Government Printing Bureau.

This volume, giving fuller information concerning the mining and metallurgical industries of Canada than any hitherto published, is based upon data furnished by a special staff of investigators, with a view to meet the increasing demand for accurate and authoritative details as to these important interests. It is arranged by provinces and embraces reports and in many cases detailed descriptions of all producing mines and those approaching the productive stage and of metallurgical plants in active operation. Its value is materially enhanced by the illustrations, giving representations of the equipment and methods of operation of leading mines and industrial plants. Specific descriptions of known mineral deposits of value are also given, with maps of the different provinces showing their location. Among the prominent geologists and engineers, whose knowledge of particular localities renders their contributions specially instructive are Dr. R. W. Broek, director of the Canadian Geological Survey, Charles Cammell, Osmond E. Le Roy, J. C. Gwillim, S. S. Fowler, Joseph G. S. Hudson and H. Mortimer Lamb. The report embodies a large amount of historical and statistical information in regard to all branches of the mining and allied industries. Not the least valuable feature is the list of mineowners and companies together with the capitalization and the officers of each company. The index gives some 1500 names of mineowners and corporations. As a matter of arrangement it might have been better had these details, instead of being given in connection with each enterprise throughout the volume, been embodied in a separate section, as owing to the frequent changes in company organization these particulars will be inaccurate and misleading before long, whereas a separate list could be easily corrected for the next annual report and the necessary changes made from time to time. The book will be much appreciated by investors, mining men and others requiring accurate information as to Canadian mining undertakings and mineral resources.

Questions and Answers

Inquiries for information are answered in this department as promptly as possible, but more or less delay is often unavoidable. Many inquiries involve a good deal of investigation and these can be answered only when the general interest in the subject is conceived to justify the expenditure of the time required. Correspondents should refrain from asking for advice that ought to be obtained by professional consultation with an engineer. We will not answer questions pertaining to the value of specific mining enterprises. Inquiries should be framed concisely.

COLOMBIA AS A MINING COUNTRY

Is it true that Colombia at the present time offers the best opportunities for new mining enterprises?

R. M. S.

Comparisons are always odious. Colombia undoubtedly is a promising mining country. We should hesitate to say that it offers the best prospects. A good account of the mineral resources of Colombia is to be found in the bulletin of the American Institute of Mining Engineers, September, 1908.

BRASS VS. IRON FOR SAFETY-LAMP GAUZE.

Will copper or brass wire offer the same degree of safety on the safety-lamp gauze as does iron?

MINER.

Iron gauzes in safety lamps are cheaper than those made of brass; for this reason the former are more generally used. The brass gauze, however, has its particular advocates who advise its use in wet mines where dampness would be likely to corrode iron. There are also many miners who claim that the brass gauze is safer than iron. Safety-lamp manufacturers will supply either brass or iron gauzes according to the wish of the purchaser.

STANDARD COPPER

Please explain for the benefit of the readers of the JOURNAL what is meant by "Standard" copper, as dealt in on the London exchange and quoted in the JOURNAL. One Western copper producer who was once associated with a London firm is under the impression that "Standard" copper is now a fictitious commodity, the term having originated before the days of electrolytic refining. It is his understanding that whenever the holder of a warrant calls for delivery of the metal, the seller is entitled to deliver electrolytic copper and to demand a premium at the rate of £1 per 2240 lb., but he is not sure of this. I have asked the same question of other men engaged in producing and selling copper, and all confess ignorance on the subject.

G. W. R.

The term "Standard" copper is a substitute for the former "good merchantable brands," or "G. M. B.'s" and is the standard basis of trading on the London Metal Exchange. The committee of the latter prescribes an official list of the brands of copper that are good delivery under the

rules and regulations. Sellers have the option to deliver each 25 tons either in:

Class A—Refined copper not less than 99 per cent. and below 99.30 per cent., at contract prices;

Class B—Refined copper assaying not less than 99.30 per cent. and below 99.80 per cent., and tough cake with certificate of quality as per Rule 1, at 10s. per ton over contract price;

Class C—Refined copper assaying not less than 99.80 per cent., at £1 per ton over contract price;

Class D—Rough copper subject to a rebate of £1 10s. per ton from contract price (see also Rule 1).

The rules referred to appear in the standard form of contract and are as follows:

Rule 1. All warrants for refined copper (other than tough cake) shall be accompanied by a certificate stating the produce which shall in no case be less than 99 per cent. All warrants for tough cake shall be accompanied by a certificate that the copper is of good merchantable quality, and fit for rolling. The cakes shall not weigh less than 1 cwt., or more than 2 cwt., each. For rough copper the standard of produce shall be 97 per cent., but no excess shall be paid for. A pro rata allowance based on the settlement price shall be made for deficient produces below 97 per cent., down to and including 96 per cent. and a double pro rata allowance on the same basis for deficient produces below 96 per cent., down to and including 94 per cent. Produces below 94 per cent. shall not be a valid tender. All certificates for rough copper shall state that the quality has been passed by the assayers as good merchantable. Warrants for rough copper warehoused previous to October 1, 1904, with certificates of assay by the Cornish method shall constitute a valid tender under this contract; the Cornish assay to be translated into the wet assay by adding one unit.

Rule 2. Sampling and Testing. The sampling of refined copper shall be effected at the public warehouse by drilling one piece for every five tons, in the case of tough cake one piece in every five tons being taken for testing as prescribed, and of rough copper by drilling sufficient pieces to constitute not less than 10 per cent. of the weight of the parcel, each brand to be sampled and assayed or tested separately. In the case of refined copper one sample only shall be drawn from the drillings and the produce determined by a public assayer, but for rough copper three samples shall be taken from the drillings, and one sent to each of two public assayers, who shall agree as to the produce, and if they are unable to agree, the third sample shall be sent to a third public assayer chosen by the other two whose report shall be final and binding. If the sale be made prior to sampling, buyers shall have written notice of seller's in-

tention to sample not later than 3 p.m. on the day previous to the day of sampling, specifying the place and hour at which sampling will commence and whereat buyers shall be at liberty to be present or to be represented. The entire cost of sampling and assaying, or testing, shall be borne by the sellers. The assaying, both of refined and rough copper, shall in all cases be done by the wet method.

Rule 3. Warrants tendered shall be those of a public warehouse in London, Liverpool, Birkenhead, Swansea, Birmingham or Newcastle-on-Tyne, the name of which shall appear in the official list of the committee. The copper shall have been weighed in drafts of 10 cwt. each, except Chile bars, which shall have been weighed in drafts of five bars each. Standard copper shall be, as far as possible, in warrants of 25 tons each, and each parcel of 25 tons, whether rough or refined, shall be of the same form and class, and shall be in one of the above-named places; and if the warrants be tendered against a contract for a multiple of 25 tons they shall be capable of subdivision into parcels of 25 tons each.

Rule 4. Certificates of assay or quality, in the form settled by the committee, shall be attached to all warrants deliverable under this contract, and the certificates shall be those only of experts, assayers, or analysts, approved of by the committee. Warrants for Standard copper shall be a valid tender, even without certificates of assay or quality, but buyers need only pay a sum on account, say, within 3 per cent. of the invoice value, and the balance on production of the certificates, which must be delivered within one month from the date of the warrant. The payment of buyers of a sum on account shall not invalidate their right of rejection should the certificate subsequently prove that the copper is not a valid tender under the preceding rules.

Rule 5. Should any Standard copper, subsequently to tendering, prove to be of such quality or produce as not to constitute a valid tender under these rules, buyers shall be entitled to call upon sellers (by giving notice to them in writing, as soon as possible) to substitute a similar quantity of Standard copper, of the quality or produce stipulated for by these rules, and such substitution shall be made not later than 3:30 p.m. on the first working day following the notice of rejection of the original parcel or parcels. Should the contract be for a special brand, or brands, sellers shall, if possible, substitute the same brand, or brands, and of the proper quality of produce fixed by the rules; but if unable to thus substitute, or in cases where it becomes a question of special damages, and they are unable to agree with buyers the question of damages shall be settled by arbitration, according to general rule B, and the costs of arbitration shall be borne by sellers.

Personals

J. R. Finlay has returned to New York.

C. S. Herzig is still at Matagalpa, Nicaragua.

Dr. R. A. F. Penrose, of Philadelphia sailed for Europe, Feb. 6.

Dr. Joseph Struthers has been elected secretary of the Engineers' Club, New York.

G. L. Norris has been appointed engineer of tests for the American Vanadium Company.

John W. Dunn, president of the International Steam Pump Company, has resigned on account of ill health.

John N. Steele has been elected a director of the Cumberland-Ely Copper Mining Company, in place of George E. Gunn.

Robert T. Hill has gone to Nevada to spend a month in the study of conditions at Alunite. He is accompanied by F. B. Irvine.

S. W. Eccles, president of the American Smelting and Refining Company, was recently at El Oro, Mexico, looking over some mines.

F. N. Flynn, recently at Denver, has opened an office and reestablished his headquarters as a mining engineer at Globe, Arizona.

Ellard W. Carson, of Los Angeles, Cal., has been appointed superintendent of the Pico Basin Mining Company, near Yuma, Arizona.

Anton Grønningsater, formerly chief chemist of the Deloro Mining and Reduction Company, has gone to Norway on professional business.

William C. Frechurn, of Britannia Beach, B. C., has gone to Alaska, to start up the Mt. Andrews mine near Ketchikan for Mr. Lichtenstein, one of the owners.

Frederick H. Brainard and J. Phillips Furbeck have opened an office at Benton, Wis., as consulting mining engineers, under the firm name of Brainard & Furbeck.

Dr. Henry S. Washington, of Washington & Lewis, New York, mining geologists, has returned to Brazil, where he will spend three or four months in professional work in the diamond fields.

Edward C. Westervelt has been elected president of the Santa Fe Gold and Copper Mining Company in place of J. H. Susmann, resigned. Mr. Westervelt is secretary of the Tennessee Copper Company.

S. E. Bretherton is now consulting mining and metallurgical engineer, at San Francisco, Cal. He continues to act as general manager for the Great Western Gold Company but is also consulting metallurgist for several other companies.

Edward Flynn, former president of the United Mine Workers of America in Alabama, has been appointed chief State mine inspector, of Alabama, Robert Neill, of Dora, has been named assistant State mine inspector, taking the place of Mr. Flynn, who was promoted. James Hillhouse is the other assistant inspector.

Obituary

Col. Joseph A. Andrews, who died in Newport, Ky., Jan. 26, aged 69 years, was founder and president of the Andrews Steel Company, whose works were built under his charge. He was also president of the Newport Rolling Mills Company, and had been for many years engaged in the manufacture of iron and steel.

Societies and Technical Schools

American Peat Society—A meeting of the New York section was to be held Feb. 13, at which there was expected a paper on the peat resources of the United States, and a discussion on the manufacture of gas from peat.

Anglo-American Club—This club, at Freiberg, is urgently in need of the addresses of old members. They are requested to send their present addresses to B. A. Johnson, honorary secretary, at Freiberg, Saxony, Germany.

Stevens Institute of Technology—The Alumni of the institute will have their annual dinner on Friday, Feb. 19, at the Hotel Astor, New York. A large attendance is expected, and among the speakers will be President Alex. C. Humphreys, of Stevens Institute; Alfred Noble, Col. H. G. Prout and others.

Massachusetts Institute of Technology—Doctor Jaggar, of the geological department, announced recently that money had been subscribed for a geophysical laboratory, which will be erected somewhere in the vicinity of Boston. It will be earthquake proof, and will contain modern apparatus for the study of earth movements. Professor Jaggar hopes that this will be the beginning of a movement to establish similar laboratories in other parts of the country and of the world.

University of California—With over 230 students enrolled in the College of Mines at the University of California it became necessary to provide S. B. Christy, professor of mining, with an associate and Edward B. Durham has been selected. He will have charge of the field work in mine surveying and mapping, which is a course open only to such mining students as have complied with the duties of the first year work in surveying. Professor Durham will also have charge of the

course in explosives, rock drilling and blasting. This enlargement of the mining staff will be of great advantage to the many students now at work.

Scranton Mining Institute—At a meeting held in Scranton; Penn., Jan. 18, the following officers were elected: Hubert D. Johnson, president; P. J. Moore, vice-president; J. P. Jennings, secretary. The following papers were read and briefly debated: "Electricity in the Mines," E. M. Walthall, electrical engineer, Pennsylvania Coal Company; "The Effects of Example and Discipline in the Government of Mines," P. J. More, State mine inspector; remarks, William Allen, superintendent Scranton Coal Company. Apart from the technical papers, M. J. Martin delivered an interesting address on "Legal Responsibilities of Employer and Employed." Mine Inspector H. O. Prytherch delivered an address on "Hidden Dangers and Invisible Enemies."

Appalachian Engineering Association—The annual meeting for 1909 was held at Morgantown, W. Va., Feb. 6. After the election of officers the following papers were then read and discussed: "Municipal Shortsightedness," by Prof. D. C. Weller, Waynesboro, Penn.; "Methods Used and Results Obtained in Triangulation of the Fairmont Region," by John G. Smyth, chief engineer, Fairmont Coal Company; "Reinforced Concrete Construction," by President A. Wagner; "The Surveyor vs. The Engineer," by Guy B. Hartley, of Morgantown, W. Va. At the evening session the program included a stereoscopic lecture on "Machine Mining with the Electric Puncher," by L. F. Crawford, of Pittsburgh, followed by E. A. Schubert, and short talks by Professors Morris and Boughton, C. McC. Lemley, Dr. I. C. White and others.

Montana Society of Engineers—The annual meeting was held at Great Falls, Jan. 7-9. Two days were occupied in visits to plants near Great Falls, including the Boston & Montana smelters. At the business meeting the following officers were chosen: President, Charles H. Bowman; first vice-president, Frank M. Smith; second vice-president, Fred W. C. Whyte; secretary and librarian, Clinton H. Moore; treasurer and member of the board of managers of the Association of Engineering Societies, Samuel Barker, Jr.; trustee for three years, Theodore Simons. The reports of the secretary and treasurer were read and approved and referred to the trustees. At the afternoon session the address of the retiring president, Archer E. Wheeler, was read. A thesis by Joseph H. Harper, entitled "Hydraulic Tables," was read by the secretary, followed by others from Theron M. Ripley, S. B. Robbins and F. W. Blackford. The meeting closed by a general discussion of several engineering topics.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at
San Francisco, Goldfield, Butte, Salt Lake City and Denver

REVIEWS OF IMPORTANT EVENTS

San Francisco

Feb. 3—The rain storms continue throughout the State and more particularly in the mining regions. At Nevada City, for example, 31.85 in. of rain fell in January, which is nearly as much as fell during the entire rainy season last year. Most of the mines are having trouble with surface water, and those with electric pumps are handicapped by lack of full supply of power. The water- and electric-power plants in all sections are having trouble. Considerable work is being done in the way of tracing croppings as the floods have cleared ravines, etc., so that experienced miners have a good chance to look over the ground. The storm has also afforded many mines chances to slice off pieces of ground which have remained unworked through lack of water, and ground sluicing is going on among the placer miners to a larger extent than has been the case in years. Even in places where the water runs down as soon as it stops raining, work is pretty steadily carried on as the rains appear almost ceaseless. The warm rains have washed off the snow up to the timber line, but in the higher altitudes the snow is piling up at a great rate, much to the delight of the mining communities, as there is now no fear of any water shortage the coming season. The rivers are all bank full with the rains and melting snows. At places on the summit of the Sierra the snow is now 30 ft. deep and still falling.

A suit involving magnesite deposits in Sonoma county has been brought by George Madeira and the Western Carbonic Acid Gas Company against the Sonoma Magnesite Company. An injunction is asked against the defendants to prevent them from interfering with mining work and a decree is also asked to quiet title to the magnesite mine in question.

The miners of Tuolumne county and the Chamber of Commerce of that county do not like the present plan by which San Francisco expects to get a water supply from lake Eleanor and the Hetch-Hetchy valley. They want the intake of the water to be above the mining belt. They demand that the water in the proposed reservoirs shall be diverted from the Tuolumne river at or above a point a mile below the confluence of Jawbone creek. They insist that the diversion of such water at any point below will paralyze all mining in Tuolumne county and render worthless mining property valued at millions of dollars.

About eight miles east of Paradise

Spring and 24 miles northeast of Otis—the borax camp—some rich gold ore has recently been uncovered in San Bernardino county. There is a rush from other parts of that county and adjoining ones to this new mining section.

The copper camp of Greenwater, in the Funeral range of Inyo county, is again showing signs of activity and numbers of men are going in there.

There is a law in Nevada county which forbids the owners of abandoned prospect holes and shafts to leave them unfenced. It has not, however, been enforced with much vigor and as a result several fatal accidents have occurred by men falling into such holes. Now the district attorney of the county has published a notice that he will enforce the law.

Goldfield, Nevada

Feb. 2—The total output of the Tonopah mines for the week ending Jan. 30 was 4668 tons. The Tonopah Mining Company mined 2500 tons; Belmont, 600; Midway, 100; West End, 100; Jim Butler, 300; MacNamara, 300; and Montana-Tonopah 708 tons.

The fire that started in the Sutro tunnel near where it joins the vein was confined by bulkheads to a space of 200 ft. and has now been put out; a few miners were slightly injured.

The Pioneer strike continues to be the chief topic of conversation in mining circles. The town of Pioneer is experiencing an old-time boom and now has a population of between 400 and 500 inhabitants. Frame buildings are being erected as rapidly as the lumber can be hauled and every line of trade is well represented; both the Tonopah and Tidewater and the Clark railroads have made preliminary surveys to the camp, and a telephone route is now being surveyed. It is reported that the Nevada California Electric Power Company will extend its lines to the town in the near future; over 50 applications have been made for leases on the Pioneer and adjoining grounds. The permanence of the camp greatly depends on the striking of ore in the crosscut from the 210-ft. level; the latest reports from this level are favorable, as the crosscut now 60 ft. long is apparently approaching a footwall.

The Pioneer Oil Company, of Nevada, composed of Goldfield men, and holding about 50,000 acres of supposed oil land near Indian Springs in the southern part of the State, is making preparations to

drill on two different sections of its ground.

It is reported that the Western Pacific has arranged for the purchase of the Nevada-California-Oregon Railway a narrow-gage road extending from Reno to Madeline and which crosses the Western Pacific 30 miles north of Reno.

J. W. Durfee, the contractor who sunk the shaft at February Premier lease on the Consolidated Company's ground 300 ft. in 48 days, was the recipient of a gold watch presented by the directors of the leasing company. This is claimed to be the record for rapid sinking in the camp.

Among the many bills to be presented before the Nevada legislature at its present session which began Jan. 18, several have a direct bearing on the mining industry. A bill regulating mining operations and calling for the appointment of a State mining inspector will be introduced. Organized labor will demand the enactment of law providing for the liability of employers in loss of life and for accidents occurring in and around the mines; also the enactment of a law giving laborers a first lien upon a building where construction may involve an action for wages, the expense of collection in both cases not to borne by the plaintiff. A bill making eight hours a day's work at gypsum mines will also be introduced, and also one providing that no powder more than six months old shall be sold or used in any property, as powder in time changes and becomes dangerous to handle.

The Western Ore Purchasing Company, which is already operating three samplers in Nevada, will build a fourth this year in the southern part of the State. While the location has not been decided upon, it will be settled as the MacNamara has ated at the junction of the Clark road from Goldfield and Tonopah with the Salt Lake route between Los Angeles and Salt Lake City.

The fight between the MacNamara and the Tonopah Extension companies involving the question of extralateral rights has surrendered all claims to the vein beyond its north side line which divides the two properties. The action was commenced four years ago by the Tonopah Extension securing an injunction restraining the MacNamara from entering its premises on that vein. As a result of this adjustment and that with the West End involving the same vein, the MacNamara is now bounded by vertical lines from the two properties mentioned, at least as far as this vein is concerned.

Salt Lake City

Feb. 5—The shaft at the Ohio Copper Company's property is now about 920 ft. deep, and the raise is 225 ft. above the tunnel level. It is expected that connection will be made by the end of February. This will greatly facilitate ventilation. Twenty men are now at work installing machinery in the new 2400-fm mill, and it will be ready for operation in a short time. Mr. Graves, president of the company, announces that the Bingham Mines Company will resume work on its Dalton & Lark property at once. The Dalton & Lark is a lead-silver producer, and will ship ore to the American Smelting and Refining Company. The Commercial property, owned by the same company, contains a copper-sulphide ore. It is expected that before long a contract with the Garfield smelter will be drawn up; as soon as smelting arrangements can be made work at this property will be started. The Bingham Consolidated smelter, formerly operated by this company, has been closed by the courts, and for the present will remain idle. At the Eagle & Blue Bell mine in Tintic, which is also owned by the Bingham Mines Company, work is being carried on by leasers. The company expects to start a winze from the 1600-ft. level within a short time.

At the Bingham-Butte mine the underground shaft from the lower-tunnel level will be sunk 200 ft. deeper. This shaft is now almost 200 ft. below the tunnel, and has exposed considerable ore.

The Centennial-Eureka, the greatest mine in Tintic, shipped approximately 112,000 tons during 1908. The output was considerably smaller than in 1907, on account of the shutdown of the United States smelter at Bingham Junction, which lasted several months. During this shutdown some ore was shipped to the company's California smelter. The company is said to have more ore blocked out now at this mine than at any period in the history of the mine. The shaft is now below the 2200-ft. level and will be sunk to a depth of 3000 ft. At present the pumps are handling about 12,000 gal. of water in 24 hours.

Ore shipments from the Tintic for the week ending Jan. 29, were as follows: Centennial-Eureka, 12 cars; Eureka Hill, 2; Eagle & Blue Bell, 1; May Day, 4; Yankee, 2; Ajax, 1; Sioux Consolidated, 12; Dragon Iron, 32; Colorado, 39; Brooklyn, 1; Beck Tunnel, 5; total, 141 cars. The May Day mill shipped two cars of concentrates. The Tintic smelter received 84 cars of ore from Tintic mines and shipped four cars of bullion to Eastern refiners.

On Feb. 1 the United States assay office, at 52 Post Office place, opened its doors. The first bullion to be received came from the Consolidated Mercur Gold Mines Company. The office is one of the most complete and up-to-date in the

United States, and is maintained by the Government for the assay and purchase of gold bullion. The bullion is shipped to the mints and there refined and coined. J. U. Eldredge is assayer-in-charge.

The annual report of the Utah Copper Company will be issued some time during the current month.

The Garfield smelter is treating nearly 2800 tons of ore per day, and its capacity will be increased until about 3500 tons per day can be taken care of. At the Murray smelter five lead furnaces are running full blast, and the sixth will be blown in as soon as the snow goes away so that ore can be shipped from Alta and other snow-bound camps.

Work at the Transportation tunnel of the Bingham Metals Mining Company has been going ahead so quietly that few persons have taken note of it, or appreciate what this tunnel will mean to Bingham. The tunnel is now nearly 2500 ft. long and being driven ahead at the rate of 60 ft. a week. Operations are now under way to increase the advance to 90 ft. per week.

Butte

Feb. 4—The annual meeting of the Montana Mining Association was held in Helena on Feb. 1. The following were elected officers: President, T. L. Greenough; vice-president, W. G. Conrad; secretary-treasurer, F. B. Linderman. The executive committee is composed of the following: E. A. Spriggs, Dr. P. S. Musighrod, C. E. Morris, Owen Byrnes and J. A. Rowland. The report of the executive committee showing progress made during the past year states that the association smelter at Ponderay, Idaho, has been in operation for several months and has been successful in every way. The ultimate purpose of the association is to build a smelter within the State of Montana at some central point, should conditions warrant it. It is further stated that considerable reduction in freight rates has been accomplished through the association representative who appeared before the State railroad commission. A committee was appointed for the purpose of securing legislation, State and national, which it is deemed will be helpful to the mining industry in general.

A default judgment in favor of Alonzo W. Evans and against the Lake Shore Gold Mining Company for the sum of \$10,123, was recently granted in the local district court. The action was brought by Evans and a number of other stockholders for the purpose of recovering the amount they had paid for stock in the company, they claiming that misrepresentations had been made to them regarding the value of the company's property in Madison county.

In the case of the United States against the Northern Pacific Railway Company

and its several subsidiary companies, brought in the United States Circuit Court for the purpose of securing for the Government certain coal lands for which patents have been issued to the railway, arguments were heard and submitted before Judge Hunt at Helena the latter part of January. The case arises out of a grant to the railway from the Government. In the act granting to the company certain lands, the provision was made that the company might exchange its original lands for any other lands nonmineral in character. At the time that the railway made its exchange, the lands it took were classified by the Government as nonmineral in character. Since that time the lands have been proved to be highly valuable for their coal deposits and the Government now seeks to regain them, basing its action on the claim that the classification by the Government engineers was not necessarily conclusive, and that upon the discovery of the mistake the Government has the right to retake the lands in question.

At a recent meeting of stockholders of the Butte-Montana Mining Company, held in Butte, the following were elected directors for the present year: John P. Browne and W. H. Lindsay, of Butte; J. G. Bennett, John B. Chapman, W. B. Chapman and M. K. McMillan, of Pittsburgh; R. A. Kerr, of Duluth. At a meeting of directors held immediately subsequent J. P. Browne was made president, J. G. Bennett vice-president, and W. H. Lindsay secretary and treasurer. A plan of reorganization was considered by the directors in which it was proposed to increase the capitalization from \$1,000,000 to \$2,000,000 and to change the par value of the shares from \$1 to \$10. No definite action was taken however.

In a circular letter to stockholders the directors of the Raven Mining Company have offered each stockholder an opportunity to purchase one share for every 10 now held by him, at the rate of \$1 per share. The purpose of the offer is to create a fund for continued development work. The Montana Iron Works, a Butte corporation, has begun an action against the Reims Copper Company for the purpose of foreclosing a materialman's lien upon the Combination claim of the latter company.

Denver

Feb. 6—In the Cripple Creek district, the report of the Portland Gold Mining Company shows that the total gross value of ore produced by the mine since the first shipment by the company in April, 1894, amounts to \$28,490,442. Four dividends, amounting to \$480,000, were paid during 1908. The total dividends disbursed to date are \$8,277,080. The cash balance on hand is \$260,000. Other interesting features in the report are that the mine now has 40.25 miles of under-

ground workings, and the statement that there are millions of tons of low-grade ore exposed that will pay to mine and mill. Further it appears that, following the example of Stratton's Independence, a 300-ton or 500-ton mill is to be built at the mine for the treatment of these ores, and the immense dump, and at a cost of from \$200,000 to \$400,000. It is further stated that good ore is being found at the 1500-ft. level, but that the high-grade ore, which is known to exist at the 1600-ft. level, cannot be mined until the deep drainage tunnel unwaters the district. This tunnel has now covered a distance of 5000 ft., and is expected to tap the chief water course at 1,637 ft. from the tunnel portal. The progress is at the rate of from 10 to 12 ft. per day.

The Vindicator Consolidated, whose mines are on Bull hill, holds its annual meeting on Feb. 11. The report states that the mine produced 33,035 tons last year, of a bullion value of \$942,643, and dividends were paid amounting to \$225,000.

Reports, apparently well authenticated, are at hand today from Leadville, that the Bald Mountain tunnel has intersected the great Sunday fissure, which produced its millions in the past, but which ceased to pay owing to the great cost of pumping and of transportation of its ores. The strike was made 780 ft. below the surface, about 300 ft. below the old workings, and 2600 ft. from the tunnel portal. It is stated that the entire breast is in lead ore, carrying silver and gold.

It is also just reported that the upraise which is being driven from the main Dinero tunnel, in Sugar Loaf mountain, has penetrated a big shoot of high-grade silver ore, supposed to be the same as that from which the old Dinero shaft produced its millions 20 years ago. This mine is in the granite which underlies the Leadville mines, and this discovery accentuates the belief which is held by many that there may be pay veins in the granite below the sedimentary deposits of the Leadville district.

The Denver, Laramie & Northwestern, from Denver, northward, with its projected terminus at Seattle, is under construction, as is also the Laramie, Hahns Peak & Pacific, with 38 miles in operation, 18 under the construction, and it is said with the money ready to build to the coal beds of North Park. Here is a seam 40 ft. thick in one place and 60 ft. thick at another, and both exposed on the surface. This is a fine lignite, low in ash, and about 44 per cent. fixed carbon, and 14 to 16 per cent. moisture—not a stocking or carrying coal, however, as it slacks rapidly on exposure to the air, but for power purposes at the mine most excellent. This line has its northern terminus at Laramie, on the Union Pacific. The Saratoga & Encampment railway, built from Walcott on the Union Pacific, south to Encampment by

the Penn-Wyoming Copper Company, is said now to be controlled by the Chicago & Northwestern, and that 25 miles more has been let for construction, its objective point being the coal of the Yampa Field in Routt county. This is more than probable, as the Chicago & Northwestern, with its 8000 miles of track, has about 1200 miles through a country practically devoid of coal. Three surveys have been made, and the plats filed, for a line from Wamsutter, on the Union Pacific, to Craig, in the center of the Yampa coal-field, and on the projected line of the Moffat road—also reaching for coal for the great Union Pacific system. The Denver, Northwestern & Pacific is running daily trains to Steamboat Springs, and shipping coal to Denver from the same field, and will be pushed on westward through its center to Salt Lake City.

A bill has been introduced in the Colorado Legislature providing for the appointment of an ores commission, which shall have the same powers over the smelters within the State as the Interstate Commerce Commission has over railways. The bill provides for the return of ores to the vendor in case the net price be not mutually agreed upon, and provides that should the ore have been mixed with other ores so that it is impossible to return it, the smelting company shall be liable for twice the value of the ore. The bill further provides penalties for rebating or any discrimination in the purchase or treatment of ores. The commission is to consist of three members, one of whom shall be the State assayer.

Indianapolis

Feb. 8.—Albert A. Sams, assistant State mine inspector, has occasioned the arrest of Patrick Bartley, superintendent of the Menden coal mine, near Chandler on three charges. The affidavit charges Bartley with wilfully neglecting to have the Menden mine examined last August by a competent fireboss before the men entered for work, and with acting as his own fireboss Aug. 8, while superintendent of the mine and without license. There is much feeling over the matter.

Miners and operators appeared before legislative committees during the past week to discuss the bills introduced affecting mines and mining. The Bland bill, which would widen the space at the sides of the tracks in coal-mine entries; the Higgins bill, which would compel the mine operators to sharpen 3¼-in. drills if the miners demand it; the Mugg bill, providing for the construction of hoists in escape shafts in all mines in the State; the Kayser bill, providing for the creation of an examining board of miners in each county and for licensing miners, and the Bassett bill prohibiting coal-mine operators taking out indemnity insurance against judgments at law in case of injury or death to an employee. These are

hard problems and have provoked spirited arguments before the committees by the miners, the operators and their attorneys. None of the bills has been recommended for passage as yet.

The judgment of the lower court quashing an indictment against C. E. Barrett, secretary of the Vandalia Coal Company, for failure to comply with the statute requiring that in entries to mines there shall be a space of 2 ft. outside the rails of all car tracks, was reversed by the Supreme Court on Feb. 4. The statute contains an exception as to strata 3 and 4, in the block coalfields. Barrett's men were working vein No. 4, but it was not in the block-coal district, and bituminous coal was taken out. The Supreme Court holds that this classification of coal mines is constitutional, by reason of physical differences between the two sections of the coalfields. Additional legislation is now pending in the legislature on the same subject which provides that the entries to all mines must provide 2 ft. of space on each side of the width of the car used.

Toronto

Feb. 6.—Dr. Eugene Haanel, director of mines, has returned from a trip to Dumnarfvat, Sweden, undertaken to witness the operation of the new electric furnace for iron smelting. The plant resembles a blast furnace in which the tuyeres are replaced by electrodes, a three-phase current being employed. The charge passed down through the shaft gradually and uniformly, the electrodes needing no regulation, not being moved for five days. In another furnace at the Dumnarfvat works, a three-phase current and two electrodes are used, the bottom of the furnace furnishing the third electrode. The special advantage of this arrangement is that the three-phase current produces a rotation of the bath in a vertical plane, bringing new material continually into the slag line for purification.

Doctor Haanel, when in Europe, also made investigations into the production of gas from peat and in pursuance of this object the Canadian government has appropriated \$15,000 for the erection of a fuel-testing plant at Ottawa, the machinery for which is on the way from Germany. It will test the qualities of Canadian peat as a gas producer from which electricity can be generated. An appropriation has also been made for the purchase by the government of a peat bog, on which machinery can be set up for demonstrating the best methods of making peat fuel for electrical purposes.

The new route to Gowganda via the Canadian Northern Railway to Sellwood, north of Sudbury, and thence by sleighs was regularly opened on Feb. 2. The following day an official party left to make an inspection of Gowganda camp.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Alabama

JEFFERSON COUNTY

Upon the petition of unsecured creditors Judge Jones in the Federal court has appointed James Bonneyman, former general manager of the company, and A. W. Smith, president of the Birmingham Trust and Savings Company, as receivers for the Birmingham Coal and Iron Company. The receivers have taken charge of the properties, instructions being given that there is to be a continuation of operations. The property consists of two furnaces, coal and ore mines, coke ovens and limestone quarries. The officers of the Birmingham Coal and Iron Company, H. M. Atkinson, of Atlanta, Ga., and others, are also officers of the Atlanta, Birmingham & Atlantic railroad, which corporation is also in the hands of receivers.

Arizona

CONCHISE COUNTY

Grading has begun, and the right of way is reported to have been secured for the Colorado & Mexico railroad from Douglas to Courtland.

Calumet & Arizona—The production of copper for January was approximately 5,000,000 pounds.

Copper Queen—The smelter broke all previous records and produced 9,500,000 lb. of copper during January.

GILA COUNTY

Globe—Despite the brief shut-down at the mines on account of labor troubles, the January output of the smelter is estimated at 3,000,000 lb. of copper.

Black Warrior—Regular shipments of ore are being made to the Old Dominion smelter.

GRAHAM COUNTY

Arizona Copper—Repairs, due to the recent fire at the smelter, are being completed. The output for January is estimated at 1000 tons of metal.

Arizona Power and Water Company—The company proposes to build two large dams above Clifton for the manufacturing of power for the various companies of the district. The first dam, which will be 100 ft. high, is to be built across the San Francisco river.

The incorporators of the company are Dell M. Potter and Geo. F. Reed, well known men of the district, but foreign

capital will largely assist in the undertaking. It is capitalized at \$1,500,000.

Gold Belt Development and Reduction Company—A new board of directors was recently elected and \$50,000 secured for development work and machinery.

Morenci Southern Railroad—Morenci is connected with Guthrie, a point on the Arizona & New Mexico road by this narrow-gage road which belongs to the Phelps-Dodge interests. It has ample equipment for its enormous freight traffic. Because of the increasing importance of Morenci and the district the company intends to increase its passenger equipment.

New York-Arizona—The Lillian tunnel has cut one shoot of ore showing free gold, but as the objective point is only about 100 ft. from the present face, it has been determined to drive that distance before proceeding with the development of the orebody already exposed. The gasoline engines have been installed and the hoists and compressors are in operation. Lower down the mountain the company has a 70-ft. shaft with a 50-ft. drift showing a promising vein of copper sulphide, but the water necessitated the abandonment of work until pumps can be installed.

YAVAPAI COUNTY

Monark—Plans are being made for the erection of a 100-ton stamp mill.

California

AMADOR COUNTY

Argonaut—The ore being mined at this property, Jackson, carries more sulphurets than formerly and more concentrators have been added to the mill.

Bunker Hill—The ore is averaging \$7.50 per ton and in the last six months has yielded \$125,508, of which \$42,000 was paid out in dividends.

CALAVERAS COUNTY

Hayston—This mine in Fischer district, W. W. Dunlap manager, now has ore in its shaft averaging \$10 per ton. The mine is a south extension of the Blue Jay where men are now being set at work.

EL DORADO COUNTY

Alpine—Nixon & Wingfield being unable to secure an extension of their option so as to sink 200 ft. have given up this mine to the company represented by D. C. Lane, of Los Angeles, which is now expected to work it.

HUMBOLDT COUNTY

Klamath River Mining Company—This company owns the Miller placer mine on the Klamath river, three miles from Weitchpec, where a sawmill, flumes, etc., are to be put up. There are 300 acres of mining ground in the property.

INYO COUNTY

Graphite—W. G. Scott, manager of the Inyo Mines Syndicate, has located some promising graphite claims.

Gray Butte—At this mine, seven miles from Casa Diablo, a tunnel is being opened. A Marks quartz mill is about to be placed on the mine.

Key Gold—This company at Greenwater is reported to have bought from "Death Valley Scotty" and his partner, Wm. Keyes, the mine from which they have taken gold.

MARIPOSA COUNTY

1909 Mining and Milling Company—This company has been organized to work the old Enterprise or Barcroft mine near Hornitos. G. P. Cummings, of Fresno, is secretary, and Ed. Mahoney, of Hornitos, manager. There is an eight-stamp mill and a new air compressor is being installed.

NEVADA COUNTY

Golden Gate—A new turbine pump has been installed and as soon as the water is removed operations will be resumed.

Midas—At this mine, owned by Grass Valley men, they have started drifts on both sides of the shaft. There will soon be ore enough out to start the mill.

PLACER COUNTY

McGeachen Gravel Mining Company—This company operating the Jupiter and McGeachen drift mines at Iowa Hill, has purchased the Big Dipper claim at that place which will permit the opening of valuable mining ground lying east of the Big Dipper. I. E. Rose is superintendent.

SHASTA COUNTY

Gladstone—A new electric line to carry ore from mine to mill is being put in and 10 stamps are to be added to the mill.

Midas—This company at Knob has 100 men at work and the 20-stamp mill is running steadily. The old ledge on the lowest level continues rich.

SIERRA COUNTY

Forest Green—This mine, at Forest, is supposed to be an extension of the Tightner and Red Star mines. The shaft is to be continued to 500 ft. A 10-stamp mill and cyanide plant are to be installed. J. C. Chandler is president of the company.

Twenty-One—The tunnel is now in 500 ft. Surface equipment will be installed when the weather permits.

SISKIYOU COUNTY

Grouse Creek—This placer, operated by Welch & Sons, has started up with three giants at work, there being plenty of water.

Shebo—A contract has been let at this property at Indian Creek to sink deeper. A new hoist is being put up.

TUOLUMNE COUNTY

Black Oak Mining Company—The mine is unwatered to the 600 level and the mill is kept at work on the old dump. Roger Knox is superintendent in place of M. A. Knapp.

Draper Mining Company—The tunnel has been partly cleaned out and re-timbered and the shaft retimbered down to where the ground is safe.

Colorado

ADAMS COUNTY

A vein of anthracite is reported found near the Weld county line, at a point about 20 miles from the Union Pacific and 12 miles from the Chicago, Burlington & Quincy road. A number of locations have been made.

LAKE COUNTY—LEADVILLE

Bald Mountain—A little over eight months ago this company started to drive a tunnel 2200 ft. to the Sunday vein on Bald mountain at the head of California gulch. The edge of the mineral zone has now been reached. The tunnel has been driven into solid mineral for a distance of 12 ft. and the footwall has not, as yet, been reached. The ore in the vein is a lead sulphide carrying some silver and gold. The mineral was encountered at a depth of 950 ft. from the surface. When the footwall is encountered, the work of developing the orebody will be started, and this will be carried on for 3000 ft., the length of the vein. Before the whole length of this ground is opened it is the intention of the management to start and make connection with the shaft on the surface, which is down 450 ft. This is the most important strike made this year, as it is in virgin territory.

Rosse Tunnel—A fair body of ore has been opened in this adit, St. Kevin, and shipping will start in a few days. The company that is working this tunnel is also driving the Birdella tunnel and making good progress with the work.

Result—The lessees on this mine, Stray Horse gulch, are shipping three carloads per week of an excellent grade of oxidized iron, and this could be doubled if the roads were in better shape. In the meantime the ore is being broken and held in the bins.

Robert Emmet—From this mine, Iron hill, the lessees are shipping regularly a good grade of iron, and at the same time prospecting in new ground.

SAN JUAN COUNTY

Joe & John—These claims in Prospect basin have been sold to the Allerton Mining and Milling Company, which proposes to begin development as soon as the weather will permit.

TELLER COUNTY—CRIPPLE CREEK

Portland—The annual meeting of the stockholders of this company was held in Cheyenne, Wyo., and the following directors were reelected: Frank G. Peck, Thos. F. Burns, Dr. D. H. Rice, Irving Howbert and Carl Chamberlin. The board was elected by about 2,000,000 shares while the minority vote, which was cast by James F. Burns, was less than 500,000 shares. The report of President Peck shows that the gross production of the mine for the past year was 94,311 tons of ore of the gross value of \$19.45 per ton making \$1,834,081. The total receipts for the year were \$1,836,869; total expenditures \$1,278,030, leaving a profit of \$588,839. Cash on hand at the beginning of 1909, \$269,193. Dividends paid in 1908, \$480,000. Some new strikes of importance have been made in the lower levels. A large amount of experimenting has been done with the low-grade ores and it is proposed to build at an early date a mill. Some litigation has also been settled during the year. The output of this property up to Jan. 1, 1909, is 949,381 tons of ore of the gross value of \$28,469,423. F. M. Kurie, of Victor, is general manager of the mine.

Vindicator—The annual meeting of the stockholders of this company will be held in Denver Feb. 11. The production of the property for the past year amounted to 33,035 tons of ore of the gross value of \$942,643; \$225,000 were paid in dividends. E. J. Trevarrow is superintendent of the property.

Mabel M—This property, owned by the Gold Dollar Consolidated company, is making a heavy production from the lease operated by the Union Leasing Company. C. G. Jackson, of Cripple Creek, has charge of operations.

Isabella—At the annual meeting of the stockholders of this company held recently in Cheyenne, Wyo., the old board of directors was elected for the ensuing year, as follows: J. A. Hayes, president, Irving Howbert, vice-president, G. D. Kilborn general manager and W. T. Doubt secretary and treasurer. The production for

the year amounted to \$391,177. After deducting mining, transportation and treatment charges and payment to lessees the net profit at the mine was \$82,324. General office expenses and payment of some debts amounted to \$46,856 and the net profits of the company for the year were \$35,468. The mine is worked both by leasers and on company account. G. D. Kilborn, of Colorado Springs, is general manager.

Indiana

DAVIES COUNTY

The discovery of a vein of cannel coal on the farm of J. P. Cavanaugh five miles east of Washington has been made at a depth of 110 ft. A second vein of bituminous coal 3 ft. in thickness underlies the same farm. Plans are being made to develop the find and to secure a spur railroad to ship the product of the shaft when completed.

Michigan

COPPER

Seneca—A depth of 230 ft. has been reached in the shaft, and a crosscut is well under way to intercept the Kearsarge lode. The shaft is in the footwall and approximately 60 ft. from the lode. A hoisting engine of sufficient capacity to serve this shaft during the development stage has been delivered and will soon be ready to run.

Copper Range—Work has been discontinued on the Globe tract which has been held under option for some time. A shaft was sunk to a depth of 1000 ft. to intercept the Baltic lode, but when found the lode material was not of commercial grade. Considerable drifting was done at that depth, but nothing was found to warrant further explorations, so the shaft will be abandoned. Diamond drilling in search of the Atlantic and other lodes continues on sections 7 and 8. Conditions at the Trimountain are improving with depth.

Ojibway—No. 1 shaft has reached the second or 650-ft. level and should soon cut the lode. The lode where intersected at the 500-ft. level a few feet from the shaft, was of good grade, and consisted of two beds separated by about 14 ft. of trap rock. A crosscut is also being driven from No. 2 shaft on this level; this should cut the lode in a few days. The orebody where opened from No. 2 shaft was not as rich nor as uniform as at No. 1, but as the second level at No. 1 shaft showed a decided improvement over the first, probably as depth is obtained the shattered condition will disappear.

Superior—Sinking has been resumed below the 10th level at No. 1 shaft; with the enlarged equipment faster progress will be made. The fifth lot, about 3000 tons, has been put through the mill,

showed a saving of about 30 lb. of copper to the ton. More concentrating tables have been added to the Atlantic mill to handle the tailings, and probably a better saving will be made.

Calumet & Hecla—The first of the four units in the regrinding mill, each unit of which contains 12 Chilean mills and 48 Wittey tables, has been in service some time, and most encouraging results are being obtained. Within a few months this entire plant, which will treat about 1500 tons of tailings per day, will be in operation. The new electrically driven centrifugal pumps at No. 5 shaft have been started. These pumps will take care of all the water from the northern portions of the mine and well eliminate the hoisting of water through the Red Jacket shaft.

Allouez—The lode where cut by No. 2 shaft at a point about 15 ft. below the 14th level is highly mineralized. This shaft has been sunk in the hanging wall at a depth of 80 deg., but will now be changed to conform with the pitch of the formation.

King Phillip—The crosscut on the sixth level from the No. 2 shaft has cut the Winona lode; the lode looks much better than where opened at the fourth level.

Lake—The shaft has reached a depth of about 400 ft.; a station is being cut at that depth and driving on that level will soon begin. The north drift from the second level has cut the lode formation.

Quincy—The January output in tons of mineral for 1909 was 1300, compared with 1310 for that month in 1908, 1200 in 1907, 1215 in 1906, 1130 in 1905, and 601 tons in 1904.

Montana

BUTTE DISTRICT

Amalgamated—The mines of the Boston & Montana, Butte & Boston, Anaconda, and Washoe companies are now producing at their normal rate, the adverse weather conditions which have interfered with transportation facilities having abated.

British-Butte—The new Risdon gold dredge was put in operation by the Governor of the State on Jan. 30. The dredge has been put in shape for continued working and it is expected that regular operations will begin the first of the coming week.

North Butte Extension—The plans for reorganization of the company are still unsettled. It is reported that A. M. Andrews and R. J. Horner, who have been active in refinancing the company, have severed their relations with the management.

Tuohomni—The shaft is down 1250 ft., and sinking is progressing steadily. No further cross-cutting will be done until the 1400 ft. mark has been reached. The boiler plant on the property is practically

completed and the compressor plant is in process of construction. It is expected that both will be ready for operation by March.

Copper Eagle—A new shoot of ore was encountered the first of the week at a point about 180 ft. east of the shaft on the 350-ft. level. The shoot is more than 18 in. wide, and according to the management a sample taken across the face shows 4½ per cent. copper and \$8.50 in gold and 1030 oz. silver per ton. This is the same shoot that was encountered on the 250-ft. level at about the same distance east of the shaft.

Davis-Daly—At the Colorado shaft the new engine is in place and the steel gallow frame is nearing completion. By Feb. 15 it is expected that both will be in operation. Of late the principal development work has consisted of diamond drilling on the 1400-ft. level.

La France Copper Company—At the Lexington mine development work is being done on the 1450-ft. level. On some of the levels above, leasers are working steadily, and most of them are making regular shipments.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Consolidated Red Top—Last week two new oreshoots were opened up. One is on the 150-ft. level almost directly over the orebody from which the ore produced last month was obtained. The other is in a raise from the 300-ft. level, south of and below the big stopes. In both places the ore averages about \$90 per ton. Under the terms of the lease the company was required to sink the shaft to a depth of 500 ft. on or before Aug. 1, 1909, but the development work being carried on and the raising of ore have so taxed the capacity of the hoist, that an agreement has been made whereby the leasing company pays the Goldfield Consolidated company \$5000 in lieu of sinking the additional 200 feet.

Kalfus Lease—J. L. Kalfus, operating this lease on the Great Bend Annex property, has been granted an extension of time. A crosscut 300 ft. long has been run from the bottom of the shaft, 185 ft. deep, and should shortly cut the Great Bend vein.

Daisy—A gasoline hoist has been placed on the Detch-Brewer lease on the Daisy ground and a systematic search will be made for the oreshoot from which several shipments have been made.

Imperial Goldfield—This company, owning two fractional claims adjoining the Blue Bell on the east, is making preparations to resume work after an idleness of more than a year. There are a number of promising veins outcropping on the

property and these will be prospected at depth.

Combination Fraction—This company has leased the Nevada Goldfield Reduction Company's mill, and will treat its own ore in the future. A new strike was made recently in the company workings on the 600-ft. level.

ESMERALDA COUNTY—RAWHIDE

Murray Mill—This mill started Jan. 24 and has run continuously since. Apparently the ore treated is yielding well to amalgamation. It is reported that the owners of the Murray lease are to add to more stamps to this mill.

Kearns No. 1 Lease—This lease on the Rawhide Queen property is working 22 men on the two shifts. Ore is being sacked for shipment.

Victor Lease—On the 250-ft. level of this lease on the Coalition property, good milling ore has been found. The vein appears to be widening in depth.

Grutt Hill Mint Lease—The shaft on this lease is now 320 ft. deep. The shaft will be continued deeper as the lease extends for several years. In the winze considerable shipping ore has been found, but of course, most of the ore is of milling grade.

Murray Lease—The main quartz vein has been discovered on the 200-ft. level; where found the vein contains a narrow streak of rich ore along with milling ore of usual grade.

NYE COUNTY—TONOPAH

Tonopah Mining Company—During the week ending Jan. 30, 510 ft. of ground was broken. The mill dropped an average of 98 stamps during the week, 3145 tons of ore having a value of \$22.70 per ton were crushed, and 38 bars of bullion valued at \$34,200, together with 44,000 lb. of concentrates valued at \$10,780 were shipped, making a total production for the week of \$44,980.

Montana-Tonopah—Last week 115 ft. of new ground was broken in the various levels. The ore in the different stopes showed practically the same value. The mill crushed 904 tons of ore, 256 of which came from the MacNamara mine.

Belmont—Development work on the 1000- and 1100-ft. levels has proved the existence of a large orebody in this property. The ore now blocked out by a number of raises and winzes from these two levels shows for 250 ft. on the 1000-ft. and for 100 ft. on the 1100-ft. level and averages 6 ft. in width; all this ore is of a good milling grade.

WHITE PINE COUNTY—ELV

GEORGE—Actual transfer of control of Grouse Consolidated Mines Company to the Cole-Ryan interests was accomplished Feb. 2 at the annual meeting when Thomas F. Cole and three other new directors were

elected. Joseph L. Giroux was re-elected president. The balance sheet, brought up to Feb. 1, 1909, and covering 13 months, showed \$442,383 for ore sales; \$1,500,000 from bond sale; \$3,955,867, property account; \$1,689,660, development account; \$293,355, capital charges. Cash in bank is \$431,771, while \$572,000 was due from sale of bonds. The issue of \$1,000,000 6 per cent. ten-year bonds secured by second mortgage on the Nevada properties of the company has been authorized. It has been decided to transfer the executive offices from New York to Duluth. In addition to authorizing \$1,000,000 ten-year second mortgage 6-per cent. bonds, stockholders have also authorized an increase of stock by 200,000 shares to permit of the conversion of the new bonds. There are in the treasury of the company \$500,000 of the first mortgage bonds of the original issue of \$1,500,000. The company's authorized capitalization now stands at \$7,500,000 stock and \$2,500,000 convertible bonds. Notwithstanding the actual transfer of control to the Cole-Ryan interests the five-year pool which does not expire until the middle of 1910 is still in force. There are in the pool 465,000 shares, and the entrance of the Duluth interests was brought about by a 'partnership' agreement between the members of the pool and Thomas F. Cole and associates.

Cumberland-Ely—At the annual meeting of the stockholders at Augusta, Me., John N. Steele was elected a director in place of George E. Gunn, retired.

Utah

BEAVER COUNTY

Frisco Contact—D. P. Rohlfing is in Boston consulting with officials of this company, and it is expected that work will soon be resumed at the mine. The development consists of a two-compartment shaft 500 ft. deep, and about 800 ft. of drifts and crosscuts, which have exposed milling ore.

Nabob Consolidated—A short time ago this company started a tunnel to intersect the vein at a depth of 130 ft.; this work is being vigorously advanced. The property is near that of the Cedar-Talisman company.

Golden Reef—The shaft on this property is in ore assaying high in lead and carrying some gold. Three carloads are ready for shipment.

Black Hawk—In the Black Hawk winze about 40 ft. from the tunnel mouth a cave containing good sand carbonate ore has been opened.

Commonwealth—The west crosscut has followed an ore stringer for nearly 100 ft.; the stringer is widening as work advances.

Cedar-Talisman Consolidated—The Cedar and Talisman properties have been

consolidated, and the danger of litigation averted. The new company is capitalized for 1,000,000 shares, par value \$1 each. The Cedar company gets 350,000 shares the Talisman 300,000 and the balance is placed in the treasury. There is a shaft 500 ft. deep on the Cedar and the company is well equipped with hoisting machinery and a compressor. Some ore has been developed on the Talisman claims. The consolidated holdings comprise about 285 acres.

JUAB COUNTY

Uncle Sam—Development work is under way to determine the extent of the ore-shoot just discovered. The ore appears to be making at the bottom of the drift.

MILLARD COUNTY

Utah Mine Company—This company at Fish Springs declared a dividend of 2c. per share, or \$2000, payable Feb. 10. The usual dividend has been 3c. This was reduced in order to purchase additional ground.

SALT LAKE COUNTY

Bingham Copper—J. P. Graves, president and H. N. Sweet, director of the Bingham Copper and Gold Mining Company have been conferring with Duncan McViehe, the managing director. It is understood that the company will soon resume operations. This is the first Utah property of which Heinze acquired control. To date the property has never paid, but with the opening of the Mascotte tunnel the shipping facilities of the mine are greatly increased.

Central Standard—Three shifts will be started at once in the Mountain Maid tunnel. This should strike the extension of the Bingham-New Haven orebody within 250 to 300 ft. Development work on the Saginaw vein will also be resumed.

Utah Copper Company—In December the production was 4,174,859 lb. of copper. The total output in 1908 was 43,689,875 lb. The production by quarters has been as follows:

July-Sept., 1907.....	5,305,368
Oct.-Dec., 1907.....	7,716,712
Jan.-March, 1908.....	8,827,939
April-June, 1908.....	11,568,390
July-Sept., 1908.....	12,000,925
Oct.-Dec., 1908.....	11,592,621

The Garfield mill did not attain full operations until December, 1908. Plans are said to be under contemplation for a further addition to the milling capacity. The company is paying dividends at the rate of 50c. per quarter, or \$2 per annum, but is earning nearly twice as much. However, dividends will not be increased until an adequate surplus has been accumulated. The company hopes to reduce the cost of production to the neighborhood of 7c. per lb., direct operating charges, which will probably mean 8@8½c., including maintenance, etc.

TOOELE COUNTY

Boston-Sunshine—On the first of the month this company started work again at the mine; the mill is being remodeled.

UTAH COUNTY

Mineral Flat—At this property, in American Fork cañon and controlled by Jesse Knight, ore is being opened up near surface. The tunnel, now about 650 ft. long, should catch the ore within 500 ft. This will give a depth of 400 ft. on the vein.

UTAH COUNTY

Dutchman Lease—This lease reports a body of high-grade carbonate ore about 7 ft. wide.

Mary Ellen—In this property a vein 3 ft. wide carrying seams of galena has been struck. Work has been discontinued for the present, owing to danger from snow slides.

Müller Lease—During the six months that this lease has been running considerable ore has been shipped. One of the largest orebodies ever discovered in these claims is now being opened up.

Blue Rock—High-grade ore is being mined steadily. A carload of good ore was shipped last week.

Wisconsin

ZINC-LEAD DISTRICT

Platteville—The new shaft at the Grant County has gone through to 10 ft. of rich ore ground between the depths of 130 and 140 ft., sheets of jack measuring 5 and 7 in. in thickness.

Enterprise—Since resuming operations a great sheet of jack, averaging 2 ft. in thickness, has been uncovered in the floor of the old works.

Mitchell Hollow—A discovery of rich sheet jack has been made at this property by the Wisconsin Zinc Company.

Graham-Stevens—New York and Rochester parties have purchased a controlling interest in this mine; milling will be resumed as soon as an incline shaft is sunk.

Homestead—This company has foundations laid to install the roaster equipment obtained from the Hazel Green.

Broadway—This company has started drilling within the city limits of Platteville, west of the Grant County lease.

Hotel Mining Company—This company is prospecting by drill in the south east end of the city of Platteville.

Canada

BRITISH COLUMBIA—FERNIE

Crooks Next Pass Coal Company—At a meeting of the directors in Toronto Feb. 1 it was decided to omit the usual dividend for the past six months, owing to the heavy loss sustained in the Fernie fire.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ending Jan. 29 were as follows: Crown Reserve, 160,700 lb.; Cobalt Central, 41,238; City of Cobalt, 155,840; La Rose, 320,700; McKinley-Daragh, 121,500; Nipissing, 525,000; Temiskaming, 130,000; Temiskaming & Hudson Bay, 60,000; total 1,515,068 pounds.

Alexandra—The shaft is down 135 ft. on two promising calcite veins and will be put down to 285 ft. Crosscutting will be undertaken to reach No. 2 vein of the Bailey, about 60 ft. distant from the shaft, which has been struck by trenching.

O'Brien—The Ontario treasury has received \$49,518 being the 25 per cent. royalty on the output of this mine for the last three months of 1905.

Temiskaming & Hudson Bay—The main shaft is down 220 ft., with four levels. The shaft will be put down farther and another level started at 250 ft. A carload of high-grade ore was shipped from the 200-ft. level, the ore showing improvement with depth. The value of the high-grade ore reserves of the mine is estimated at \$1,500,000 in addition to the low-grade ore.

Crown Reserve—No. 1 shaft, now down 100 ft. will be sunk to the 200-ft. level. No. 2 shaft will be deepened from 145 ft. to the same level and the two connected at that depth. A rich vein 1 in. wide has been encountered in No. 2 crosscut running in the direction of the Kerr Lake property.

Hyland—At the 100-ft. level the vein, which assayed 225 oz. at the surface, has increased in value to 2000 oz. to the ton and is 6 in. wide. A contract has been let for sinking to 150 ft. A compressor plant has been ordered.

Little Nipissing—Work on the new shaft adjoining the Hudson Bay and Right of Way has been temporarily discontinued at a depth of 50 ft. owing to water. A promising vein shows on one side of the shaft.

Nipissing—In the Fourth of July shaft three new veins have been encountered at a depth of 135 ft. They carry 4000 oz. silver to the ton, in addition to leaf silver along the veins.

Progress—A shaft is down 30 ft. on a new vein near the Gifford extension, at which depth the vein shows 3 in. of ore carrying native silver. A compressor plant is under order.

ONTARIO—MONTREAL RIVER DISTRICT

Elk Lake Discovery—Two 60-h.p. boilers and a large compressor have been installed and the drills are showing good ore at depth.

Moose Horn—Camp buildings have been erected and a boiler and hoist installed, but the mining work is being done by hand. The shaft is down 85 ft., and when

the 125-ft. level is reached drifting will be undertaken to tap veins traced on the surface.

ONTARIO—LAKE MINNETAKIE

Northern Pyrites Company—A trial shipment of six carloads of pyrites has been sent from this mine to the Austin Manufacturing Company, Harvey, Ill. and to the Detroit Chemical Works.

NOVA SCOTIA

Dominion Coal Company—This company has closed contracts for the delivery during the present year of about 600,000 tons of coal to the Canadian Pacific and Grand Trunk railways and for 40,000 tons to the Laurentide Pulp and Paper Company.

Mahon—This mine, Inverness county, owned by a Cincinnati syndicate headed by W. P. Deppe, has been flooded from the sea owing to a fault in the strata. It is entirely submarine and is now full of water. The property, on which about \$500,000 has been expended, has been in the hands of the Provincial government since October last on account of arrears of about \$7000 for wages.

Mexico

CHIHUAHUA

Parral Output—The production of the Parral camp for the week ending Jan. 29 amounted to 5840 tons of milling ore and 2580 tons of smelting ore, a total of 8420 tons.

Sierra Plata—This company has suspended productive operations at its Los Muertos mine in the vicinity of Minas Nuevas in the Parral district. T. F. Trewet is temporarily in charge.

Chihuahua Copper Mining Company—This company, which has been until lately successfully operating in the eastern part of the State along the line of the Orient railroad, has suspended work. It is probable that the shut-down will not be of long duration.

Conchos Power Plant—It is stated that Paul Günther and associates are perfecting a heavily-financed company which plans the erection of a 40,000-h.p. electric-power plant, to be located along the Conchos river, near Santa Rosalia. The power will be sold to mining companies near Chihuahua and Parral, as well as used for irrigation purposes. Among Mr. Günther's associates are Juan Creel and Joaquin Cartazar, of Chihuahua.

Greene Gold-Silver—It is reported that this company, through its manager, C. C. Chase, has settled in full its labor claims at Ocampo, and that payment in part will shortly be made on its large indebtedness at Chihuahua and elsewhere.

San Francisco del Oro—It is now given out that plans had been perfected and

officially approved for the early erection of a large milling plant at this property reached from Parral. W. S. Harrison, who has been at the property for some time, lately departed for London to consult with the directorate, and it is expected that construction work will be started on his return within three months.

Hinds Consolidated—The directors of this Cleveland-organized company are said to have recently reported in favor of the early erection of a 500-ton milling plant at its Clarines mine in the Santa Barbara camp. Howell Hinds, of New York City, is the president and managing director. The manager at the mine is Ross B. Watkins.

Bullion Shipments—Recent bullion shipments passing through Chihuahua are the following: Republica, 40 bars of silver worth 40,000 pesos; Candemana, 6 bars silver, 6000 pesos; Batopilas, 199 bars silver, 202,000 pesos; Watterson, 9 bars gold-silver, 22,000 pesos; Lluvia de Oro, 24 bars gold-silver, 60,500 pesos. The Rio Plata company also sent out concentrates of a value of 57,500 pesos.

Promontorio—This old silver mine in the Cusiuhiriachic camp was recently acquired by the Potter Palmer estate of Chicago at a stated consideration of \$125,000, of which \$25,000 has been paid. Potter Palmer, Jr., took possession of the mine on Jan. 16 and has begun work under the direction of W. M. Crosette.

JALISCO

Imparo—A dividend of 2½c. per quarter has been declared, a total of \$63,000 on an issued capital of \$2,520,000. The mill treated 3949 tons of ore last month.

Queen Sabe—A body rich in gold and silver has been encountered on this property on the northern shore of lake Chapala. The ore will be shipped from Ocotlan.

OAXACA

San Carlos—The mine has been entirely unwatered and sinking on the shaft has been resumed. Only the upper levels were worked during last year.

Victoria-Tepada—The company has decided to erect a mill and cyanide plant on the property in the Totolapam district. This is the first mill in the district and will do custom work.

SONORA

Greene-Cannaca—The January production of copper was 3,848,000 lb., the largest monthly output since operations were resumed last July.

Arizpe—At a recent election, the resident officials elected were: J. H. Kirk, vice-president and general manager; George Young, secretary, and V. R. Walling, assistant treasurer.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, Feb. 10—The coal trade in the West remains quiet, with little or no change from last week. If anything, there are some signs of over-shipments at the leading centers and consequently lower prices forced by the desire to get rid of demurrage coal.

The report that a consolidation of a number of coal mines in southern Illinois had been arranged, which was current nearly two years ago, has been revived. Options on a number of the mines in question were given at that time to Walter J. Holbrook, but the completion of the deal was prevented by the financial stringency. It is now said that arrangements have been made to carry the plan through. The mines in the proposed merger shipped chiefly to the St. Louis market.

The Seaboard bituminous trade continues quiet and without special incident. No revival is yet apparent in the business.

Anthracle trade is dull and steady as usual. The demands of the anthracite miners, which were formulated at Scranton some time ago, have been slightly amended and approved by the general convention of the United Mine Workers at Indianapolis. They will shortly be presented to the companies by a delegation headed by President Lewis of the Union; there is little doubt that they will be rejected.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to Feb. 1, 1908, and Jan. 30, 1909, in short tons:

	1908.	1909.	Changes.
Anthracite.....	465,252	433,647	D. 31,605
Bituminous.....	2,781,830	2,867,510	I. 85,680
Coke.....	697,841	847,342	I. 249,501
Total.....	3,844,923	4,148,499	I. 303,576

Average daily tonnage, 120,154 in 1908, and 138,283 in 1909; increase, 18,129 tons.

Coal tonnage originating on the Southern Railway for the year 1908 is reported as follows: Tennessee district, 1,098,623; Alabama district, 1,896,283; total, 2,994,906 short tons.

Coal and coke tonnage of Pittsburgh & Lake Erie road, year ended Dec. 31, 1908, short tons:

	Coal.	Coke.	Total.
Pittsburgh district.....	8,089,120		8,089,120
Wampum district.....	26,904		26,904
Connellsville district.....	13,805	3,019,216	3,033,021
Other districts.....		37,179	37,179
Total.....	8,129,829	3,056,395	11,186,024
Total, 1907.....	10,891,062	4,926,396	15,816,468

Decrease in coal, 2,761,433 tons, or 25.4

per cent.; in coke, 1,869,001 tons, or 37.9 per cent.; total decrease, 4,630,434 tons.

Anthracle coal shipments in January are reported as follows, in long tons:

	1907.	1908.	Changes.
Reading.....	1,099,480	1,056,104	D. 43,376
Lehigh Valley.....	1,031,436	896,401	D. 116,035
N. J. Central.....	722,965	630,085	D. 92,880
Lackawanna.....	842,953	762,636	D. 80,317
Del. & Hudson.....	569,129	566,062	D. 3,067
Pennsylvania.....	314,890	484,682	D. 30,138
Erie.....	611,632	548,077	D. 62,555
N. Y., Ont. & West.....	246,524	240,308	D. 6,216
Total.....	5,618,330	5,183,345	D. 434,984

All the companies showed decreases; the total loss this year, as compared with January, 1908, was 7.7 per cent.

New York

ANTHRACITE

Feb. 10—The hard-coal market continues unchanged, with about the usual amount of business, but no signs of activity. The rumors of a possible strike of the miners in April do not seem to affect consumers. Most buyers probably believe that the companies have coal enough stored to carry them over some time with little inconvenience.

Prices are unchanged. The list prices for prepared sizes are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points.

BITUMINOUS

While the general market continues very quiet, there is beginning to be some talk about contracts. As most of these date from April 1, this talk will doubtless increase. It is noticeable that everyone wants lower prices, a reduction of 25c. from last year being the only proposition they are inclined to listen to.

Otherwise business is on a hand-to-mouth basis. Producers are not pressing coal for sale and are carrying very small stocks at tide. As a rule coal is not started from the mines until an order is received.

There is still a demand for gas slack, which is really bringing a higher price than run-of-mine. It has been scarce owing to the light sales of lump and 3/4-in., so that little slack has been made. The present quotations are about 65@70c. at mine.

New York harbor is very dull. Coal of good quality can be had freely at \$2.50@2.60, with ordinary coals a little lower

and run-of-mine gas \$2.25. The Sound is taking some coal, though its purchases are rather irregular. In the far East business is practically dead and there is no buying. This has rather surprised dealers who know that consumers' stocks are exceedingly low.

All-rail trade is again a little better than tidewater, and seems to be taking more coal. Car supply is abundant. Transportation is nearly up to schedule, cars taking from a week to 10 days to come through.

The Coastwise trade is quiet. Rates are still pegged on the basis of 75c. from the lower ports to around the Cape, and captains prefer to tie up rather than take less. The quoted rates for large vessels from Philadelphia are: Boston, Salem and Portland, 75c.; Lynn and Bath, 85c.; Newburyport, 95c.; Portsmouth, 80c.; Providence, New Bedford and the Sound, 65@70c. per ton.

Birmingham

Feb. 8—A quiet market and no prospect of an early improvement have brought about a curtailment in the coal mining section of Alabama, is equal to about 5 per cent. so far. The weather this winter has not been conducive to a big demand for coal, and coke has been stacking up. Exactly how long this will be on cannot be stated.

Chicago

Feb. 8—The coal market has weakened again with the passing of another cold wave and shows not only notably lessened demand for domestic coals, but also for the larger sizes of Illinois and Indiana. Screenings are unusually strong for the time of the year and nearly all western lump is subject to forced sales to escape demurrage charges because of too large shipments, the consequence being cuts in prices ranging from 10 to 25c. There is a good deal of cutting also on bituminous from mines east of Indiana.

Illinois and Indiana bituminous bring \$1.75@2.40 for lump, \$1.60@1.75 for run-of-mine, and \$1.35@1.60 for screenings. Smokeless, as for several weeks, is in much too large supply as regards the lower grade especially, run-of-mine selling for \$2.80@2.95—75@90c. at the mines. Hocking Valley also is weak from overshipments, bringing 10 to 20c. below the circular price of \$3.15 on many sales. Youghiogheny is quoted at \$3.15 for 3/4-in.

gas, and Pittsburg No. 8 at \$2.75 for the same size.

Anthracite is ragged, some dealers having a fair volume of trade in small lots, but no heavy shipments occurring anywhere. There is a general complaint that there is too much coal on hand to be disposed of before spring, unless the unexpected shall happen in the weather.

Cleveland

Feb. 9.—Cold weather and snow have started up the domestic trade to some extent, but with little effect on prices. Steam-coal demand shows very little improvement.

Much interest is taken here in the protest of the Pittsburg operators against irregularities in the rates on coal to Lake ports. They claim that the West Virginia operators have an undue advantage, though their mines are farther from the ports than the Pittsburg district. The question has an important bearing on the Lake coal trade. It is understood that the Pittsburg people will urge an early hearing before the Interstate Commerce Commission.

Indianapolis

Feb. 9.—The advance of 10c. a ton in the freight on coal from the Indiana coal-fields to Chicago has thus far been prevented. The matter has been postponed until next week by the representatives of the several roads interested. The Chicago & Eastern Illinois with its Evansville & Terre Haute connections has a direct route from the mines in western Indiana. Perhaps no other railroad is so well prepared in terminals at the mines and at Chicago to haul coal at the lower rate.

Pittsburg

Feb. 9.—Production of coal at the railroad mines is not more than one-third capacity. But few mines are going in the Panhandle field, the largest producing section in the Pittsburg district. Prices continue on the basis of \$1.15 for mine-run coal at mine and slack is around 70c. Some independents are shading these prices. The rivers are at a coal-boat stage again and over 5,000,000 bu. loaded in coal boats and barges had been brought down from the pools. Most of the tow boats are still down the river and it was impossible to send out more than 1,200,000 bu. today. If the navigable stage continues all will get out this week.

Connellsville Coke—The coke market continues dull and prices for spot shipment are low. A few sales of prompt furnace coke were made yesterday around \$1.00. The majority of the producers are holding firmly for \$1.75 for spot and \$1.90 a 2 on contract. Foundry coke on contract continues firm at \$2.25 a 2, 40, but

for spot as low as \$2 has been done. The *Courier* gives the production in the Connellsville and lower Connellsville fields for the week at 265,514 tons. The shipments were 9663 cars as follows: To Pittsburg district, 3365; to points west of Pittsburg, 5450; to points east of Connellsville, 848 cars.

Foreign Coal Trade

German Coal Production—Production of coal in the German Empire, year ended Dec. 31, metric tons:

	1907.	1908.	Changes.
Coal	143,222,886	148,021,201	I. 5,398,315
Brown coal.....	62,319,802	66,450,144	I. 4,130,342
Total mined...	205,542,688	215,071,345	I. 9,528,657
Coke made.....	21,938,298	21,174,956	D. 763,252
Briquets made...	16,114,478	18,222,667	I. 2,108,189

More than two-thirds of the briquets are made from brown coal, or lignite.

Belgian Coal Trade—Imports and exports of fuel in Belgium, year ended Dec. 31, metric tons:

	Imports.	Exports.	Excess.
Coal.....	4,756,118	5,381,165	Imp. 625,047
Coke.....	1,203,433	376,591	Exp. 826,842
Briquets.....	444,796	105,090	Exp. 279,706
Total.....	6,404,347	5,922,846	Exp. 481,501
Total, 1907.....	6,251,289	5,899,791	Exp. 351,498

The principal exports were to France and Luxemburg; the chief imports from Germany and Great Britain. Exports and imports nearly balance.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on Jan. 30, a slight reduction being shown from the previous report: Best Welsh steam, \$3.42; seconds, \$3.30; thirds, \$3.18; dry coals, \$3.54; best Monmouthshire, \$3.12; seconds, \$3; best small steam, \$2.04; seconds, \$1.74. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, Feb. 10—The iron and steel markets seem to have settled down into a waiting condition. Business remains exceedingly quiet and very few new orders are being placed. In some quarters this is attributed to the tariff agitation; in others the cause given is the general anticipation of a lower range of prices. While both of these have some effect, the expectation of lower prices is undoubtedly the strongest cause of the present situation. In fact, the price discussion is the main topic in the trade, and one hears of very little else.

In pig iron there have been a few transactions in basic iron, but the current business is limited chiefly to the purchase by foundries of iron sufficient for their immediate needs. Judging by what has been done, these are not at all large except in the case of the pipemakers, who seem to have considerable business on hand

Sellers are very reticent about prices, and it is quite probable that a good round order could secure pretty low figures.

The finished-material markets show very little signs of activity, and even the structural market is quieter than it has been. Some building orders continue to be placed, but more seem to be held back. There is no longer any concealment as to the cutting of prices; it is done openly, thus confirming what has been pretty well known for some time. The consequence is, that nearly all current business is going to the independents and smaller concerns. How soon this state of affairs will be recognized is still uncertain, but there is no doubt that it will be met before long.

The Lake Superior Corporation, it is understood, will arrange as soon as the financial plans can be completed for the erection at the Sault of a large blast furnace in addition to the two now in use; one or more open-hearth steel furnaces and a rolling mill to make structural steel, plates and merchant steel.

Pig Iron Production—The reports from the blast furnaces, as collected by the *Iron Age*, show that on Feb. 1 there were 233 coke and anthracite furnaces in blast, having a total weekly capacity of 414,500 tons. This is 12,500 tons more than was reported Jan. 1, and is the largest weekly capacity shown since Nov. 1, 1907. The approximate production of pig iron in January, making allowance for the charcoal furnaces, was 1,821,000 tons.

Birmingham

Feb. 8.—The Southern pig iron and steel market is very quiet. There is but little business being transacted as far as can be learned. There has been no curtailment of the pig iron or steel production as yet. There is a healthy outward movement of pig iron from this district on old orders. It is stated that some of the consumers have halted their shipments a little, but there has been no accumulation of iron. Quotations are given at \$13 per ton No. 2 foundry but rumors prevail of a lower price.

The home consumption is holding up better than in other sections. The cast-iron pipe plants are in full operation.

There has been some depression felt at the steel plant of the Tennessee company at Ensley and rumors prevail that unless there is an immediate improvement in conditions the curtailment will be more pronounced.

Chicago

Feb. 2.—Sales of pig iron continue light and there is no prospect of speedy increase. In general, however, there is probably a slight increase over last week; the disappointment about market conditions comes from the enthusiasts who looked for a boom.

Deliveries in 30 to 60 days are the requirements of the melter in nearly all contracts now being signed. Occasionally a buyer is willing to contract six months ahead and for a requirement of 100 tons or more. But in general he wants a carload to 200 or 300 tons and does not want to dip much into the future.

Prices nominally remain \$17 for Northern and \$13 Birmingham (\$17.35 Chicago) on Southern, No. 2. Any good-sized contract would cut these prices—especially Southern—25 or 50c. a ton.

Iron and steel products are generally quiet. Railroad supplies are more active. Coke is very quiet at \$4.75@4.85 for the best Connellsville with large supplies.

Cleveland

Feb. 9—Vessel men are trying to figure on the movement of iron ore for the coming season, but it is chiefly guesswork. The only thing certain is that it will be light early in the season. The movement from docks is slow, and May will open with large stocks on hand, unless there is an unexpected change. There is talk about ore prices for the season, but nothing has been done yet. The general opinion is that there will be no change from last season.

Pig iron has been dull, with only small orders for quick delivery going. An inquiry for a round tonnage of basic, which was out last week, has been withdrawn.

Finished material is a little better, and some business has materialized in bars and plates, but mainly in small lots.

Philadelphia

Feb. 10—Unfavorable conditions in pig have been emphasized by further shading on the part of some makers without leading to business worthy of mention, except basic, in which a fair business has been quietly done. The business, however, was simply the ordering of material according to previous understanding. Further shading on Virginia and Alabama irons induced some little selling for immediate delivery. A few Pennsylvania furnaces have also shaded 25 to 50c. without inducing consumers to order beyond actual needs. The bar mills continue buying forge for actual necessities. Pipe iron is perhaps better sold up than any other kind.

Steel Billets—While work involving steel billets is gradually increasing there has been a shutting off of inquiries.

Bars—Business has fallen off within a few days, notwithstanding some fractional concessions by a few mills.

Structural Material—No large orders have been placed but there are evidences of considerable business in fabricated material before the end of the month. Requirements for small lots in this territory are increasing.

Scrap—The scrap dealers have allowed some of their stocks to go at concessions, but they claim there is no general cut, and that scrap will bring more money in 30 days. Railroad scrap is held at the shops at figures which forbid buying at present. The lower grades have weakened about 50c., but even at that, very little is taken.

Pittsburg

Feb. 9—Conditions in the iron and steel industry have grown worse rather than better. If anything, the hesitating tendency is more pronounced, and buyers are giving another exhibition of how long they can wait before buying. There is a great deal of talk about price cutting, and some of the large interests, particularly the leading interest, do not hesitate to charge their competitors with cutting quotations on a liberal scale. This is most marked in structural shapes, plates and sheets, but there are also some concessions on a number of other products.

Pig Iron—It is a dull market, showing even less life than a week or two weeks ago. There has been a notable absence even of carload buying. It is stated that consumers are taking deliveries on their old contracts much better than might be expected, but it is admitted that the current consumption, particularly in foundry iron, is not up to the basis called for by contracts on books, and that if consumption does not increase some consumers are likely to begin to ask for postponements. There has been some inquiry for basic iron, but the prospective buyers have not been quoted sufficiently attractive prices, and the deals are held up. Basic is quoted nominally at \$15.50, Valley, bessemer being \$16, Valley, on the basis of recent light sales, although some leading producers quote \$16.50; No. 2 foundry iron is \$15, Valley.

Steel—Deliveries of billets and sheet-lars on old contracts are about the same, while new buying continues light. Prices are well held in this district, two or three eastern and western mills, which would make slight concessions not being able to get into this territory on account of the freight. Billets are \$25, Pittsburg, and sheet-bars \$27.50. Plate specifications continue good on steel-car contracts, this movement being heavier than for many months. In the open market prices are subject to considerable irregularity, particularly on the narrower sizes, but concessions generally do not run more than \$1 to \$2 a ton from the official price of 1.60 cents.

Sheets—There is considerable complaint of cutting in sheet mill products, the deepest cuts being made in corrugated roofing, and running to 10c. a square or more. In flat black and galvanized sheets the cutting is less, while in specialties the

market is fairly well held. Mill operations continue about as formerly, most interests running at about 50 per cent. of capacity, while some are doing better. Official prices are 2.50c. for black and 3.55c. for galvanized sheets, 28 gage, Pittsburg.

Foreign Trade in Iron and Steel

Iron and Steel Exports—Exports of iron and steel, including machinery, from the United States for the year ended Dec. 31, are valued by the Bureau of Statistics of the Department of Commerce and Labor at \$197,066,781 in 1907, and \$151,113,114 in 1908; a decrease of \$45,953,667, or 23.3 per cent. Leading items of export were, in long tons:

	1907.	1908.	Changes.
Pig Iron.....	73,703	46,696	D. 27,007
Billets, ingots & blooms	79,991	112,177	I. 32,186
Bars.....	98,208	52,106	D. 46,103
Rails.....	338,906	196,510	D. 142,496
Sheets and plates.....	122,686	104,993	D. 17,703
Structural steel.....	138,442	116,878	D. 21,564
Wire.....	154,080	136,167	D. 17,913
Nails and spikes.....	56,791	39,906	D. 17,885
Pipe and fittings.....	176,832	114,371	D. 62,461

The total quantities of iron and steel reported were 1,301,979 tons in 1907, and 964,266 tons in 1908; a decrease of 337,703 tons. For some articles, however, only values are given:

Iron and Steel Imports—Imports of iron and steel, including machinery, into the United States for the year ended Dec. 31, were valued at \$38,789,857 in 1907, and \$19,957,261 in 1908; a decrease of \$18,832,596, or 48.5 per cent. The leading articles of import were, in long tons:

	1907.	1908.	Changes.
Pig Iron.....	489,475	92,202	D. 397,273
Scrap.....	27,662	5,990	D. 21,672
Ingots, blooms, etc.....	19,333	12,112	D. 7,221
Bars.....	39,746	19,673	D. 20,074
Wire-rod.....	17,076	11,208	D. 6,868
Tinplates.....	57,773	8,320	I. 547
Sheets and plates.....	3,749	2,629	D. 1,119

The total quantities of iron and steel, so far as reported, were 662,470 long tons in 1907, and 206,955 in 1908; a decrease of 455,575 tons, the greater part of which was in pig iron.

Iron Ore Movement—Exports and imports of iron ore in the United States for the year ended Dec. 31 are reported as follows, in long tons:

	1907.	1908.	Changes.
Exports.....	278,608	309,099	I. 30,491
Imports.....	1,229,168	776,898	D. 452,270

Of the imports in 1908 Cuba furnished 579,608 tons.

Imports of manganese ore were 209,021 tons in 1907, and 178,203 in 1908; a decrease of 30,818 tons.

Foreign Iron Trade

French Blast Furnaces—On Jan. 1 there were 107 furnaces in blast in France; this number comparing with 111 on Jan. 1, 1908, and 112 on July 1 of the same year.

Metal Market

New York, Feb. 10.—The metal markets are still generally quiet and in rather a depressed condition.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Dec. 1908....	\$ 7,358,707	\$ 5,122,538	Exp. \$2,235,169
" 1907....	1,004,441	44,448,615	Imp. 43,444,074
Year 1908....	71,215,456	50,248,099	Exp. 30,969,367
" 1907....	55,216,081	143,398,072	Imp. 88,182,391
Silver:			
Dec. 1908....	4,726,289	4,382,290	Exp. 343,999
" 1907....	4,413,698	4,222,036	191,662
Year 1908....	51,837,671	42,195,966	" 9,640,705
" 1907....	61,025,966	45,912,360	" 15,113,606

Exports from the port of New York, week ended Feb. 6: Gold, \$256,000, to Argentina; silver, \$1,237,680, to London and Paris. Imports: Gold, \$146,763; silver, \$80,964, both from the West Indies, Central and South America.

Gold movement in Germany year ended Dec. 31, reduced to dollars:

	1907.	1908.
Imports.....	\$50,390,000	\$91,028,000
Exports.....	55,450,000	14,185,000

Exports..... Exp.\$5,060,000 Imp.\$76,843,000
The year 1908, therefore, showed a total net gain of \$81,903,000 over the previous year.

The movement of gold and silver through the port of San Francisco for the year ended Dec. 31 was as follows:

	1907.	1908.	Changes.
Gold.....	\$3,506,557	\$4,386,133	1. \$ 879,576
Silver.....	3,336,378	2,724,806	D. 611,572
Exports:			
Gold.....	21,592	20,289	D. 1,112
Silver.....	3,676,656	3,760,240	I. 1,083,634

Gold exports in 1908 included \$1,759,222 coin and \$2,625,911 bullion; silver, \$34,939 coin and \$2,689,867 bullion. Gold exports included \$18,577 coin and \$1093 bullion; silver, \$7829 coin and \$5,752,460 bullion.

Gold—The current price of gold in the open market in London has remained unchanged at 77s. 9d. per oz. for bars and 76s. 4d. for American eagles. The Bank of France seems to be entirely out of the market for the present, and nearly all the gold taken this week went to the Bank of England. No gold was shipped from New York this week to Europe but \$500,000 went out to Argentina on London account.

Platinum—Business is reported very quiet, with sales even fewer than are usual at this season. Prices remain unchanged at \$23.50/24.50 per ounce for refined metal, \$26.50 for hard and \$19/21 for scrap. There is some difference of opinion about the market, and dealers seem to anticipate a slight decline before long.

Silver—The market has ruled fairly steady this week, fluctuating between 51 $\frac{7}{8}$ and 52 $\frac{3}{4}$ c. in New York; and it closes quiet at 23 15/16d. in London.

SILVER AND STEELING EXCHANGE

	Feb.	4	5	6	8	9	10
New York....	52	52	52 $\frac{1}{2}$	52 $\frac{1}{2}$	52 $\frac{1}{2}$	51 $\frac{1}{2}$

30	13 $\frac{1}{2}$	13 $\frac{1}{2}$	58 $\frac{1}{2}$	27 $\frac{1}{2}$	4.00	3.85	4.97 $\frac{1}{2}$

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium. Spelter prices at St. Louis, Feb. 4-10, were 0.15c. below New York.

Copper—The markets on both sides of the water have drifted along listlessly throughout the week. The business placed at the ruling quotations was not sufficient to make much impression one way or the other. Most of the selling agencies are quoting 13 $\frac{1}{2}$ c., delivered, 30 days, equivalent to about 13 $\frac{1}{4}$ c. cash, New York, and are taking business at a little less than that, but no one is aggressive in forcing sales. The close is uncertain at 13 $\frac{1}{4}$ ¢/13 $\frac{1}{2}$ ¢ for Lake copper; 13 $\frac{1}{4}$ ¢/13 $\frac{1}{2}$ ¢ for electrolytic in ingots, cakes and wirebars. The average of the week for casting copper is 12 $\frac{1}{2}$ ¢/13 cents.

Copper sheets, cold-rolled, 20c.; hot-rolled, 19c. per lb., base Copper wire, 15 $\frac{1}{4}$ ¢. base, carload lots at mill.

The London market seems to have reached a state of equilibrium, and fluctuations were narrow throughout the week, with a fairly strong undertone. The close is firm at 50 1s. 3d. for spot, 50 18s. 0d. for three months.

Refined and manufactured sorts we quote: English tough, 463; best selected, 462a/63; strong sheets, 474a/75.

Exports from New York and Philadelphia for the week are reported at 2622 long tons copper. Our special correspondent states the exports from Baltimore at 1142 tons.

Exports of copper sulphate from the United States for the year 1908 are reported at 7,663,882 lb. This carries the equivalent of about 1,015,000 lb. of metallic copper.

The American Smelting and Refining Company and affiliated concerns produced 187,544,000 lb. of refined copper in 1908, against 94,600,000 in 1907, and 85,810,000 in 1906. The Ely production in 1908 was about 12,000,000 lb. About 25,000,000 lb. came from Cerro de Pasco. Production of the Garfield smelter was about 75,000,000, including 43,000,000 from Utah Copper Company and 15,000,000 from Utah Consolidated. The product of the two Utah companies was sold by the United Metals Selling Company; otherwise the Smelting company is now selling its product on its own account.

Tin—The demand which the lower prices brought about from dealers on this side has had its effect on the London market, which became firmer from day to day. Prices advanced in consequence, and the close is cabled at 1128 15s. for spot, 1130 10s. for three months.

The demand in this market, of which mention is made above, emanated principally from dealers, while consumers have not yet taken hold. In sympathy with the London market, prices here have also advanced and the close is firm at about 28 $\frac{1}{2}$ cents.

Lead—The market continues dull and weak. When the American Smelting and Refining Company came out last Friday with the quotation of 4.10 New York, other sellers promptly cut under, and in the absence of a market for the available supply, particularly from Missouri, prices have eased off still further, and the close is weak at 4@4.05c., New York.

The market in London is firmer, the close being cabled as 113 1s. 3d. for Spanish lead, 113 3s. 0d. for English lead.

Spelter—Absence of buying on the part of galvanizers and brass manufacturers, on the one hand, and the sharp break in the Joliet ore market, on the other, have made sellers very anxious to dispose of their metal, and in their efforts to find a market, prices have slipped away from day to day so that the market is bordering on demoralization at the close, which is quoted at 4.72 $\frac{1}{2}$ ¢/4.75c. St. Louis, 4.87 $\frac{1}{2}$ ¢/4.90c. New York.

The close in London is cabled as 421 5s. for good ordinaries, 421 10s. for specials.

Base price of sheet zinc is 7c., f.o.b. La Salle-Peru, Ill., less 8 per cent

Other Metals

Antimony—The market is exceedingly quiet with sales only of a retail character. There is no change in prices, which continue nominal at 8½@8¼c. for Hallett's; 8@8¼c. for Cookson's; 7½@7¾c. for ordinary brands.

Aluminum—Offers of foreign metal are still heard of at 22c., and even lower, but it is difficult to trace actual sales. Efforts are being made abroad to secure a new agreement among manufacturers, but so far without success. The Aluminum Company of America continues to quote 24c. base for No. 1 ingots; 33@34c. base for sheets.

Quicksilver—New York quotations are still \$45@40 per flask of 75 lb. Business is dull, with few sales. San Francisco quotations are nominal at \$45@46 for domestic orders, with \$2 less for export. The London quotation is £8 7s. 6d. per flask, with £8 6s. 3d. named by jobbers.

Nickel—Large lots, contract business, 40@45c. per lb. Retail, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. These quotations are for spot nickel. The price for electrolytic is 5c. higher.

Cadmium—In 100-lb. lots, 75c. per lb., at Cleveland, Ohio.

Magnesium—This metal is offered in New York at \$1.25 per lb. in 100-lb. lots. The price is \$1.40 per lb. for 5-lb. lots.

Zinc and Lead Ore Markets

Platteville, Wis., Feb. 6—The base price paid for 60 per cent. zinc ore this week was \$38@40 per ton; no premium is reported paid. For 80 per cent. lead ore, \$50 per ton was paid.

SHIPMENTS, WEEK ENDED FEB. 6

Camps.	Zinc Ore, lb.	Lead Sulphur ore, lb.	Sulphur ore, lb.
Platteville.....	97,240		389,000
Benton.....	573,250

Reway.....		60,000	
Total.....	2,849,500	142,800	389,000
Year to Feb. 6.....	11,165,206	202,800	1,101,400

Highland, Linden, Harker and Mineral Point are not reported. The shipments given above are for two weeks, the report for the preceding week having been omitted. There was shipped during the last two weeks to the American Zinc Ore Separating Company, 332,800 lb. and to the Joplin Separator Works, 332,700 lb. zinc concentrates.

Joplin, Mo., Feb. 6—The highest price paid for zinc sulphide ore was \$40.50, the assay base ranging from \$38 down to \$36 per ton of 60-per cent. zinc, coarse ore, with slimes sold on a \$34 base price. As high as \$24.50 was paid for zinc silicate, the base per ton of 40-per cent. zinc

ranging from \$19 to \$22. The average price, all grades of zinc, was \$35.10 per ton. The highest price for lead ore was \$54 per ton, for settlements on ore purchased the previous week, but the high offering of this week was \$53, ranging down at the week-end to \$52. The average price, all grades of lead ore was \$51.95 per ton. Lead ore is now being largely sold on a basis per ton of 80-per cent. lead. Considerable ore in the district will run this high, a little over 80 per cent., and the district will average very close to the base.

Sharp falls have prevailed in the price of zinc ore during the past three weeks, aggregating \$6 per ton. Some mines have shut down, nearly all have reduced wages, and it is rumored that others will close down soon, unless there is an upward change in zinc prices. The producers lay it on the decision admitting calamine free of duty, and the smelters charge it onto the tariff agitation, which keeps spelter consumers from contracting ahead for metal.

NOTE—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore. The second two the average for all ores sold. Lead ore prices are the average for all ores sold.

Chemicals

New York, Feb. 10—The same lack of animation in trade conditions that has existed for several weeks still prevails.

Copper Sulphate—Demand is fair and

conditions unchanged. Quotations are steady at \$4.75 per 100 lb. for carload lots and up to \$5@5.50 per 100 lb. for smaller parcels.

Arsenic—The market is dull with few sales, and prices are a little lower. Quotations current are 3@3½c. for white arsenic; 2.90c. per lb. for Canadian.

Nitrate of Soda—Statistics of nitrate in the United States Feb. 1 are reported as below, in long tons, by Mortimer & Wisner, New York:

	1907.	1908.	Changes.
Stocks, Jan. 1.....	5,800	9,140	I. 3,240
Imports for month.....	25,800	14,800	D. 11,000
Total Supplies.....	31,700	23,940	D. 7,760
Deliveries for month.....	28,945	18,890	D. 10,055
Stocks, Feb. 1.....	2,755	6,050	I. 2,295
Afloat for U. S.	70,600	99,300	I. 29,300

Quantities afloat include all cargoes due to arrive at United States ports by May 15 next.

Trade is fair. Current quotations, however, are a little lower, spot selling for 2.15c., with 2.12½c. asked for futures.

Phosphates—Exports of phosphate rock through the port of Savannah in December are reported by J. M. Lang & Co. as follows: Italy, 1685; Germany, 5165; total, 6850 long tons.

Mining Stocks

New York, Feb. 10—The general stock markets have been rather inactive during the week, but prices have been fairly well maintained, on the moderate amount of business done. Some special strength was developed in American Smelting and Refining, on the publication of the semi-annual statement.

On the Curb also transactions were not on a large scale, but prices were generally well sustained. Ohio Copper was the leader among the copper stocks, and rather liberal selling failed to break the quotation more than a fraction. Dealings in the Cobalt stocks were on a fair scale. The Nevada gold stocks were quiet, as a rule.

Boston, Feb. 9—The so-called Bigelow stocks have been the local features the past week. The drop in the price of copper had a temporary depressing effect in mining stocks, but this in a measure, had been discounted. The air has been full of rumors of a settlement between the Calumet & Hecla and Bigelow people, but nothing definite has yet transpired, although it is believed that some agreement will be reached. At one time the matter of \$200,000 was said to be the only difference in an amount said to involve \$8,000,000 at least.

Isle Royale benefited by rumors that in the case of a settlement this company would also come into the agreement. The Bigelow interests are believed to have a greater ownership in this property than any of the others. The stock, on heavy

trading, -spurted from \$26.25 to \$30. The final tonight was \$28.75. North Butte has been persistently offered and the price fell from \$70.25 to \$73.45 with substantial recovery. Alouez rose \$3.25 to \$41, losing partially, and Centennial touched \$33.75.

East Butte has come in for a share of popularity and the price rose sharply from \$8.5 to \$12. Good reports are coming in from the mine. Adventure rose \$1 to \$9, but lost it, and Atlantic advanced \$1.25 to \$16. Boston & Corbin is up \$1.50 to \$20.62½, and Franklin rose \$1.50 to \$16.50, with subsequent setback. Over 60,000 shares of Rhode Island stock have been deposited under the plan of taking it over by the Franklin, one of the latter for three Rhode Island. Osceola -spurted \$4.50 to \$134.50, but did not hold it, and Tamarack rose from \$75 to \$83, losing \$3 of it.

American Zinc has taken on activity and the stock has advanced \$4.25 to \$27.75. United States Coal and Oil sold up \$2.62½ to \$31.62½. This company made its largest shipment of coal in its history during January—128,000 tons. Amalgamated has held from about \$75 to \$76 during the week and Copper Range from \$78.50 to \$73.50.

The Winona Copper Company has leveled a \$1 assessment, payable March 9 for the purpose of continuing development. This will make \$17 paid in to date.

On the Curb Raven broke 20 to 59c. Stockholders did not subscribe for the stock offered at \$1 in sufficient amount, and the mine has been closed down.

Industrials

The Hammond Iron Works, Warren, Penn., has established an office at 5 de Mayo 32, Room 222, Mexico, D. F., in charge of Francis E. Pratt, recently of New York.

The Wellman-Seaver Morgan Company has just made arrangements for F. H. Boswick, of Denver, Colo., to represent it in the western field. He will be the manager of the western office, located at 611 Ideal building, Denver, Colo.

Charles T. Malcolmson has recently accepted a situation with the Roberts & Schaefer Co., Old Colony building, Chicago, Illinois. He will have charge of its recently organized briquetting department. With the added facilities which his new connection offers for designing and building this class of structures, we may look forward to some very interesting results in the briquetting of coal and lignites.

Warren Wood, of the Wood Drill Works, Paterson, N. J., and Robert J. Wood, manager of the Chicago branch, will leave the United States on February 19 for a three weeks' visit to the Panama canal zone for the purpose of inspecting the work done by Wood rock drills, and upon their return the Wood Drill Works will publish a booklet containing valuable cost data and comparisons, with some interesting views along the canal.

The large order for the complete fuel equipment of the Coronet Phosphate Company, of Coronet, Florida, has been awarded to the Tate, Jones & Co., Inc., Pittsburg, Penn. It consists of the celebrated "Kirkwood" oil system, comprising burners, pumping, heating and regulating equipment, etc. The great economy of oil (by the Tate, Jones method) over the other fuels, together with its simplicity and perfect control at all times, led to the placing of this contract with the Pittsburg concern.

The Deming Company, Salem, Ohio, has issued a handsome catalog giving full details of its spray pumps, nozzles and appliances. The catalog contains a very complete 12-page spraying chart; also shows sectional and detail views of several of the pumps, and illustrates many of them in action. It is printed in two colors, with shaded illustrations, making a very fine appearance. The Deming Company also manufactures a very complete line of hand and wind-mill pumps, hydraulic rams and triplex and deep-well power pumps for various duties and for operation by any power. Interesting literature will be sent to any parties desiring information on Deming pumps.

The Northern Electrical Manufacturing Company, Madison, Wis., announces the enlargement and removal of its St. Paul district office to 1046 Security Bank building, Minneapolis, Minn. This betterment of its sales office facilitates closer relation with its valued customers in the twin cities and improves its office surroundings. T. E. Drohan, who has been representing the company in the St. Paul office, will continue in charge of the Minneapolis office. His experience as superintendent of the Northern works makes it possible for him to serve customers in his territory to excellent advantage, as his sales interest is coupled with an intimate knowledge of manufacture and design.

The Wagner Electric Manufacturing Company has placed on the market a portable polypphase wattmeter, which gives in a single indication the total power consumed in two-phase or three-phase circuits, or the power consumed in a single phase. This instrument has the same accuracy on an unbalanced as on a balanced circuit. The Wagner line of switchboard, and portable instruments is said to be the most complete that the American market affords, including ammeters, voltmeters, wattmeters, power-factor indicators, frequency meters, ground detectors and synchronism indicators, together with current and potential transformers for all capacities, voltages and frequencies and any character of service.

The Burnite Machinery Company, with Thos. B. Burnite as manager, has succeeded the Burnite-Leonard Engineering Company, of Denver, Colo. The company has moved into a more commodious office and store room at 17th and Glenarm streets and is nicely fitted up. Mr. Burnite has been a machinery man all his life, having been connected with the engineering department and shops of several well known concerns. He has been identified with Colorado machinery interests for the past three years. The company represents the Hardscog Wonder Drill Company, the Erie City Iron Works, the Bury Compressor Company, the Krogh Centrifugal Pump Company and various other lines, making a complete equipment for mine, mill or power plants of all descriptions. A large line of Hardscog wonder drills and accessories are carried in stock for immediate delivery, the smaller sizes of Bury compressors and Erie boilers will also be carried, as well as a line of Krogh centrifugal pumps. The company is equipped to design, furnish and install mining, milling, power and pumping plants complete.

The Dayton Globe Iron Works Company, Dayton, Ohio, has issued an 80-page catalog describing and illustrating the New American turbine. It is printed on 100-lb. high grade coated paper, which brings out every detail of the many half-tone illustrations. The cover is of dark gray stock with a light gray flyleaf, and is highly embossed with the company's name and the name of the product. A very pleasing effect is obtained by the use of a tint block in a delicate shade which overcomes the high gloss of the paper stock and makes the illustrations more attractive by having the high lights cut away and bringing them out in white. Not only the tables of power of the various types of New American turbines but other tables of value to those interested in water power development are contained in this book. Taking all points into consideration it is undoubtedly one of the most attractive and valuable catalogs yet issued for the water-wheel trade and speaks very well of the business methods which have made the Dayton Globe Iron Works Company one of the foremost manufacturers of water-power equipment.

The Western Electric Company has recently designed a magneto telephone set for satisfactorily meeting the most exacting requirements of mine telephone service above ground. Anyone who has had to do with mining operations knows how important it is that mine telephone sets must be constructed so as to render the most efficient and reliable service under the most exacting conditions and with the lowest maintenance expense. These newly designed telephone sets are very compact and reliable, and the woodwork and all the working parts are constructed of the very best materials. Each part of the equipment is mounted so as to be readily accessible. Each set is complete and ready for use with the exception of the dry cells. The battery compartment is large enough to hold three standard size dry cells. A writing shelf mounted below the transmitter is convenient in making notes of orders received over wire. Improved Blue Bell dry cells are specially recommended for mining telephone work. Tests have shown them to have long life and high efficiency. A special feature of these magneto telephone sets is the location of the main binding posts inside the cabinet. This prevents trouble from tampering with the connections and accidentally short-circuiting a set at the main terminals. All the binding posts are fitted with screw connections. The permanent connections are soldered and terminals attached to flexible leads are provided for the battery. All apparatus in these sets is of standard Western Electric quality, the same quality which has been maintained by this company for over thirty years for local and long distance telephone work. Equipment of good quality with ordinary care means low maintenance charges and low maintenance charges are as important in a small mining telephone system as in a large one.

The problem of mine pumping is so vitally important and so difficult to solve satisfactorily that it requires the most careful consideration on the part of mining engineers, and special pumps must be designed by experts who have had many years' experience in this field. The Jeannette Iron Works Company, being located in the heart of the anthracite coalfields and therefore having the benefit of a vast and varied experience in the territory where the pumping problem is the most complex, has justly earned the name of being one of the foremost and most expert manufacturers of mine pumping machinery in the country. Its shops, which were originally located in Jeannette, Penn., were moved in 1904 into new buildings situated at Hazleton, Penn., and equipped with modern machinery and appliances. Its specialty is heavy mine pumping machinery, and although it has suffered somewhat from the business depression, it has never been entirely idle, and is reported to be running day and night at the present time in order to meet the demand for a number of large mine and water-works pumps that are promised for quick delivery. The company does not confine itself to the manufacture of mine pumps exclusively, but is branching out into other directions. A seven-million gallon crank-and-flywheel pumping engine for South Bethlehem, Penn., has just been completed and is pronounced by the testing engineer to be a most economical pumping engine of this type. Two large mine pumps have been shipped to the Leon Mining Company, of Mexico, for its gold mine and are now being installed. Three large compound mine pumps of 36-in. stroke are under construction for the coal mines owned by the Delaware, Lackawanna and Western Railroad Company, and also one triple-expansion engine of 48-in. stroke for the same party. This is claimed to be the largest pumping engine for mine service ever contracted for. The lift is 1000 ft. and the capacity from 2000 to 3000 gal. per min. In addition to these, many smaller pumps are being built, as well as a number of turbine pumps of the company's improved multi-stage type. The company is now competing for the pumps required in the phosphate mines of Florida, and has been successful in securing contracts for the most up-to-date pumping plants.

NO. 8.

An Ore-handling Plant in New Caledonia

An Elaborate System of Suspension Tracks and Cables, Comprising Four Main Lines, for Carrying Ore, Coal, Merchandise and Passengers

SPECIAL CORRESPONDENCE

The development of the ore resources of the island of New Caledonia has hitherto suffered severely from the lack of suitable transportation and handling facilities between the sea and shore. Owing to the rocky and treacherous nature of the coast, approach is difficult, the difficulty being accentuated by the heavy surf which prevails. Such conditions militated against

trade, more especially so since vessels of heavier tonnage were precluded from securing consignments of this freight for their return voyage to Europe.

Under these circumstances the mining interests concerned decided to lay down a complete modern plant replete with every facility and convenience for the expeditious handling between ship and shore not

vessels, and to connect this isolated landing stage with the mainland by means of a wire ropeway, over which the whole of the traffic between the ship and shore would travel.

Such an arrangement offered complete independence of the state of the tide, currents, rocky character of the shore; and the contemplated site, being sheltered by

ROPEWAY FROM CENTRAL STATION TO LOADING BRIDGE

vessels, except those of the small, and shallow-draft coastal type, and prevented their coming sufficiently near the mainland to ship the ore from the barges which brought it from a small jetty, through the surf. Such methods, being not only tedious and slow but expensive as well, handicapped the expansion of the export

only of the ore but also miscellaneous freight such as stores, coal, and even passenger traffic. As a solution of the problem Adolf Bleichert & Co., of Leipzig, Germany, suggested the construction of a large landing stage about 1000 yd. from the shore provided with every appliance for the rapid discharging and loading of

a peninsula jutting into the sea, offered complete protection from storms, thereby enabling even the largest vessels that would call at the island to ride in perfect safety and beyond the surf. The construction of such a landing stage, as the engineers pointed out, offered no insuperable difficulties, while the necessary piers

for supporting the ropeway required only a small base width, so that they would offer only the minimum of resistance to currents which might lead to the accumulation of silt, while the carrying ropes could be carried at such a height as to be beyond the reach of the waves during the heaviest storms.

REQUIREMENTS OF THE SYSTEM

Under these circumstances the mining authorities decided upon this system and the contract was placed with the firm named at the end of 1902. In this decision not only were the mining interests impressed by the lower cost and the expedition with which such a project could be consummated with complete satisfaction, so far as their requirements were concerned, but it entailed the readjustment of their existing facilities on the island to the minimum. Such a cableway accommodated itself easily to the conditions prevailing.

such as was required at the dumps. A bank 65 ft. high was contemplated in order to carry large stocks of ore, and as in any event this phase of operations would have necessitated the construction of an aerial cableway, it was realized that considerable saving in time and expense would attend a complete rope-driven suspension railroad over the whole district to be served, and it offered the further advantage that the varying differences in level could be more easily negotiated by the guide-driven ropeway and would enable the working of the whole to a very great extent to be carried out with an automatic drive.

A comprehensive idea of the varied and heavy nature of the work which this cableway was designed to perform may be gathered from the following:

- (a) Discharge of ballast or coal from arriving vessels.
- (b) Discharge of ore from small steamers arriving from contiguous islands.
- (c) Filling ore brought from vessels at the seaboard dumps.

terminus of the existing railroad coming from Bornet. At this point the road runs with a moderate gradient up a bank to such a height that by opening the bottom traps of the cars the contents can be shot into huge hoppers, underneath which is situated the terminus of the overhead cable railroad, so that the hoppers can be discharged quickly and easily as rapidly as they are filled from the railroad cars.

The cableway system is divided into four sections, each of which performs a distinct function, though all effect a junction at the central station. Line No. 1 is that which handles the ore between the railroad stations and the ore dumps. Immediately upon receiving its charge of ore at the railroad-station hoppers the car is carried over lofty steel supports to a return station where it turns automatically and returns toward its starting point where the ore dumps are placed. In order to negotiate this section the line makes a sharp ascent in order to give the requisite

DRIVING STATION WITH COAL DEPOT

CENTRAL STATION, SHOWING SWITCHES AND CROSSINGS

The mines are situated on the Thio plateau and the ores are transported from Bornet to the seaboard station at Mission bay over a surface railroad. The drop to the shore, however, is somewhat rapid and steep, and to continue the railroad from its existing terminus to a point where it was decided to establish ore stock dumps would have been impossible owing to the heavy nature of the grades while breaking bulk, and transference to other types of transport would have been too expensive. At the same time the supplies of ore thus brought down by the railroad to the stock dumps are supplemented by cargoes from the neighboring islands carried in small coastal vessels. These latter had to discharge into lighters which brought the ore to the shore, whence it was carried to the dumps, a similar process having to be repeated in loading these vessels with coal and stores.

Again the configuration of the country prevented the formation of a high tip

- (d) Removing and storing sand brought as ballast on incoming ships.
- (e) Transfer of coal from incoming vessels to seaboard coal depot.
- (f) Transportation of ore arriving from up-country per railroad from terminus of latter to the dumps.
- (g) Transfer and load ore arriving from inland vessels moored at the landing stage.
- (h) Remove ore from dumps to vessels at landing stage.
- (i) Transport coal from depot to bunkers of incoming vessels.
- (j) Negotiate all passenger and other traffic between vessels and shore.

The heaviest and most important work, however, is that under *g* and *h*, which occurs every day.

PLAN OF THE INSTALLATION

In view of the fact that the whole plant was to be carried out as a rope-driven suspension railroad, it was decided, owing to the advantages offered, to establish a central station at a suitable point, whence all the lines for the various operations could be converged and the driving movements could be controlled and directed. Selection fell upon a small area close to the sea, and in close proximity to the

height for the formation of the dump. As the car passes over this latter it is caught by a movable adjustment appliance which tips the car without arresting its forward progress and the contents are discharged upon the dump beneath without the slightest interruption of the traffic.

Considering the fact that the dumps are intended to attain a size of 50,000 tons, it is necessary to tip to a height of 65 ft., so that the towers or supports carrying the overhead railroad, and having a height of 80 ft. will be buried in the ore up to the level of the protection rollers of the carrying ropes. In order that these supports may not suffer any damage from the falling ore by the pressure from the bank becoming higher on one side than the other, or its integral parts becoming blocked with the mineral, the usual profile in iron design is superseded by a cone-shaped support of sheet steel which affords a higher factor of stability and rigidity.

Consignments of ore, intended to be transported direct from the railroad cars to the ships moored outside the landing stage, are also carried over this line and to line No. 2, the section connecting the landing stage with the mainland, the cars discharging their contents upon arrival at the landing stage into traveling hoppers, from which in turn the buckets of the loading cranes are filled and emptied into the vessel's hold, the cableway cars turning automatically and running back to the central station. Line No. 1 has a carrying capacity of 40 tons per hour. The cars are spaced 390 ft. apart, and have a traveling velocity of $6\frac{1}{2}$ ft. per second.

CABLE LINES OF THE SYSTEM

Line No. 2, which is the most important of the whole system, inasmuch as it connects the landing stage with the mainland, is about 1000 yd. long, and effects a junction at the central station with the other three sections. Its duty is somewhat heavy, and for this reason its hand-

per hour, with a car speed of $6\frac{1}{2}$ ft. per second and with the cars spaced $175\frac{1}{2}$ ft. apart.

This line serves a variety of purposes. The northern stretch serves on the one hand to form the connection between the "taking-up" line and the sea, and on the other hand the connection between the coal depot and the sea. At the same time at a point, about midway in this northern stretch above the three side tracks of the railroad which the line crosses, there is a large hopper for the accommodation of sand ballast transferred from incoming ships. This sand is loaded from the vessel by grabs, dumped into cableway cars which convey it over line No. 2 to the central station, where it is taken up and dumped.

The sand is in turn discharged from these hoppers into railroad cars and used for building up railroad embankments, or for filling depressions in the ground. This arrangement has the advantage that on one side of the line supplies of ore can be

it into the crane hoppers. The coal-laden cars travel back to the coal depot, deliver their contents, are pushed over from line No. 3 to line No. 4, which extends along the ore dump, recharged, pushed back again off line No. 4 to line No. 3 and sent back to the ship.

Line No. 4 is a low-level section, and its function is to convey ore from the dumps to line No. 3 for transportation to the landing stage, thereby supplementing the through direct line between the railroad and the sea stations. It is a double-roped-driven line and extends along the ore dump at the low height of $6\frac{1}{2}$ ft., connecting with a traveling cross-bridge spanning the whole dump and also carried at a height similar to that of the cableway in conjunction with which it works.

On this traveling bridge are two hoppers from which the cars of the cableway are filled, and these hoppers in turn are charged by two cup elevators running along the dumping site on a track. In the area of the dump, however, are the

LOADING CRANES IN THE HARBOR

SAND HOPPER AT CROSSING OVER SURFACE LINE

ling capacity is considerably increased in comparison with the other stretches; it can deal with 100 tons per hour in either direction. The car speed is the same, $6\frac{1}{2}$ ft. per sec., but the cars are spaced only $175\frac{1}{2}$ ft. apart. Over this line all traffic between ship and shore, irrespective of character, is maintained.

Line No. 3 conveys ore from the dumps over line No. 4 to the central station or landing stage, coal and sand from the central station to the coal depot and sand hopper, respectively. This line is laid at a great height, for not only has it to cross line No. 4, but also three surface-railroad tracks extending between the central station and the ore dumps. As it approaches the central station it descends sufficiently to come level with line No. 1. Indeed, the whole system is designed so that at this point the four sections are at a uniform level, to facilitate handling and switching, approximately 8 ft. above the ground. Its handling capacity is 100 tons

obtained for conveyance to waiting vessels, while ballast can be brought back on the return trip. Consequently, the cars need not return empty, and both sides of the cable way are thus turned to profitable account. Again, the whole of the coal traffic is maintained over this section. The coal unloaded from the incoming vessel is despatched over the sea section, or line No. 2 to the central station, switched on at that point to line No. 3, whence it is carried to an angle station, pushed upon the southern stretch of this section and sent to the coal depot into which it is discharged automatically without stopping the car, the latter then returning to the ship.

METHOD OF OPERATION

In handling coal two operations can be carried out at the same time. A steamer discharges this freight into the cars which have brought their consignments of ore out to the landing stage and discharged

two conical steel towers supporting line No. 1, and in order that the cross-bridge may not be obstructed in its operation, it is constructed in two separate parts connected in the center by swing rails. In passing one of the towers the cross-bridge is divided by swinging these connecting rails outward and the parts thus pass the obstruction separately, being reconnected upon the other side. If necessary the bridge can be used at half-length in order to pick up the ore near the supports, at least on one side, there being a return rail in the center of the cross-bridge for this purpose.

The cars are pushed over the bridge by hand; at the extremity is a coupling joint where the cars are attached to the traction rope of the cableway. The cars, charged with ore by the cup elevator, run along the dump on the inner side of the framework carrying the cableway to a return station and then toward the center of the cableway framework. From the pre-

vailing low level the line now has a sharp upward grade continuing until a height of about 33 ft. is gained at the junction and angle station, which branches off on one side to the central station and thence to line No. 2 through switches and cross-overs; on the other side it goes to the coal depot which is of 1500 tons capacity. The cars have now reached the level of line No. 3 upon which they are pushed by hand, run over this section to its junction with line No. 2 and thence direct out to the sea station. This fourth line has also a handling capacity of 100 tons per hour, but the car speed is increased to 26 ft. per second while the spaces between the cars is reduced to $7\frac{1}{2}$ feet.

For the sea section of the line and that extending over the ore dumps the track is of locked carrying-ropes of long span. Over the ore dumps the spans are consecutively 195 ft., $227\frac{1}{2}$ ft., 179 ft. and $162\frac{1}{2}$ ft.; on the sea section the spans are 390 feet.

come by the utilization of the Bleichert automatic gripping apparatus with under-hung rope which admits gradients up to 45 deg. and at the same time is absolutely unaffected by any variations in the diameter of the rope arising from the causes named.

The work of erection offered no serious difficulties. The only precautions necessary were in connection with the construction of the more elevated portions of the ironwork against the severe storms and typhoons common in the locality. In regard to the sea section, however, constructional work was of a more difficult character. The sea bed is of a varying nature being rocky and level close inshore giving way to silt farther out and offering no stable foundation. For the former sites suitable rocky ridges were selected and upon these cement piers were built to high-water level with the usual type of iron profile towers constituting the superstructure for carrying the cableway.

air-lock could not be undertaken, since a single storm would have sufficed for the complete destruction of this preliminary work. Moreover, the nature of the sea bed was but indifferently known. Consequently it was decided to build huge caissons or tuns on land for inclosing the masonry work, and then to take them out to sea and sink them in the desired position.

At first, however, the sites were extensively dredged to remove the upper layer of mud and silt, and to gain access to the underlying gravel for a firm foundation. These areas were then covered with large stones to a depth of about 17 ft. to protect the sites from becoming covered with silt and partly to afford a suitable foundation for the caissons.

The design of caisson adopted comprised two timber cylinders, one inserted within the other. The inner was of $32\frac{1}{2}$ ft. and the outer of 45 ft. diameter, leaving an annular space $6\frac{1}{2}$ ft. wide to be provided with a substantial flooring. These

RETURN AND TENSION STATION, LINE NO. 1

ANGLE AND JUNCTION STATION

DIFFICULTIES OF CONSTRUCTION

In laying out the cableway the number of curve returns that had to be dealt with constituted an important feature. It was imperative that they should be negotiated automatically without detaching the cars from the traction rope, as this would have caused interruptions in traffic owing to the comparatively rapid sequence of the cars. Further, although there are four different traction ropes for various purposes it was essential that they should work together in such a manner as to enable the cars to be switched over from one line to the other without any difficulty.

With four different traction ropes subject to varying tensions the difficulties of the problem may be realized, especially as the disadvantage of different rope diameters due to differences in strain have to be neutralized. All the traction ropes are of the same diameter, but this does not remain constant; the shrinkage in diameter aggregates as much as 27 per cent. after prolonged use, according to the strain imposed. This difficulty was over-

come by sand was encountered piles were driven and strengthened by concrete, this work being carried out by divers, and the whole finally covered with heavy stones. Upon this mass an iron frame was built supporting a platform above water upon which was placed the iron supporting towers about 49 ft. high. This part of the work completed, the cables were soon placed in position.

LANDING STAGE

The construction of the landing stage comprised the most difficult part of the whole undertaking. It was imperative that it should be placed sufficiently far out to sea to provide a minimum depth of 33 ft. of water, so that vessels could come, moor and go at any state of the tide. The most serious part of the work was in connection with the piers for carrying the superstructure. The strong currents, the rough character of the sea, and the muddy water prevented submarine building by divers, while similarly piling by means of an

cylinders were built on shore. The floor was first laid and to this the iron frame around which the planks were to be secured was placed in position. The planking was erected in the same way as the staves of a barrel with iron rings of U-shape pointing upward. Finally the cylinders were rendered water-tight with roof-felting and tarred sail-cloth. Upon completion they were launched, towed out to the site, and sunk into position by the simple admission of water. Despite the numerous difficulties that had to be overcome in connection with this part of the work, it was rapidly and successfully accomplished, and the masonry was soon filled in and completed ready for the superstructure.

The landing stage is built in two sections, the outer extremities resting on the outer piers and meeting on the central pier. Each section is 114 ft. long giving a total length from end to end of 228 ft. The clear span length of each section is 90 ft. Again each section consists of two main carriers with parallel bracing of

simple construction with a height of 9 ft. 9 in. The main carriers are spaced 36 ft. from one another. The lower chord of these main carriers is of angle iron with intermediate riveted vertical steel sheets, and the upper chord is composed of two U-irons with the webs turned to each other; the upper flanges with the help of cross-irons serve to take up the rails for the traveling cranes.

On the middle pier the landing-stage sections have their extremities on a fixed bearing, the two outer piers carrying suitable roller bearings to allow necessary play. The cross bracings of the landing stage also consist of parallel girder carriers above which are the bracings for the working platform and the cableway. These are also longitudinally strutted with U-irons, the longitudinal U-iron binding together the top cross U-irons also forming the main girder for taking up the cableway shoes.

The working platform is 6½ ft. above the upper chord of the main carriers along which a second platform 3¼ ft. wide extends, but which is intended only for attendance on the traveling drive of the cranes. On the side facing the shore the landing stage has an extension somewhat resembling a balcony joining the main structure at an obtuse angle and which carries the saddles for the carrying ropes of the cableway as also the tension-weight rollers, the weights hanging in a recess in the pier. The saddles of the carrying rope are faced on the sides with cast-steel plates at the point where they transfer the traffic to the fixed overhead rails of the landing stage in order to protect the carrying ropes from damage as they are particularly subject to wear and tear at the deflection points owing to the passage of the cars. The carrying ropes from the shore to the landing stage are firmly anchored in the central station and stretched by weights on the landing stage with the aid of flat strand tension ropes running over large cast-iron tension rollers.

THE CRANES

The two cranes are of the double-jib type with raising jibs and with two rope trolleys which permit hoisting and lowering as well as stopping at any point of the track. Both cranes span the superstructure of the bracing of the landing stage on which the cableway is carried. Just over the superstructure is the engine house providing the power for the cranes complete with steam engine and boiler. It was decided to be more satisfactory to select an independent steam drive on the landing stage for its own requirements since, although electric operation would have been possible, the expense of laying a cable for the purpose from the shore was considered too heavy, while at the same time any breakdown at the electric generating station would paralyze loading and unloading on the landing stage.

Owing to the exposed position of the cranes (they travel on a track 162½ ft. in length, while the jibs when raised are nearly 100 ft. above the water level) it was necessary to secure a high factor of stability, especially when the heavy wind pressure incidental to the heavy storms and typhoons is borne in mind. The wheel base of each crane is 32½ ft., while the width of the engines houses is 16 ft. For further protection against storms the cranes can be brought up side by side and anchored together forming one complete structure with an extensive ground area. The outer parts of the jibs can be raised for a length of 40 ft. to enable ships to moor alongside without recourse to cross-towing.

The cranes can be worked with both grabs and buckets. A so-called drum-grab has been selected, the closing chain winding on the drum axle while the hoisting chain unrolls from the drum in tightening. The gearing lies in the difference between the diameters of the drum-axle and the drum. These grabs have the advantage that they can be quickly changed for buckets without taking out the hoisting ropes, a point of no little importance as frequent changes from grabs to bucket and *vice versa* are necessary.

The trolley, which carries the grabs and buckets and which can traverse the whole track, is driven by the triple-drum winch coupled direct to the steam engine. The trolley traveling rope coming from one of the two traveling drums, which are free on the main winch axle, is fastened at its end on one side of the trolley. On the other side of the trolley the end of the rope going to the second traveling drum is fastened. This rope coming from the trolley first winds around a roller on the extreme end of the jib and thence passes to the opposite jib point. It here lies on a return roller from which it goes to the second traveling drum. The hoisting rope for hoisting and lowering the grabs or buckets is made double to procure a smaller diameter. At the extremity of the jib it is fastened with a spring buffer, runs downward over a return roller in the trolley, winds round the double-riveted steel block, which carries the bucket or grab, and then passes over the second return roller of the trolley to the extremity of the opposite jib. Here it is again wound around a return sheave whence it passes to the hoisting drum provided with symmetrical grooves running in opposite directions. The two traveling and the hoisting drums are mounted on the main winch shaft with which they are connected by friction couplings, the latter being provided with band brakes.

DETAILS OF OPERATION

For raising the jib two winches are built in above the engine house driven by the steam engine of the main winch by Ewart driving chains. From the winches

by means of special guide rollers the wire ropes pass over the end of the fixed jib frame to the extremity of the movable jib which is held in its level position by joint rods.

The steam engine is of the non-reversible twin type, hoisting, lowering, and reversal of the trolley traveling movement being effected by suitable motions of the drums assisted by band friction couplings. Steam is raised by a fire-tube boiler, and the water is brought from the shore in special cableway cars.

Each crane is fitted with four hoppers and charging funnels, one of the latter being built in on each side of the crane at the height of the working bridge. The cableway cars arriving from the shore with ore, dump their contents into these funnels, while beneath the latter are chutes through which the ore gravitates and fills the buckets of the crane, there being flaps in the chutes operated from the engine house controlling the delivery into the buckets.

For discharging vessels there is a further hopper built on each side of the crane on the level of the engine-house platform into which the buckets or grabs discharge their contents. At the bottom of these hoppers is a funnel which conveys the material into the cableway cars below and in such a manner that the cars can be filled without difficulty from the inner side. On the landing stage there are several short sidetracks and switches radiating from the main cableway system, so that it is not necessary for the cars to traverse the whole length of the landing stage. The suspension rails in the upper parts of frame are hung directly by means of cast-iron shoes on the cross braces of the bridge carrier, the chords being made to project for this purpose.

Owing to the design of the plant it is always possible to carry out several operations simultaneously. Two ships can be loaded or unloaded at the same time, one on each side, while one can be loaded as the other is being discharged. As the cableway on the sea section has a capacity of 100 tons per hour each way this gives a total capacity, when used to its fullest extent, in either direction of 200 tons per hour. The cranes have a capacity of 100 tons of ore loading, and 60 tons of sand and 40 tons of coal unloading, giving a total capacity for both cranes of 200 tons per hour. A ship of 3000 tons which formerly required about 30 days to take in her freight now accomplishes the operation in two or three days, while at the same time the system has dispensed with the extensive fleet of barges and some hundreds of workmen occupied in transporting the ore from the shore to the ship at anchor in the roadstead. As work is often maintained day and night continuously, the whole of the plant is electrically lighted including the supporting standards of the sea section of the cableway.

Mining at Grass Valley and Nevada City

The Veins Dip about 30 Degrees from the Horizontal and the Ore Is Lowered in Cars down the Stopes. Inclined Shafts Are Used

B Y G. E. W O L C O T T *

Grass Valley is an old camp. It was discovered even before the days of the famous Comstock in Nevada, the rush to which at one time almost depopulated this California camp. The Empire mine, the second largest producer today, was first opened up in 1853. Grass Valley is as good a camp today as ever in its history, and will doubtless be a gold producer 100 years from now. The distinctive feature of the deposits which makes a discovery in the district of especial importance is the fact that deposits can usually be depended upon to continue to a great depth. There are, of course, exceptions to this rule, or, at least, apparent exceptions, yet the camp as a whole is remarkable for the continuity of the veins. The Empire vein has been worked to a depth of 3500 ft., and the North Star vein,

cal. The North Star vein has an average dip of only 26 deg. from the horizontal, while 30 deg. may be taken as a close approximation to the general dip. There is, however, no general direction of dip. The North Star vein dips east, the Empire to the west, the Maryland to the south, and the Golden Gate to the north. Many of the veins are at times almost horizontal and have even been known to dip in two opposite directions.

The chief producers in the vicinity of Grass Valley in the order of their production are: The North Star, the Empire, the Pennsylvania Consolidated, the Prescott Hill, the Idaho-Maryland, and the Golden Gate mines. The North Star has two 40-stamp mills in operation, the Empire one of 40 stamps, the Pennsylvania Consolidated one of 20, the Prescott Hill

In the neighborhood of Nevada City the principal producers are: The Champion with a 40-stamp mill; Murchie, 20 stamps; Ousteamah, 10 stamps; and Mountaineer, 10 stamps. Most of these mills are run only intermittently, or at part capacity. As a gold producer, Nevada City is behind its neighbor. The Champion has been a great producer, and has been worked to a depth of 2400 ft. in the vein. It is known that there are bodies of ore below this depth, but with present pumping and hoisting facilities greater depths cannot be attained. The ground is now being partly worked by tributors. The company furnishes everything necessary for mining, and the tributors get one-half the gold obtained from the amalgamation plates. All the concentrates go to the company.

EMPIRE MINE

CENTRAL SHAFT, NORTH STAR COMPANY

which has been worked for nearly half a century, has this year been opened up to a depth of 5400 ft., and appears as strong at this depth as nearer the surface.

THE CAMP AND ITS MINES

Nevada City and Grass Valley may be roughly considered as forming one mining camp. While lying four miles apart they are closely connected by an electric-car line, and from a mining point of view the distinctive features of the one are the same as those of the other. The veins are largely of the same form, the ore of the same general character, and mining and milling conditions are largely the same. The distinctive mining features arise from the fact that nearly all of the veins, as far as worked, have been found lying nearer the horizontal than the verti-

cal. The North Star vein has an average dip of only 26 deg. from the horizontal, while 30 deg. may be taken as a close approximation to the general dip. There is, however, no general direction of dip. The North Star vein dips east, the Empire to the west, the Maryland to the south, and the Golden Gate to the north. Many of the veins are at times almost horizontal and have even been known to dip in two opposite directions. The chief producers in the vicinity of Grass Valley in the order of their production are: The North Star, the Empire, the Pennsylvania Consolidated, the Prescott Hill, the Idaho-Maryland, and the Golden Gate mines. The North Star has two 40-stamp mills in operation, the Empire one of 40 stamps, the Pennsylvania Consolidated one of 20, the Prescott Hill

METHODS OF MINING

On account of the flatness of the veins it has been found necessary to adopt stopping methods differing from those usually employed in Western metal mining where the veins are more nearly vertical. The conditions approximate those found in the Rand, the stopes being too flat for the broken rock to run down the stope by gravity. Owing to this fact a system of mining has been evolved, particularly adapted to meet the conditions, and has been brought to a gratifying state of perfection. Shafts are in nearly all cases sunk on an incline to follow the vein, and hoisting is usually done in skips which automatically dump into receiving bins at the surface. Skips are loaded from bins built at the levels just below the level tracks and discharging by bottom gates into the skips below. The station bins are

*Mining engineer, Reno, Nevada.

usually made in two compartments to accommodate waste and ore.

In earlier days levels were usually run rather close together so as to prevent excessive shoveling of material down the stopes. With present methods levels are usually from 300 to 400 ft. apart, and the rock is taken down the stopes by gravity tramways running up into the stopes. The system followed at the Empire mine is shown in an accompanying illustration.

"GO-DEVIL," FOR LOWERING BY GRAVITY

The main level having been run, a raise is made near the center of the orebody and put through to the next level, or to within from 75 to 100 ft. of it. Auxiliary drifts are also started along the vein at intervals of from 75 to 100 ft. At a point just above the last intermediate drift is placed the mechanism which serves to raise and lower the cars in the stope. This consists essentially of two drums upon which the cables are wound and a brake wheel, the friction being regulated by means of a post brake. One drum is so arranged that it may be revolved in the shaft, or keyed to it as desired. This allows the length of rope to be regulated to suit the auxiliary levels.

A double track is laid down the raise and turn sheets placed at the intersection of the drifts and raises. Stopping is carried on simultaneously at the different drifts, and the ore is loaded into cars and trammed to the turn sheets, where it is lowered by the gravity tram. Short lengths of rails are placed over the turn sheets when lowering from drifts higher up in the stope. The cars on the tramway dump automatically into chutes at the main level.

By another method the driving of intermediate drifts is dispensed with, and stopping is carried on only at one face. The lowering drum may in this case be

placed nearer the lower level. As the stope progresses the drums are carried farther up the stope, or may remain stationary, the cables being carried over pulleys just above the turn sheet. In this case the lowering drums must either be to one side of the track or high enough for the cars to pass under them.

THE NORTH STAR SYSTEM

The method used at the North Star

METHOD OF WORKING

track extending up into the stope; chutes are placed at the bottom and arranged so that the stope cars in descending dump into them automatically. At a convenient distance above the level, depending upon the slope, a turntable is placed and tracks are laid to the chute. Tracks also extend in each direction from the turn sheet, the rails being so placed as to maintain the proper inclination for tramming in the stope. End-dump cars holding 1000 to 1500 lb. are used on these tracks, the ore being shoveled into the cars and the waste stowed below the tramway. The full cars are trammed to the turn sheet and then lowered by means of the go-devil, which is attached to a single stull directly above the turn sheet.

After the stope has advanced 30 or 40 ft. the auxiliary track and turn sheet are taken up and moved up the stope to make another auxiliary level, and stoping proceeds as before.

THE NORTH STAR GO-DEVIL

The go-devil, here spoken of, is the invention of Manager Foote, of the North Star mine. It is a patented article and is manufactured by the Taylor Foundry and Engineering Company, of Grass Valley. An accompanying sketch shows its construction and method of operation. The lowering cable passes around all these pulleys in the direction of the arrows. A central brake block is arranged to apply friction to all three of the wheels on which the rope winds. In lowering a car one man applies the brake by means of

DRUMS FOR LOWERING BY GRAVITY

differs from that employed at the Empire. Raises are not run, except for ventilation, and work proceeds at one breast only. The cars are lowered in the stope by a device called a "go-devil." The accompanying sketches show, without much explanation, the system used. Above the level for from 30 to 50 ft., according to the pitch, the rock is shoveled directly into cars or into chutes from which the level cars are filled. The ore is rough-sorted in the stopes, and the waste is used for filling in behind as the stope advances.

At intervals, as desired, space is left in the filling for the placing of a double

the lever arm which draws it against the wheels at B B B.

This contrivance has certain advantages over the drums previously described. It is less cumbersome, it occupies little space in the stope and requires only one stull for a support. The machine is so light that in changing from one auxiliary level to the next, one man can carry the whole thing. It has the disadvantage that in changing levels the rope must either be spliced or exchanged for a longer rope. If a long rope is used to start with it must be coiled up near the ends attached to the cars and is apt to be in the way.

BREAKING GROUND

Stoping is usually done with 2¼-in. piston machines. The veins are too flat to allow the general use of air-hammer drills without hollow steel.

At the North Star mine shooting is done only once each day, this work being performed by blasts after the regular shifts have quit work. The first shift starts at 7 a.m., and works until 3:30 p.m. The second works from 4 p.m. to 12:30 a.m. After this the blasters come in and shoot the holes. Two shifts are taken to a drift round, a one-man 2¼-in. machine being used. By this method the smoke nuisance is largely overcome, for men do not have to go to work directly after firing, and time is allowed for clearing the atmosphere.

The mines, as a rule, have to contend with considerable quantities of water, especially during the rainy season when much surface water finds its way under ground. Cornish pumps are generally

An Important Amalgamation of Transvaal Mines

SPECIAL CORRESPONDENCE

The terms of a large amalgamation scheme, involving some of the more important and best known mines of the Central Rand, were announced on the eve of Christmas. A new company, to be called the Crown Mines, Ltd., is to be formed on July 1, 1909, to embrace the present Crown Deep, Crown Reef, Langlaagte Deep, and Robinson Central Deep, all producing mines, together with a large area of adjoining and deep-level claims. The new company will have a nominal capital of £1,000,000, divided into 2,000,000 shares of 10s. each, the market quotation for which is now nearly £7 per share. The nominal capital, therefore, will be curiously out of proportion to the real capital, which, according to the present

ground owners and to sundry other interests.

An amalgamation of companies in this section of the Rand has been talked of for some time. The Crown Reef and the South Rand companies own detached claims lying on the dip of the Crown Deep and Langlaagte Deep, and it was obvious that to enable this ground to be worked economically some combination of forces was necessary. But it was not generally known that the amalgamation scheme would include such deep-level ground as that owned by the new Vierfontein mines and the South Deep, Ltd.; ground which, lying wholly outside the broken up area, was on a different footing. The necessity for the inclusion in the scheme of these very deep claims is not so apparent as in the case of the ground above. A compact block with a long life ahead could have been formed without them.

That criticism would be specially directed

METHOD OF LOWERING ORE IN SHOES

employed, usually driven by water power. Aside from the original cost of installation and the amount of room occupied, they have given better satisfaction than the more modern types of pumps.

The bill for the organization of a State Geological Survey in Massachusetts, introduced in the legislature of 1908, was referred to the legislature of 1909. Inasmuch as Prof. T. A. Jaggar, Jr., is about to start on a voyage, which will take him away from Boston for about eight months, the chances are that nothing will be done about the matter this year.

The precipitation of copper from its solutions by means of aluminum or zinc is not recommended in assaying low-grade ores by A. C. Claudet (*Bull. No. 50* I. M. and M.) owing to the great difficulty of precipitating the last traces of copper. In rich ores this does not matter much, but in low-grade ores the obtaining of the last 0.01 per cent. becomes important.

market valuation, is in round figures £14,000,000. It is estimated that the company will own some 2000 intact mining claims together with the freehold of 2587 morgen of land. The present milling plant of the combined properties is equal to 137,700 tons a month, and an additional plant is to be erected, so as to increase the production to 150,000 tons a month. The prospectus of the scheme anticipates that profits to the extent of 130 per cent. or 13s. per share will be distributed annually, equal to 9 per cent. on the present market value.

The Crown Reef, Crown Deep, Langlaagte Deep and Robinson Central Deep will, of course, receive the bulk of the new capital, about 70 per cent. being allotted to the shareholders in these mines. The South Rand, a company owning ground to the south of the Crown Deep, and which is being developed through the shafts of that company, is to take 14 per cent. The Paarl Central and Langlaagte Royal take about 5 per cent., while the balance of 11 per cent. will go to the deep-

to this feature of the scheme seems to have been anticipated as the announcement of the terms of the amalgamation calls attention to the fact that for this very deep ground only 8½ per cent. of the proposed stock issue is to be paid. As a percentage the figure seems small, but has a more important appearance when computed as cash. Inquiry will doubtless be made, if the information is not given officially, as it should be, as to what interest the promoters of the scheme and their friends held in this deep ground, and on what grounds this speculative property is being offered to the shareholders in the producing mines. It ought not to be lost sight of that the proposed scheme will extricate the owners of the deep claims from an embarrassing position. They obtain securities, which will be readily marketable and worth about a million of money, for property which costs a considerable sum in licenses to hold, and which will require a large expenditure and a long wait before any profit can be earned. A strong case must be made out

for the necessity of throwing these claims in with the better known ground above. It is not suggested that the claims are being put in at a figure beyond their value. No doubt the valuation put upon the ground is supported by professional opinion. The point is, are these claims necessary and would their inclusion be advocated if the promoting house or its friends were not interested?

This is not the first case where deep-level ground of speculative value, which carried heavy financial responsibility, has been tacked on to producing claims. It was only a short time ago that the East Rand producing mines were made to absorb a large area of ground of speculative value—ground upon which the development work done had been anything but encouraging. Another amalgamation of the same character is that now proposed for the South Nourse and Nourse mines. Shareholders in dividend paying mines

take in a partner owning claims which, on account of the depth of the reef and the absence of development, are necessarily of uncertain value. Owing, however, to the conditions that prevail on the Rand the shareholders have in practice very little say in the matter. Amalgamation schemes are arranged for them by one or other of the financial groups, who, although occupying the position of trustees of the shareholders in the producing mines, are at the same time sellers, at a price which they themselves decide, of property in which they may be the sole or main proprietors.

The policy of amalgamation, now so much in vogue and in favor of which there is much to be said has created an unhealthy, if not dangerous situation, as it opens the door to an unfair disposal of unmarketable property. Amalgamation schemes, therefore, require the most careful scrutiny from the shareholders

of enhanced profits due to economy gained by working on a larger scale. As pointed out above, the calculation of the profits over the long period is not based on data of the same reliability as in the case of the mine with a short life, and consequently the reconstruction of the investment carries with it the element of speculation. In making this criticism on amalgamations, it must not be understood that the writer wishes to attack the Crown mines' scheme. With the exception of the inclusion of the very deep claims—the necessity for which seems doubtful—the scheme appears to have been fairly prepared. When the reports of the engineers are published—they are due to arrive in February—further criticism may be necessary. But from the information available a good case for amalgamation appears to have been made out and a fair valuation put upon the various interests involved. A scheme of this magnitude must have been difficult to arrange, and the promoters are to be congratulated on their success. It may be assumed that they have obtained the approval of the principal shareholders and there is little reason to doubt that the scheme will be carried out, although, of course, it has still to be formally confirmed by the shareholders of the different companies concerned.

MINERS IN TRUCK READY TO DESCEND, NORTH STAR MINE

may be pardoned for being suspicious that the reasons which the promoters urge so vigorously in behalf of their amalgamations, namely, long life and reduced costs, are not the sole reasons that inspire these proposals. It does not seem harsh criticism to suggest that the amalgamations are not always promoted entirely in the interests of the producing mines, but that they find favor because they release a financial house from a difficult position; and make marketable property which would otherwise be a white elephant. It is difficult to imagine, for example, the Nourse mines shareholders being particularly anxious to purchase the South Nourse property, the development of which has so far been disappointing. Neither would one expect a shareholder in the Robinson Central Deep or Crown Deep to be keen to acquire Vierfontein or South Deeps claims. Such shareholders would probably prefer to keep what they have to themselves rather than to

in the producing mines, especially in cases where deep-level claims, which have no chance of being productive for a long period ahead, are proposed for absorption.

The main arguments used in favor of amalgamations are those of long life and reduced costs—all sound arguments, but arguments that can be overdone. The great plan in the argument of long life is the assumption that values will continue much as they have done in the past. There are few mines with ore reserves developed more than three years ahead of the mill. Beyond that the values are to some extent problematical, yet the continuance of payable ore is assumed with composure, and estimates of production made for 20 or 30 years ahead.

The principle underlying all these amalgamations is that the shareholders in the mines with short lives and with profits that can be closely estimated, will receive an equivalent dividend or annuity spread over a longer period with the advantage

Refunds of Payments for Surveys

SPECIAL CORRESPONDENCE

On Jan. 28 the House of Representatives passed with some minor amendments the Englebright bill for the relief of applicants for mineral surveys. The bill reads as follows:

"Be it enacted, etc., That the Secretary of the Treasury be, and is hereby, authorized and directed to pay, out of the moneys covered into the Treasury from deposits made by individuals to cover cost of work performed and to be performed in the offices of the United States surveyors-general in connection with the survey of mineral lands, any excess in the amount deposited over and above the actual cost of the work performed, including all expenses incident thereto for which the deposits were severally made. Such repayments shall be made to the person or persons who made the several deposits, or to his or their legal representatives, after the completion or abandonment of the work for which the deposits were made, and upon an account certified by the surveyor-general of the district in which the mineral land surveyed, or sought to be surveyed, is situated and approved by the Commissioner of the General Land Office."

It is estimated by the Land Office that the total amount payable under this measure will be about \$60,000. This sum will

go in small amounts to a considerable number of persons who have heretofore been unable to collect owing to lack of power in the administrative authorities to make payment.

The Gold Deposits of French Guinea

For some years the goldfields of French West Africa have attracted considerable attention in France; this was especially so in 1908. The administrative division of French Guinea consists of the following colonies: Ivory Coast, Dahomey, Guinea, Sénégal, Upper Sénégal and Niger, and Mauritania; viz., the colonies of the west coast, Congo alone excepted.

The deposits of Upper Guinea, which are practically all located in the district of Siguiri, have been examined by many mining companies. This mining camp may be easily reached from Bordeaux, via Dakar. From Dakar the traveler goes by

high angle. The strike of the rocks which is about northeast-southwest is quite uniform throughout the goldfields. The deposits are closely related to the eruptive rocks, such as granulites and diabases, which have the same direction as the schists and slates and which can be followed for more than 1000 km. Probably the eruptive rocks are the source of this gold and the deposits were formed by circulating waters that collected the gold. In fact the closer the deposit is to the eruptions, the richer it is.

All the rocks, especially the crystalline rocks and slates, down to permanent water level are decomposed into an earthy and brittle material called laterite. These shales are protected against complete destruction by a ferruginous conglomerate which covers immense areas characterized by extremely poor vegetation.

The country is very flat but presents some depressions which owing to the concentration of gold in them are of special interest from the mining view-point.

The accompanying ideal cross-section, as

Among the many others who sent prospectors to Guinea, two companies—the Compagnie Minière de Guinée and the Compagnie des Mines de Siguiri—have begun to work their properties and are installing machinery to ascertain the best way of treating this auriferous clay. They have done considerable work in drilling or sinking small pits to test their property, in preparing roads for transporting the heavy machinery and in getting wood for burning under the boilers. They have also had to provide the necessary supply of water for washing the auriferous laterite.

In Kobako valley the Compagnie Minière de Guinée will dig the laterite with two excavators of the ladder type each having an estimated capacity of 500 cu. m. per day or 10 hours. One excavator will dig out the ferruginous conglomerate while the other will work on the laterite proper. Ore will be delivered to a movable washing plant consisting of a big revolving screen of special design for completely disintegrating the material, a 10-in. centrifugal pump delivering water inside the screen, a 12-in. centrifugal slime pump, a 100-h.p. vertical engine and a water-tube boiler of the portable type. This plant is placed on a platform mounted on eight wheels, and will follow the excavators as the work progresses. The oversize from the screen, which consists mainly of gold quartz, is loaded into cars and trammed to the milling plant, equipped with a Dodge crusher, a Huntington mill, 3 ft. 6 in. diameter, and silvered copper plates. The undersize is elevated by the 12-in. pump to a sluice box. At the head of the sluice, for experimental purposes, are placed two gold-saving tables of the Turner type fitted with coconut matting and expanded metal.

The Compagnie des Mines de Siguiri is to work its Fatoya hill property. Small canals fed by a centrifugal pump will transport the ore to a system of sluices with undercurrents. The quartz separated by means of grizzlies will be crushed and amalgamated in two milling plants, both similar to the one erected by the Compagnie Minière de Guinée. These plants are expected to be ready to run early in 1909.

The H. W. Johns-Manville Company, of New York, is introducing a chemical compound, called Leak-No, which resembles powdered iron, and when mixed with water and applied like putty to cracks, or other defects, in iron or steel articles, metallizes and becomes a permanent part of the article to which it is applied. When hard it much resembles iron in color. The manufacturers offer to refund the purchase price in case it fails to stop any ordinary leak in anything made of iron or steel against any pressure of oil, steam, gas, air, ammonia or water; and to stand any heat or chemicals that iron will stand, when applied according to directions.

IDEAL CROSS-SECTION OF AURIFEROUS DEPRESSION IN FRENCH GUINEA

A is barren clay; B, ferruginous conglomerate; C, auriferous laterite; D, barren laterite.

rail to St. Louis in Sénégal (264 km.); thence by steamboat up the Sénégal river to Kayes (900 km.), a journey of 5 to 6 days; again by rail to Bamako (496 km.) and then by boat on the Niger river to Siguiri (300 km.). The total distance between Bordeaux and Siguiri, which is 6200 km.—4300 on sea, 760 on rail and 1200 on river—may be covered in 20 to 25 days at the time of high water; August, September and October.

The gold deposits of that part of the world were lately described in a lecture given in the hall of the Société de Géographie, of Paris by Commandant Villiaume, who examined much of this area during the years 1905 to 1908. According to him, the gold deposits of eastern Guinea have, generally speaking, many features in common with the gold veins of Rhodesia and some other African goldfields, the conglomerates of the Rand, of course, being excepted.

Most of the region is underlaid by old clayey sediments changed by an intense general metamorphism into banded crystalline schists and slates that dip at a

presented by Commandant Villiaume, gives a fair idea of these auriferous depressions. Stratum A consists of barren clay; excellent bricks are made from this and used for building houses for the European staff. B is the ferruginous conglomerate which is always water-laden. The section shows how it connects with the part exposed at surface by erosion. The conglomerate varies in thickness from 1 to 10 m. It is very hard at surface where it has been dried by the tropical sun, but below surface it is much softer. It was lately found to be auriferous in the depressions or close to them. The soft portion proved to be the richest part, containing in places as much as 12 grams per cubic meter (about \$6 per cubic yard). C is the auriferous laterite, saturated with water. Its thickness varies from 1 to 16 m. The gold is distributed fairly regularly through it. D is barren laterite.

The width of these depressions generally varies from 30 to 150 m. The main valleys or depressions are 25 to 60 km. long, while the secondary ones are only 2 to 10 km. long.

The East Tennessee Zinc Mining District

The Dolomite in Which the Mineral Is Found Is Abundant and Easily Worked, but It Is Too Low-grade for Small Operations

BY SAMUEL W. OSGOOD*

The zinc district of east Tennessee was mapped in the years 1896 to 1901 and is described in folios issued by the U. S. Geological Survey at the time. The maps gave the district in general three nearly parallel zinc belts extending through Tennessee for 40 to 50 miles and about 20 miles apart. These belts

rise to cross-fissure zones of fracture. In these zones are the richest orebodies. The ores are sulphides and they occur in the filling of the fracture zone or breccia continuous with calcite and dolomite and not in the rock. No barytes is present in these ores in the rocks. Where the clay and sand of the surface is 20 to 30 ft.

The Straight Creek mine and "Lead Mine Bend" mine are two properties on the northern belt, only one of which, the Straight Creek mine, is now operating. It is with the central belt that this article is principally concerned, for on this belt are the most extensive operations owing to accessibility to the railway, and

BLÉNDE QUARRY, VALLEY ZINC MINE

JOLLY FARM MINE

CONCENTRATING MILL, HOLSTON ZINC COMPANY

HOLSTON ZINC COMPANY GRAVITY TRAMWAY

are each only a few hundred feet wide and extend in a northeast-southwest direction, following the general strike of the Appalachian system of folds and faults.

The ores are contained in the Knox dolomite, a soft, easily broken rock, lying between Silurian and Cambrian strata. In places local disturbances have given

thick, carbonates and silicates are found to overlie the sulphide ores.

The central belt occupies the valley of the Holston river, and is called the Holston Valley zinc belt. This belt has ores containing zinc with no lead and less than 0.5 per cent. iron. The more northerly orebodies near the Powell river and the southerly belt near the French Broad river carry both iron and lead.

to the simple nature of the ores which are more easily treated.

The Holston Valley zinc belt is about 40 miles long in a northeast-southwest direction and from 50 to 700 ft. wide. Knoxville is about in the center of the belt. The Southern Railway's double-track line between Washington and Chattanooga traverses almost the entire length of the belt, hauling large amounts

*Consulting mining engineer, Chicago, Ill.

of Tennessee coal from near Knoxville to the coast.

CHARACTER OF ORE

Carbonate ores have been shipped from the district for many years. They occur in a bed of red and yellow clay overlying the dolomite containing the yellowish blende. The shipments of carbonates have been spasmodic and the future of the district will no doubt depend largely on the success of treating the sulphide ores.

The east Tennessee zinc ores, while remarkable for their chemical purity and freedom from the undesirable iron and lead minerals usually found in zinc ores, have never until recently been of much commercial importance owing to the low

operations that the entire brecciated mass can be mined and milled on a large scale in a modern concentrating mill, maintaining a fair grade of product.

METHODS OF WORKING.

The first mining and milling of the zinc blende ores on any considerable scale was undertaken by the Edes, Mixter & Heald Zinc Company, in 1883 at Mossy creek. This first mill was erected to wash the dumps of blende cobbled from the carbonate ores, and was so successful that in 1885 an 80-ton mill, including crusher, rolls and jigs was erected. This mill treated hand-sorted ore from a large quarry for several years. It was closed

high per ton of ore mined, the cause being simply the inconvenient methods for handling too small a daily tonnage.

The third of these small mills was built by the Roseberry Zinc Company, about $1\frac{1}{2}$ miles west of Mascot in 1900. This mill was an advance on former plants, but the ore was still hand-sorted in the quarry, one car of waste being secured for each car of ore. It was one of the inefficient, old-style Joplin mills of small capacity; but it shipped many carloads of high-grade zinc concentrates. The capacity was low, the mill inefficient and poorly built for continuous operation; consequently the costs per ton were again too high for commercially economic results. The ore was mined in a quarry at

MAP OF KNOXVILLE ZINC BELT

grade of the ore and the methods of milling. Actual results show that the cause for the lack of success was the small daily capacity of the plants, the hand-sorting of the ores bringing the cost per ton of ore treated to an abnormally high figure. The crude method of building the mills also made steady, daily operation over long periods impossible because of frequent and costly repairs.

The blende, while in large bodies of a brecciated rock, occurs in bunches or small seams as a filling in the breccia, of the fissure zone. The ore has in the past always been hand-sorted to give a mill feed assaying from 8 to 12 per cent. zinc. Recently, however, it is thought to have been demonstrated by large commercial

in the panic of 1893, but was re-opened by the John Weir Lead and Zinc Company in 1900 and operated for a few months. The small daily capacity and the crude equipment brought the costs per ton so high that the mill was closed after a few months.

The second of these small, unsuitable mills was erected by the Ingalls Zinc Company, about $1\frac{1}{2}$ miles southeast of New Market in 1898. The ore was quarried from near the surface. Here again the ore was hand-sorted, the capacity of the mill being small like that on Mossy creek. The ore was hand-sorted to about a 12-per cent. zinc before milling, and a high-grade concentrate was shipped, but the operating costs were very

first and later a shaft nearly 300 ft. deep was sunk and mining in stopes was begun.

The fourth of the small mills was built by the Holston Zinc Company about $\frac{3}{4}$ mile west of Mascot in 1903, and this was another advance, especially in the development of a more elaborate jigging system. This mill was, however, of small capacity, and the ore was still hand-sorted in the quarry. In 1905 the shaft was sunk to 180 ft. and underground stope mining was started and milling done with no hand-sorting, which showed another advance. At this time a few slime tables were also added to the mill equipment. The daily capacity of the mill was small, the operation not in experienced hands and the costs per ton relatively high.

The Holston Zinc Company's mill was partially re-equipped in 1907 along lines suggested by A. M. Hewlett, the president of the company, and operated under my management. Mr. Hewlett's untimely death in 1907 had much to do with the Holston Zinc Company's failure to complete the re-equipment of this mill. However, the plant was operated in its incomplete state for several months, and shipments of concentrates were made on a scale not possible before that time in the east Tennessee zinc districts. This showed at once the correctness of Mr. Hewlett's judgment in demonstrating on a commercial scale that all it required to make a success of the Tennessee zinc ores was large capacity to reduce the "per ton" cost, a mill elaborate enough to save the zinc in the ore and of a sufficiently stable construction for continuous daily operation.

The last year's operations on the Holston zinc belt include, besides those of the Holston Zinc Company, the shipments of carbonate ores and prospecting of its blende ore deposits by the New Market Zinc Company and prospecting on the Ingalls or Jolly Farm mine southeast of New Market.

OPERATIONS IN THE DISTRICT.

At the Holston property the ore is mined at a depth of 160 ft. in large stopes 50 or 75 ft. wide and carried to a height of 40 ft. Another level has been started above, and drifts have been started to allow of stoping at a considerable distance from the shaft. This will allow the use of a caving system making it unnecessary to strip the 70 ft. of clay and soil on the surface to get at the ore where it comes to the top of the rock below the soil. Mining is done by machine drills.

In this mine all rock is taken from the stopes for the entire width, no hand-sorting being done. All ore is dumped into the crushing plant and sent from there to the mill. The mill has three departments, a rougher department from which a large amount of the waste rock formerly picked out by hand is sent to the tailings dump, and both a coarse and fine finishing department.

The New Market Zinc Company operates on a large tract of land southeast of New Market on Lost creek where it has developed what appears to be one of the largest bodies of zinc-carbonate ores in the district. The company started operations about two years ago and after extensive development work began shipments last fall.

The Roseberry Zinc Company started operations in 1900. Ore was quarried, hand-picked or sorted and sent to the crude Joplin mill. In 1904 the company made the first successful attempt to develop the Tennessee orebodies by drilling as had been done in Joplin. The drill

disclosed a large orebody which was opened by sinking a shaft 200 ft. deep. The ore was mined in large stopes with machine drills. The ore was only roughly sorted as fed to the mill.

During the last year on the Ingalls or Jolly Farm property a new orebody has been prospected about one-half mile north-east of the old works.

A quarry or open pit has been made 165 ft. long and 40 to 50 ft. wide. The orebody was found at the surface, and over the area it has been opened 10 to 15 ft. deep. The orebody has a slight dip, being nearly horizontal, and is said to be 600 ft. wide. The ore is in a brecciated zone and several seams of blende of a foot to several feet in width will average high in zinc, although no doubt the entire orebody will average much lower, probably about the same as the rest of these ores when mined on a large scale.

The old works of this property consist of an open pit or quarry where the blende was mined for treatment in a small concentrator. The ore was mined and sorted in the quarry and hauled up an inclined track by a small hoisting engine. It was dumped upon a platform to be again hand-picked and then fed to the crusher. There were two quarries, 80 ft. wide by 100 ft. long and about 50 ft. deep. An old mill run shows that 500 tons of hand-sorted ore yielded 52 tons of concentrates assaying 53 per cent. zinc, which is very fair considering the crude equipment of the mill.

The Valley mine is the best looking of the partially opened but inoperative mines of the belt. This mine is at Friends on the Southern Railway, 14 miles from Knoxville. The orebody is opened by an open quarry, about 50 ft. long, 15 ft. wide and 10 ft. deep. The quarry is near Lost creek and the blende appears at the surface of the ground where the creek has washed away the soil. The ore occurs in a brecciated fissure zone and is in appearance identical with the Mascot and New Market ores. Carbonate ores have been shipped from the clays of the sub-soil on adjoining properties, which seems to indicate a large orebody on this property.

THE LOVES CREEK MINE

The Loves Creek mine at Loves creek five miles from Knoxville was partially explored several years ago and good ore was found. A 50-ft. drill hole showed ore all the way to the bottom. There is a good mill site with ample water for milling and good surface indications. This is at present among the inoperative properties, but the owners expect to develop it into a mine.

IMPROVED METHODS NECESSARY

Throughout the entire length of the zinc

range from Knoxville to Jefferson City, wherever a creek has washed its way through the soil in crossing the ore zone good blende may be seen in the bed of the creek. The commercial possibilities of the district have been proved by the many carloads of high-grade blende concentrates carrying from 50 to 56 per cent. zinc and the carloads of high-grade carbonate ores which have been shipped. That the milling of these ores has been successfully accomplished has been shown in the case of the Holston mill; it remains but to provide sufficient capacity in the mill as designed to eliminate overcrowding of the individual machines. Overcrowding causes loss because the ore as it flows automatically through the mill by gravity after being ground and mixed with water must remain on each machine long enough for that machine to get the concentrates out of it. If the machine is crowded the ore stream flows across too quickly for this to be accomplished and losses occur which reduce the total efficiency of the mill as well as the grade of the concentrates.

From 100 tons of ore assaying 3.7 per cent. zinc, 3.7 tons of concentrates assaying 52 per cent. zinc were produced, representing a 52-per cent. mill efficiency. The efficiency of the coarse departments was 65 per cent. and with added capacity in the fine department it should be easily possible to increase the efficiency to above 65 per cent. which is a high efficiency for a zinc-concentrating mill on these ores. The efficiency on all sizes up to 60 mesh was above 65 per cent., and frequently as high as 81 per cent., but on the sizes below 60 mesh the losses were great.

THE REMODELED HOLSTON MILL.

During seven months after the mill was overhauled in 1905, 239.5 tons of concentrates were shipped assaying from 49 to 59 per cent., and averaging 56 per cent. zinc. Since Holston zinc ores contain no lead or iron they are very desirable for use in making high grades of spelter.

While the grade of concentrates produced during the seven months' run of the mill was highly gratifying, the daily capacity was not satisfactory. The tonnage treated during this period averaged 38 tons per day, at the rate of 6 tons per hour for 6½ hours per day. The faulty construction of the mill required frequent stoppages, giving an average of only 6 1-3 hours operation per day out of a possible 12 hours. The efficiency of the mill was low because of the lack of the proper facilities for treating the large proportion of fines made in the rolls. There were four Card tables, but owing to the lack of other accessory apparatus and the lack of experience in the use of them, a low percentage of savings was made on the fine sizes. A large proportion of the

concentrates consisted of very coarse sizes.

The machines required for each 100-ton capacity were from a study of this mill found to be as follows: one bull jig, six finishing jigs, three coarse concentrating tables of Wilfley type, and one slime table. This is allowing 10 tons per day per jig capacity for the coarse sizes, 10 tons for the moderate sizes and 8 to 10 tons for the finer jig sizes; also allowing 12 tons per day capacity for two Wilfley tables and one table extra to retreat the middlings; also allowing one slime table of a capacity of 10 tons.

In short, a detailed study of the practical operation of milling Tennessee zinc ores based on the actual performance of this mill when treating ore at the rate of 175 tons per day shows that it can be made commercially successful. On the same basis of machine capacity, jigs are to be added to bring the total capacity of the mill up to 300 tons per day. Such a mill will make at least 11.1 tons per day of concentrates from a 3.7-per cent. ore, and of a grade at least 56 per cent. and more probably 58 to 60 per cent. Based on the actual cost of operating a 125-ton plant, it is estimated that the operating costs will be \$312 per day for a 300-ton mill and mine.

Motor Driven Centrifugal Pump for Mine Use

By CYRUS ROBINSON*

Many mine superintendents have a strong prejudice against centrifugal pumps for underground work. The troubles that have arisen with centrifugal pumps have been very frequently the selection of low-volume, high-head turbine pumps, and of motors not specially designed to work under the varying voltage usual at mines. A turbine pump is quite sensitive to changes of speed, and unless properly designed, a great deal of trouble is experienced in losing the water column whenever there is a sudden drop in speed due to a change in voltage. On account of this prevailing prejudice against centrifugal pumps for mine use I am giving in this article the results of some tests made upon a Sulzer pump at the Ojuela mine of the Compañía Minera de Penoles at Mapimi, Mexico.

In placing the order for this centrifugal pump in July, 1907, I made provision for the conditions to be met with for I specially emphasized the varying voltage, the height of lift, volume of water to be delivered and the efficiency to be guaranteed under these conditions in the following specifications: The pump shall be a six-stage Sulzer pump directly connected to

the motor. The permissible variation in speed shall be between 1750 and 1770 r.p.m. on account of fluctuating voltage which may vary between 400 and 460 volts. The total lift including suction, pressure and pipe losses, against which the pump must work, is 1020 ft. The amount of water to be raised shall be from 600 to 760 gal. per minute, according to the speed. The motor shall have an output of from 223 to 290 h.p., according to the amount of water delivered. The pump shall be built for direct connection to the

meine Electricitäts Gesellschaft, and directly connected to the pump. It shall be so designed that the speed shall not fluctuate more than from 1750 to 1770 r.p.m. when the voltage varies between 400 and 460 volts. It shall use a three-phase, 60-cycle current and shall deliver 300 h.p. under the voltage stated. This motor shall be delivered complete with foundation plates and bolts, slide rails and ratchets to facilitate mounting and dismounting, as well as elastic coupling for connecting it with the pump. A rheostat

TEST NO. 6 OF SULZER PUMP, OJUELA MINE, MAPIMI, MEXICO

motor, and shall be made of special cast iron, while the impeller and the guide wheels shall be of bronze, and the shaft of special nickel steel. This pump shall be delivered complete with foundation plate and bolts, pressure gage, priming funnel, elastic coupling, air and drain cocks, complete set of wrenches, one water gage, 7 in. in diameter equipped with a bypass, one check valve 7 in. in diameter, and one strainer with foot valve 7 in. in diameter.

The motor shall be of the slip-ring induction type, manufactured by the Allge-

shall also be furnished, as well as a switchboard panel (a marble slab with iron frame), on which shall be mounted a bracket with a lamp and shade, one ammeter, and one three-pole switch, with fuse holders and three fuses. The pump shall be guaranteed to work at an efficiency of 70.5 per cent. when the total lift is 1020 ft. and the pump is delivering 600 gal. per minute; and an efficiency of 68.5 per cent. when delivering 760 gal. per minute, against a lift of 1020 ft.; or in other words, with a voltage fluctuating between 400 and 460 volts, and delivering

*Consulting engineer, 82 Beaver street, New York City.

volumes of water between these limits, the pump shall work with an average efficiency between 69.5 and 70 per cent.

THE PUMP TESTS

After this pump had been in operation for some time, C. C. Hoke, mechanical engineer at Mapimi, made several tests on it. The water was measured by noting the fall in tanks having a regular cross section and whose capacity was 508.7 gal. per inch of depth; the suction of the pump was connected to these sumps. The delivery head was calculated from the pump pressure gage, and to insure accuracy the gage was calibrated between tests

The Anthracite Miners' Demands

The demands of the anthracite miners, as formulated at their district convention, and now amended and approved by the general convention of the United Mine Workers at Indianapolis, are as follows:

"First—That an agreement shall be negotiated between the representatives of the miners and the operators of the anthracite region, and all disputes arising under the contracts shall be adjusted as provided for in the said agreement.

"Second—We demand the complete recognition of the United Mine Workers

ployees paid more than \$1.50 and less than \$2 per day shall receive a 5 per cent. advance.

"Sixth—That the system whereby a contract miner has more than one job, or employs more than two laborers, be abolished.

"Seventh—That the employers be required to issue uniform pay statements, designating the name of the company, the name of the employee, the colliery where employed, the amount of wages, and the class of work performed.

"Eighth—That the contract shall be made for a period of one year."

The convention authorized the levying of such assessments as may become necessary

No. 5 and No. 6 and further checked against the actual head plus calculated friction of delivery. The results of these tests are given in an accompanying table, and a curve of test No. 6 is given as that test is representative of the general conditions. In another curve the variation of pump delivery at different speeds is shown. The accompanying illustration shows the pump that was tested, but as finally installed a more flexible coupling than the one shown was used so as to give a certain elasticity between the motor and the pump.

The temperatures of the motor and bearings were as follows: Stator laminations, 60.2 deg. C.; stator windings, 61.4 deg.; rotor winding, 54.5 deg.; bearings (oil temperatures), 65.5 deg.; temperatures of air, 29.1 deg. Centigrade.

The efficiency obtained compares favorably with the best type of triplex, geared pumps, including motor, and if the volume of water handled were increased with the same head, using, of course, a larger pump, the efficiency would be still better, but conversely if the volume of water is smaller, the efficiency would decrease. As illustrating this point, tests on a similar pump delivering 200 gal. per minute against a head of 600 ft. showed an efficiency of less than 45 per cent. Consequently, in deciding upon the type of pump to install it is evident that careful consideration must be given to the volume and the head. Failure to do this and to include in the specifications a provision that the pump must be designed to work under a varying voltage has been a source of a great deal of the difficulty met with in using centrifugal pumps for mine work.

TESTS OF SULZER PUMP, OJUELA MINE, MAPIMI, MEXICO

of America as a party to negotiate a wage contract, and that the United Mine Workers of America shall be recognized in our right to provide any method we may adopt for the collection of revenues for the organization.

"Third—That we demand an eight-hour day with no reduction in wages.

"Fourth—That all coal shall be mined and paid for by the ton of 2000 pounds.

"Fifth—That we demand a definite and more uniform scale of wages and prices for all classes of labor at all collieries in the anthracite region; and that all employees paid \$1.50 or less per day shall receive a 10 per cent. advance, and all em-

sary to assist the anthracite miners, in case a strike should follow rejection of these demands.

It is understood that they will be presented to the anthracite companies shortly by a delegation headed, or accompanied, by President Lewis of the United Mine Workers. This will bring up at once the question of a full recognition of the union. It is not at all probable that these demands will be accepted by the companies, and a prolonged discussion will certainly follow. Whether terms can be made by April 1, when the present agreement will expire, is not by any means certain.

Disposal of Phosphate Lands

SPECIAL CORRESPONDENCE

How to dispose of the phosphate land question is proving exceptionally troublesome to Congress. Two distinct plans for settling the issue have been proposed. One is that of retaining the lands in Government ownership, leasing the phosphate mining rights to individuals, while the other is that of restoring them to private ownership subject to distinct provisions as to the law under which they may be patented. At a hearing before the House Committee on Public Lands, the latter idea has been urged by Judge S. E. Payson in behalf of owners of 36 or 37 locations under the lode land law upon the phosphate territory in Utah and Wyoming. When the rock was discovered, geologists were sent out by capitalists to determine its condition and extent, and at the outset a serious question presented itself to the legal advisers of locators. This related to the form of the location, whether it should be under the lode law or under the placer law since all mineral lands come within the scope of one or the other classification. Attorneys for some of the locators advocated a resort to the lode location system while those representing other locators came to the conclusion that the placer location was the proper form and thereupon proceeded to locate, some as placer and some as lodes. The first case which came before the Interior Department for decision was one known as the Waterloo placer and it was decided that a placer location was the proper form. The Waterloo claim, therefore, went to patent as a placer claim for some of the phosphate land. Later a formal opinion was rendered by the land office that a lode location was the proper method. Then a number of claims went to patent. Everything has been suspended by reason of the action of the President under his order withdrawing these lands last December. Local land offices are refusing to issue patents for land until further orders from the Department of the Interior. The argument of the original locators is that existing law ought to be continued with reference to all these deposits and that the patenting of each deposit should depend upon the character of it as that is made to appear where an application for patent is made. It is their contention that nobody is harmed by a continuation of existing law. As to the locations heretofore made, they have recommended a curative statute designed to protect the original discoverer no matter what the form of his location may be.

It is argued that there is no difficulty in determining whether a given prospect must be treated as a placer or as a lode location. When a lead of underlying rock is found which carries a mineral worth

mining and reducing and under that a rock of the country the location must be taken as a lode. In mining the phosphate rock, the process is not carried on for the rock itself but for the mineral which is contained in it. Hence, it is argued, under the old statute passed 40 years ago, which provided that wherever any rock in place carries with it a mineral of value it must be taken under the lode location while a distinction must be drawn between phosphate rock and marble and limestone or any kind of building stone. The latter may be taken as placer because there is no mineral included.

The real question for discussion is recognized as being whether a change is now advisable, taking into account the facts that the law of extralateral rights has been in force for over 40 years and also for many years previous as a part of the miners' rules and customs, that all metal mining except iron in the western States is carried on under it, and that no extralateral rights acquired during that period could be abrogated by any changes but must continue to exist according to the law at the time of their initiation.

Senator Flint, of California has introduced a bill (Senate 8804) for the same purpose as that suggested some days ago by Senator Smoot but containing a number of new provisions. The bill directs that the Secretary of the Interior shall, after examination and classification of any public lands heretofore withdrawn because of deposits of phosphates supposed to exist thereon, restore to entry, selection, and location any such lands as may be found not to be valuable for the deposits of phosphate. In cases where the lands are actually valuable for their phosphate deposits the Secretary of the Interior is directed to clear the title of all invalid mineral entries, claims, and locations. He is then to issue to citizens of the United States or those who have declared their intention to become such, leases or licenses to work the phosphate deposits belonging to the United States, on such terms and conditions as he may deem proper, or as may from time to time be directed by Congress, provided that the leases or licenses shall be on such terms as will insure the proper development of the deposits, prevent monopoly, and secure disposition of the output at reasonable prices, and that none of such leased deposits, or of their products either in their original or manufactured form, shall be exported from the United States. Any violation of this provision by the lessees or licensees, their assignees or grantees, shall work an immediate revocation and forfeiture of the leases or licenses, and the person or persons so violating the proviso may, upon conviction be fined not over \$1000 for each offense.

In all patents for lands henceforward to be issued there is required to be a reservation of all deposits of phosphates, to-

gether with the right on the part of the Government to enter upon or mine under the land in accord with such rules and regulations as will insure surface owners from loss or damage, or will reasonably compensate them. An important provision relating to the application of the placer and mineral lode law is set forth in section 6 which requires that "where lands containing deposits of phosphates have heretofore been located under the placer laws, or laws providing for the entry of mineral lode claims, said locations may be perfected under the provisions of said laws, but no title acquired to lands containing such deposits under the mineral lode laws shall give the locator or entryman any right beyond the perpendicular limits of his claim: Provided, that in case of any conflict between locators under the placer laws and the mineral lode laws no locations heretofore made of lands containing valuable deposits of phosphate or phosphate rock the respective claims of the locators shall be determined as though location of said lands under either of the was valid when made.

Coal Land Locations

SPECIAL CORRESPONDENCE

The House Committee on Mines and Mining on Jan. 29 reported favorably the Mondell bill relating to the patenting of coal lands. The bill as now before the House reads as follows, amendments being in italics:

"That any person who has in good faith heretofore located, selected or entered under the nonmineral-land laws of the United States, any lands which subsequently are classified, claimed or reported as being valuable for coal, may, if he shall so elect, and upon making satisfactory proof of compliance with the laws under which such lands are claimed, receive a patent therefor, which shall contain a reservation to the United States of all coal in said lands, and the right to prospect for, mine and remove the same. *(The coal deposits in such lands shall be subject to disposal by the United States in accordance with the provisions of the coal-land laws in force at the time of such disposal.)* But no person shall enter upon said lands to prospect for, or mine and remove coal therefrom without previous consent of the owner under such patent, except upon such conditions as to security for, and payment of, all damages to such owner caused thereby as may be determined by a court of competent jurisdiction. Provided, that the owner under such patent shall have the right to mine coal for use for domestic purposes on the land, prior to the disposal by the United States of the coal deposit. Provided further, that nothing herein contained shall

be held to affect or abridge the right of any locator, selector or entryman to a hearing for the purpose of determining the character of the land located or entered by him, and to a patent without reservation if the land shall be determined not to be chiefly valuable for coal, or to abridge or deny the right of any entryman who has earned a title to the land covered by his entry to a patent without reservation."

HOMESTEAD PATENTS ON COAL LANDS

Representative Marshall has introduced a bill to provide for the issue of homestead patents in certain instances. The main provision is that wherever an entry has been made in good faith on lands subject to homestead entry in the State of North Dakota which were afterward classified as containing coal, such entry shall be deemed valid, and upon proof of full compliance with the homestead laws as to residence and improvements a full patent shall be issued to such entryman.

The Copper Mines of Katanga

At the annual meeting of Tanganyika Concessions, Ltd., in December last, Robert Williams, the managing director, made the following statements to the stockholders:

I have the assurance of George Pauling, the well-known railway contractor, whose surveyor has been over the entire route, that he will have the rails through to the Star of the Congo mine in 18 months from the date of signing the contract for construction; and Mr. Gibb, my mining engineer, has also guaranteed to have plant ready at the Star mine in 18 months to produce from 1000 to 3000 tons of copper per month; and I am personally confident that within three years from date the Katanga mines will be producing 5000 tons of copper per month from the eastern section of the copper belt owned by the Union Minière Company, in which we own 45 per cent. of the shares. The cost of the copper from the Star in Katanga will not exceed £15 per ton on the spot, although we believe a considerably lower figure will be nearer the mark, when the Kambove and other mines are producing, but even at £15 per ton the cost would not exceed £25 per ton delivered in Europe via Beira.

THE KANSANSHI MINE

The Kansanshi mine has been producing from 80 to 90 tons of copper per month at a cost of £15 per ton, at the works, and we are sending up a larger furnace, which will produce from 200 to 250 tons per month at a cost of about £12 10s. per ton. We have about £30,000 worth of bar copper in stock at Kansanshi and have entered into a con-

tract to bring the copper to rail-head, and the first shipment of 40 tons has arrived there by this time. Within a year I expect we shall have the railway so close to Kansanshi that we will bring down the whole of the present stock by traction engines to the rail-head, as well as the regular monthly output, and land it in England at £30 per ton. Certainly we should have landed in England within two years from this date 3000 tons of copper from Kansanshi at a cost of £30 per ton. These conditions will steadily improve; costs will go down as the railway goes north.

RAILWAY AGREEMENTS

Last July, I carried through the railway agreements, which I will now explain: A.—The Benguela railway will continue the construction of its line from Lobito bay to the frontier separating Angola from the Congo state between the 11 deg. and 12 deg. parallels south. B.—The Lower Congo railway will construct the section from Ruwe mine to meet the Benguela railway as soon as the lines of approach enable it to do so. C.—The Katanga Railway Company will construct a line from the frontier of Rhodesia to the Star of Congo mine as soon as the Southern railway reaches that frontier. The Katanga Railway Company will extend its line from the Star of Congo mine to Ruwe, and eventually to a navigable point on the Lualaba, as and when circumstances justify that extension. These agreements provided for a "pooling" of gross earnings between the Benguela railway, the Lower Congo railway and the Katanga Railway Company, revisible every 10 years. D.—The Chartered Company agrees to form a company with sufficient funds to construct a line from the present terminus of its railway at Broken Hill to the Congo state frontier. The Chartered Company gives rates for all mineral and other traffic to and from Beira and the frontier of the Congo state and also for all the material for the construction of the Katanga railway from the Rhodesian frontier to Ruwe, and the construction of the railway connecting Ruwe with the Benguela railway on the Portuguese frontier. It is also provided that the agreement between the Chartered Company and the Belgian companies shall continue in force until 10 years after the line to the Star of Congo is completed and open for traffic. This agreement may, however, be terminated when the Benguela railway and the extension thereof to Ruwe shall have been completed, or when more economic rates can be offered by the two northern railways and water routes of the Congo state. These agreements were signed on July 14 last.

ADVANTAGES OF THE BENGUELLA ROUTE

It is evident that when our own Ben-

guella railway is completed it will take the traffic which it ought to get by reason of its being 500 miles shorter to the sea than any other line; in fact it would take most of the traffic even if the length to the sea were the same as other routes. Only by having our own route can we ever control our copper costs. The Chartered Company advised me on Sept. 8 that it was unable to finance its section, and I wrote Dr. Jameson, with whom I had conducted all the negotiations, that I would endeavor to raise the money myself for this section, provided the Chartered Company gave this company the concession to build and own this section, reduce its interest on Kansanshi, and grant me large mineral concession for coal and other minerals, and also provided that Pauling & Co. guaranteed £250,000 of the money required, on condition I got that firm the contract to construct the whole job to the Star at a fixed rate per mile. In reply to this letter Dr. Jameson wrote me that Lord Winchester and Mr. Birch-enough were appointed a committee to deal with my suggestions. We soon came to terms, and an agreement was signed between this company and the Chartered Company on Nov. 4, giving this company full power to form a company before Jan. 31, 1909, and provide the necessary funds for construction of the line from Broken Hill to the frontier in terms of the agreements of July 14 last. This was a great point gained, because it gave this company, for the first time, an opportunity to finance the line itself, for which this company got all it wanted in mineral and other concessions, provided we find the money for the line before Jan. 31 next.

FINANCIAL ARRANGEMENTS

Out of the total amount required to construct the line from Broken Hill to the Star mine, about £1,200,000 has been guaranteed by this company and the Belgian companies we are affiliated with, and the balance is guaranteed by the railway contractors and others connected with them. The Belgian section is to be financed by Belgian capital, and the British section by British capital. All arrangements have been made to form a new company to build the British section, to be called the "Rhodesia Katanga Junction Railway and Mineral Company," and to sell to that company the railway concession to construct and work a line from Broken Hill to the frontier of the Congo state; also the Kansanshi mine and the whole of our coal concessions and rights in Rhodesia. These coal areas are of enormous importance, as they are about 350 to 400 miles nearer the reduction works than any other coal deposit, and a ton of coal will cost 30s. less on railway rates alone, taking 360 miles at 1d. per ton per mile; and Mr. Gibb informs me we can use about 600 tons per day of

this coal for our treatment of the Katanga copper ores. Your company will own shares and debentures in the new company nominally worth about £700,000.

THE INTEREST GUARANTEE

Your company guarantees the interest on the debentures of the new company for 20 years, but the Kansanshi mine itself is producing far more than will cover this interest, and will start with a stock in copper bars amounting to £30,000, which is equal to the first year's interest on all the debentures when the railway can take it away. You are thus in an excellent position—the first line to the great mines of Katanga is assured, and that railway passes close to Kansanshi. We will go on with Benguella railway construction to the plateau, another 80 miles, when that line, according to the report of our resident manager, will commence to have a profit, over all expenses, of £30,000 a year. When the 80 miles are completed the line will be the property of the Benguella Railway Company for 99 years and we should be in position to finance it with ease.

If we have raised, as we have done, upward of £4,000,000 for railways south and west to get at these great copper mines, the Benguella Railway Company will not fail to raise another £1,500,000 to complete the line to the Congo frontier, after we have got at the mines and get profits from our copper. How many companies are there in the world today that have raised £4,000,000, without any returns at all, against every conceivable difficulty, for railways through three different countries and constructed under different governments? We have done this by convincing the different governments, banks and financiers of the value of our assets. Until our own line is completed we shall be paying about £7 more per ton for our copper delivered in Europe than it would cost us by our own line, and we shall be greatly assisting the British South Africa Company; but when our line is completed from the mines to Lobito we shall get the full benefit, and we shall control rates and cost of copper as we please.

We have brought about a powerful combination of finance on clear and well-defined agreements to the accomplishment of a gigantic enterprise. Your capital will be £768,000 issued, with £2,000,000 of 5-per cent. debentures and about £1,000,000 issued with £600,000 worth of debentures if £1,400,000 worth of debentures are converted. If the debentures are not converted we do not pay interest in cash on them for another three years, and even then it will require only £100,000 per annum to pay 5 per cent. on them, whereas if they are converted they would rank as shareholders entitled to a proportion of your profits at any time. With an issued capital of £768,000 and £2,000,000 debentures,

you own 90 per cent. of the Benguella railway, represented by about 2,500,000 fully paid shares, 45 per cent. of the Union Minière Company, and you will also own 700,000 shares and debentures in the Rhodesia-Katanga Junction Railway and Mineral Company.

Black Eagle Falls, Montana

The accompanying illustration of Black Eagle Falls appeared in the program of the 22d annual meeting of the Montana Society of Engineers. These falls are about three miles below the city of Great Falls, where the meeting was held. The power development at this place includes a dam 746 ft. long, placed a short distance above the crest of the falls and giving an effective head of from 42 to 44 ft. There are power houses on both banks, those on

About 12,000 h.p. is developed, the Great Falls Water Power and Townsite Company and the Great Falls Electric Properties taking about 2000 h.p., and the Boston & Montana company the balance.

The Transvaal Stope Drill Competition

SPECIAL CORRESPONDENCE

The final list of entries for the £5000 prize stope-drill competition in the Transvaal shows that fewer applications have been received from non-British makers than previous correspondence and inquiries led us to anticipate. Twenty-three drills have been entered, and it is significant to note that the Gordon hammer drill, which won the competition of last

BLACK EAGLE FALLS, MONTANA, 54 FOOT FACE

the south bank belonging to the Great Falls Water Power and Townsite Company, and to the Great Falls Electric Properties. The water is led from the dam to these power houses through sheet-iron penstocks, and the water wheels are of the turbine type, and of various sizes.

The power houses on the north bank of the river belong to the Boston & Montana Consolidated Copper and Silver Mining Company. The water is here carried from the dam to the power houses by an open canal or head race, the walls of which are of concrete. This head race is 100 ft. wide at the widest point. The available head was originally less than 40 ft., but this was increased by means of a tail-race wall separating the tail race from the main river and delivering the tail water to the river at a distance below the power houses, thus taking advantage of the fall in the river below the shear fall at Black Eagle.

year so easily, is not among them. Nevertheless, hammer drills figure largely on the list. America is represented by only two competitors, in the companies running the "Murphy" and "Waugh" drills; while Germany enters five machines and England 11. The other five are of local production.

British Guiana Mines

Exports of gold from British Guiana for the year ended Dec. 31 were 70,676 oz. bullion in 1907, and 73,089 oz. in 1908; an increase of 2413 oz. The bullion reported in 1908 was equal to \$1,280,948, or 62,407 oz. fine gold.

Exports of diamonds from the colony for the year 1908 were 4008 carats, valued at \$30,872; an increase of \$23,322 in value over the preceding year.

Historical Resumé of the Copper Queen Mine

Bonded at One Time for Twenty Thousand Dollars; Now Valued at Many Millions. The Story of Its Early Struggles and Difficulties

SPECIAL CORRESPONDENCE

Following is a synopsis of an address recently delivered at Bisbee by Dr. James Douglas, president of the Copper Queen Consolidated Mining Company.

In 1876 I was introduced to a gentleman named Riley who had sold a mine in Nevada and was very anxious to come down into Arizona, attracted by the stories he had heard of the famous Ajo mines. I succeeded in helping him to get rid of his Nevada mine, and for some time we kept up a considerable correspondence. Finally, visiting Arizona, the Ajo disappointed him and he went through four years of arduous work looking for something else. At last I heard from him that he had struck a wonderful mine in the Mule mountains. By that time my friend, who was a lawyer of some note, was worn down to where there were hardly any soles to his feet, and he had to borrow money from our friend Zecken-dorf in order to go to San Francisco to float this mine in the Mule mountains, on which he had obtained a bond. Zecken-dorf had the courage to lend him the money; he went to San Francisco and came in contact with the firm of Bisbee, Williams & Co., who knew a firm of engineers by the name of Martin & Barrett. I believe that Martin & Barrett had had some rather ill-luck in railroad contracts and Mr. Martin had been a sworn enemy to all mining speculation; but driven by necessity, determined that they would put what money they had left into the Copper Queen mines. At that time, you know, mines were not valued by millions and the Copper Queen mine was really bonded at \$20,000, on which Martin & Barrett made first payment, taking my friend Mr. Riley as partner.

The mine was opened by a surface cut in August, 1880. The men who started the open cut acted the fool, as most prospectors do; they ran through rich ore at the end of the open cut, and thought it wiser to stop and get what they could rather than spoil the prospect altogether and get nothing, and therefore, the Copper Queen mine was sold for \$20,000.

Mr. Martin came here and employed Lewis Williams, as superintendent, who recommended that he buy the mine. He was subsequently, as you know, succeeded as superintendent by his brother, Ben Williams, whom most of you undoubtedly knew intimately.

At that time, where Main street is now, there was a little spring on what was known as the Malvina claim. I presume

the spring dried up many years ago, though for a time it supplied the only drinking water the town had. The Malvina spring did not yield water enough to supply the 36-inch furnace, and occasionally the furnace had to be shut down. Mr. Martin went east with the view of buying pipe to get a supply of water from the San Pedro river. However, before they got down three hundred feet they struck more or less water in the mine, and that solved and yet solves, the water question.

I came out to Arizona at the end of that year to look at what has since proved to be the Verde mine. At that time the claims were one hundred and eighty miles from the nearest railroad station, and we therefore could not do profitable work; and being disappointed in my visit to the Verde mine, I came down to see my friend Riley at the Copper Queen. That was in 1881, and the Copper Queen was the only mine actually open in the district. It continued from August until January to yield between 20 and 25 per cent. ore and there were no signs of its abating. I could not have thought well of it at that time, because we professional men thought that the limestone was invariably a fake and was simply placed there by Providence in order to delude us. Somehow or other, I have a certain faith in Providence and feel that he does not play jokes, and whenever you find anything that pays as that open cut did it means something very substantial. I took quite a liking to the Copper Queen and told my friend Martin I thought that such an ore-body was not going to be isolated in that fashion, and he said, "We can get it for \$10,000," and I said, "If I were you I wouldn't hesitate to pay the price."

Mr. Martin had made such an admirable strike in the Copper Queen that his whole ambition was to sell the mine for a million dollars—if he could only get a million dollars that was all he wanted, but to buy \$10,000 worth of limestone was simply throwing that much away, and therefore he didn't buy the claim.

BUYS THE QUEEN

The following year I came out on business, and some one said to me, "You know the Copper Queen," and I said "Yes." Then he said, "Yes, they want to sell it for \$25,000," I replied, "I don't think I can sell it, but if I find a purchaser I will let you know." The following summer Phelps, Dodge & Co., for whom I

had done some work, asked me to come out and examine the property. This I did and I gave them the opinion that if they were poor men and it would likely impoverish them to buy it, they had better leave it alone; but if they were in a position to throw their money away, to take it. They took my advice and bought it. The Queen went on working and they got down to the second level, and the third level, and at last got down to the fourth level from the open cut.

When they got there they cut out absolutely clean; there wasn't a trace of ore left on the 400 level. That occurred towards the end of 1884, after they had been working four years. Mr. Martin called in an expert and measured the ore that remained. There was only about three months' supply. The men in the Queen mine, in the meantime, had gone through a most trying time; there were little bits of ore here and there; a few bushels of it on the surface, and that was all, but that didn't mean anything in particular. We tried the west end, went down and found little streaks of ore; then we came to the east end and we followed a streak there which was barren; then we drove a tunnel. The engineers thought they laid that tunnel out correctly, and after we had driven the tunnel we found that it was in clean ground.

By that time the Queen had got us into deep water. There was no more ore, no more money and my friends in New York insisted on going ahead, and asked me if there was anything to go further for; and while I say there was nothing, there was one little, what we called a "joker," leading across the side line of the Copper Queen, and Mr. Williams did not think we had any right to follow it, and I concurred with him. We did not follow it. We were then mining the Atlantic claim, and my friends wanted to know if there was absolutely nothing in it, and I told them that there was one streak of ore that crossed the line, and that it wasn't worth anything itself, but heaven knows what it may lead to. They trusted several thousand dollars more to reach the "joker" and in the meantime after sinking two hundred feet (I expected to go down about four hundred) we struck another glorious body of ore, and just at the same time the Queen ran into the same body.

FORMED PRESENT COMPANY

Then the question arose as to who

owned the ore, and after some discussion of the matter among us, we came to the conclusion it was best to unite our forces, so instead of the Copper Queen Mining company, we formed the Copper Queen Consolidated Mining company in August, 1885, which was a very wise thing, as it has since turned out. There remained to all intents and purposes nothing more in the Queen claim; everything rested in the ground lying south of it. But that was only the beginning of further discouragement.

After the amalgamation, prices dropped, dropped, dropped steadily. We went on working in the same old rattletrap way underneath the open cut. We had two furnaces, each 36 in. in diameter, and as the price of copper dropped profit absolutely disappeared. The value of the ore in the open cut had fallen to about 12 per cent. before they got to the bottom of the first orebody; the average of the other orebody was lower still; somewhere about 10 per cent. but when bar copper dropped to under eight cents it was perfectly clear that there wasn't very much money to be made in working two old 36-inch furnaces. The Queen at the time was very heavily in debt, and I went to my friends in New York and suggested that if we did more economical work we certainly would be able to make a little with copper at eight cents per lb. They were brave enough in the face of all these difficulties to advance the Copper Queen \$150,000 to put up a larger and more economical plant. This was begun in the fall of 1886, and completed in May, 1887. I left New York shortly after we had the meeting to finance the Queen. We were making a trifle, although copper was selling at about eight cents, and I thought that within three or four years we could pay the Queen's debts. Of course, the new works were making considerable more copper and we had to find an outlet for our product.

Just then a Mr. Secretan came to us to make contracts for the whole of our output for three years, we undertaking to give him a certain minimum per month. Mr. Secretan was very generous and offered us about 13½¢ per lb. for our copper. We had been getting 8¢., and, therefore, we proceeded to make a bargain with him. With copper at 13½¢., the Copper Queen debts began to vanish at a very rapid rate and by the following year we were able to pay about \$100,000 dividends; that was a large dividend because we had not received anything for about three of four years. Under Mr. Secretan's regime that dividend increased to \$300,000 a year. But it was later considerably decreased when our production was diminished. However, the Secretan syndicate, as we called it, was a great impetus, and from that time on we began producing ten to twelve million pounds per year. For three years

after the amalgamation virtually the whole of the copper came from the Atlantic orebody as we called it. That body dipped in the opposite direction from the original orebody, but there did not prove to be anything like as much ore as in the original Queen. In 1886 following that same famous "little joker," which I was aiming at in 1884, we came upon what has proved undoubtedly to be the largest continuous orebody that we have ever found in the Arizona country. The stopes of this orebody fed the furnaces for about three years. (Possibly ten or fifteen per cent. of the ore was mined from the Queen.) Meanwhile, we had found an orebody in the west end, so that by the time the southwest stope was exhausted we were finding considerable ore at a greater depth further to the southwest, when an unfortunate change took place in the character of the ore. Sulphide came in and our copper began to seriously deteriorate. It became extremely difficult to sell the 96 per cent. bar copper which we were taking out. Again Providence came to our assistance in the person of a Frenchman, who applied the same treatment to copper which had previously been applied in the making of steel, and that solved the question.

When we commenced mining copper in Arizona, if we had had sulphide ore it would not have paid at all and we would have been forced to abandon it. Since the advent of the new treatment we are re-smelting the old slag dumps that were thrown away in those days.

In 1899 we began handling mixed sulphide and oxidized ores in the first converter, which some of you may recollect. This of course opened up large areas of our ore-bearing ground which we had been prohibited from touching previously by our inability to handle sulphide. From that time the production of the Copper Queen mine rose rapidly to two and three million pounds per month. There was also a little silver in the ore; some of our ores were found to be richer in silver than others and therefore when the Bessemer treatment was inaugurated we devoted one furnace and one converter to the smelting of silver-bearing ore.

All these things, in the process of development from small days to days of large events and larger quantities compelled us to move our smelters out of Bisbee. It became impossible to extend the plant in proportion to the expansion of the mines and the mines had expanded by the absorption of other property.

I was telling you about the hard times in the Queen's history. During that period they were offered two claims called the Holbrook and the Cave. They were owned by a Mr. Garnett, who at one time intended to work, but decided to sell them for what he thought the property was worth. Mr. James and Mr. Dodge bought them. We worked the Holbrook

and the Cave for quite a number of years as independent operations, in fact, until the year 1892. They used to produce about sixteen to seventeen million pounds.

COL. HERRING'S CLAIMS

There was a member of the bar, Colonel Herring, who had the mining fever, and located a group of claims on the other side of the mountains. He had the Dividend, the Neptune and several others. When I came out early in 1881 I found a certain man who was a mineralogist and geologist, who was superintendent of those claims. He was more than half-hearted about them. He was absolutely pessimistic. He said the ore was in limestone and simply worthless. Anyhow, the Dividend company put up their furnace at Helfa and hauled their ore down there to smelt. The company, however, came into existence through our friend Colonel Herring. Colonel Herring's brother, who located the claims, died and the colonel started in to wind up his estate; he gave up the profession of law in New York, went back again, organized a company, and came out here as the manager of it. When I came out here in 1881 I found Colonel Herring living in what was called the "Castle," a great big *adobe* house under the cañon.

They spent the whole of their capital stock and about \$80,000 of bonded indebtedness; the people who owned it got sick of it, and put it up at sheriff's sale. We bought it. However, the Holbrook, Cave and Dividend were turned over in 1892 for a slight increase in the capital stock of the company. Originally, the capital stock of the Copper Queen was two million dollars; and when the consolidation was effected, instead of adding a few million more, Mr. Dodge, who was very peculiar about those matters, thought that the capital ought to be cut down to one million four hundred thousand. When this other property was bought, including the Holbrook, Cave and Dividend, the whole group was turned in for \$600,000, so the capital of the company was again up to two million dollars. However, after the amalgamation and after the introduction of Bessemer treatment, we moved the works down to Douglas, because there wasn't room to expand up here in the narrow quarters which were assigned to the works.

It became at once evident that it would be difficult for us to carry on a large enterprise without transportation facilities. We therefore built a railroad from Benson to Bisbee, and later this was extended to Douglas. Our railroad would probably have ended there, if it hadn't been that we bought a mine from the Guggenheims at Nacozari. Afterward it was decided, on account of some difficulties which we were compelled to surmount, and in order to afford us a better outlet for our products, to build our line in to El Paso.

Mine Explosions as Related to Earthquakes

A Discussion Favoring the Theory That the Danger from Explosions in Deep Mines Is Augmented During Periods of Seismic Unrest

BY W. A. SPALDING*

In the JOURNAL of June 1, 1907, Prof. James T. Beard discussed the subject of mine explosions, and their connection with seismic disturbances. Every observer must have noted that disastrous explosions in mines seem to come in series, and when one occurs in any field several others in various parts of the world are apt to follow in close succession. Then may come a cessation of such disasters for a considerable time, to be followed by another series. Have these intermittent seasons of mine explosion a sort of periodicity? That is, are the antecedent conditions of gas accumulation which invite disaster, periodically recurrent, and if so, has this condition any connection with seasons of seismic and volcanic activity?

Professor Beard believes that internal pressure is the cause of larger, spasmodic emissions of gas. He states that even in districts producing large quantities of gas and which, therefore, appear to furnish a constant emission, there is a very perceptible ebb and flow, causing periods of fluctuations in the gaseous condition of the mine. He says:

"In other districts and mines, there are corresponding periods in which much gas is given off, followed by intervals when there is almost an entire absence of gas in quantities to cause alarm. Often these periods of the ebb and flow of gas from the strata are quite local; that is, restricted to a limited area or district, and at times appearing in a single mine or portion of a mine only. Several instances have recently occurred where the flow of gas increased in a portion of the mine so rapidly that the men were withdrawn from that district and not permitted to return for nearly a month, when the flow ceased almost entirely."

INTERNAL AGENCIES

Such observations as the above induced Professor Beard to turn his attention to internal agencies, and seismic and volcanic action naturally came in for consideration. Again quoting from his article:

"We possess very little exact knowledge of the condition of the interior of the earth, but the evidence of volcanoes in action and our knowledge of the agency of heat and pressure makes it certain that tremendous activities are in constant operation within the earth's sphere. It is both natural and reasonable to suppose that the pressures in subterranean channels

that will discharge molten material under a great head, can make themselves felt in other quarters, and incidentally augment the outflow of gas from strata already pregnant. No one familiar with underground conditions and who has listened with awe to the mysterious 'poundings' in the overburden of a mine, caused, as is well known, by the working of gas in the foliations of the strata, can study the phenomena of earthquake waves and shocks without being convinced of the close relationship of the different phenomena. The conclusion is fairly certain that gas generated by the chemical and physical activities within the earth plays an important part in all these phenomena.

"The theory of spasmodic or irregular earth breathings, as just explained, if true, would give rise to periods of frequency of mine explosions, more or less closely associated with volcanic activity. That such is the actual fact is shown to be highly probable by the remarkable coincidence in their occurrence. That there are isolated or errant mine explosions occurring in a period of rest and entirely dissociated from seismic disturbances, does not argue against the theory, since it is not claimed that all mine explosions are the result of such disturbance. The causes producing explosive conditions in mines are too numerous to invite such an expectation. But when periods of marked seismic troubles are almost invariably accompanied by the appearance of gas in increased quantities in mine workings, and the occurrence of one or more mine explosions, the fact is significant of something more than mere chance."

THE VALUE OF A STATISTICAL STUDY

Professor Beard then gives a list of concurrences between seismic and volcanic action on the one hand and mine explosions on the other. At first glance such a statistical comparison would seem to be somewhat unscientific and far from convincing. To institute a satisfactory comparison, we must have a basis of similarity in the things compared. Earthquakes and volcanic eruptions are purely natural phenomena. Mine explosions are only natural insofar as they depend on the antecedent collection of gas in subterranean cavities; the ignition of the gas is accidental, and depends on human agency. Every reasonable precaution to prevent such accidents has been adopted by mine operators; chief of which are the frequent inspection of deep workings, to

detect the presence of gas in dangerous quantities; the ventilation of such workings by proper openings and forced draft, and the use of safety lamps. But these precautions, while theoretically correct, are not perfectly executed; hence an occasional explosion occurs involving loss of life and destruction of property.

If we could have for the purpose of our comparison full statistics of the ebb and flow of gas in mines, it would be far more satisfactory than to deal with those exceptional and largely accidental cases involving disaster. But such full statistics are not generally kept, and the compilation of a sufficient record would require years of constant observation in a large number of mines. Hence, for the present, we must be content with such values as may lie in the natural conditions antecedent to explosions which make the events matters of record.

Under the exigencies of the case, it would be folly to trace the line from cause to effect, starting with natural phenomena which would produce the specified antecedent conditions, and then expect each series to find its logical conclusion in a mine explosion. Our method should rather be inductive—from effect to cause. Given, a mine explosion; the condition of gas accumulation must have been present; now can we trace this condition back to a natural phenomenon, such as an earthquake or volcanic eruption, occurring about the same time? Hence, we should not attempt to find a mine explosion for every seismic or volcanic disturbance, nor yet an earthquake or an eruption for every mine explosion, but such concurrences as we do find should be carefully studied. With the foregoing thought in mind, I have rearranged Prof. Beard's list to present it in a more graphic form and have augmented it somewhat by inserting data gathered from other sources:

TABLE SHOWING CONCURRENCE OF MINE EXPLOSIONS AND SEISMIC DISTURBANCES.

Mine Explosions.	No. Killed.	Seismic and Volcanic Disturbances.
	1896.

it challenges consideration. The following fundamental conclusions are obvious:

1. That a seismic convulsion is due to great stresses or strains acting upon the crust of the earth.

2. That the fracture and displacement of strata open up fissures through which gases may escape as the result of internal pressure.

3. That a subterranean explosion producing a volcanic eruption must be accompanied by a lateral and backward pressure equal to that which projects the material from the crater.

4. That with seams in the surrounding strata opened by earthquake shocks, and a great lateral pressure from a subterranean explosion or other cause, gases may be driven to great distances.

5. That such gases may be discharged through fissures into deep mines, and accumulate in the chambers to such an extent as to invite disaster.

As Professor Beard observes: "Because two occurrences or phenomena are of record almost invariably contemporaneous, proves no more than the fact of their association. It remains to be shown whether the association is one of cause and effect, or whether they are both alike the effort of a hidden cause as yet unknown, perhaps unsuspected."

However, in the case under consideration, the cause and effect seem to be closely united on theoretical grounds at least, and the close association empirically shown, while not conclusive, is nevertheless entitled to due weight.

SEISMIC DISTURBANCES ARE NOT LOCAL

It may be objected that volcanic eruptions and seismic shocks are, in a sense, local phenomena; that the principal effects are restricted to a definable area, including the volcano or the epicentrum of the earthquake. Yet it is true that by aid of the seismograph, a tremor from a heavy tectonic earthquake may be traced around the world, showing that at least a secondary effect—a vibration of the earth's crust—is general.

There has been a movement among the more advanced seismologists, of whom the late Professor Heilprin was a representative, to attribute a much closer connection between volcanic eruptions and earthquakes than was formerly conceded, even when the two classes of phenomena are widely separated. An inquiry as to whether there could be any association between a violent outbreak of Vesuvius and an earthquake in San Francisco, both occurring at nearly the same time, would not be flouted by an up-to-date investigator. We are still too far from a satisfactory demonstration of the prime causes of seismic and volcanic disturbances to allow, in such case, much weight to a dogmatic disclaimer.

While this article was in preparation there came two striking confirmations of Professor's Beard's theory: March 26, 1908, occurred a severe earthquake in Central Mexico, damaging buildings in that city, destroying the town of Chilapa and causing great destruction of life and property. March 28—two days later—we note a disastrous explosion in the No. 1 mine of the Union Pacific Coal Company at Hanna, Wyoming, in which 70 men lost their lives. As an interesting side light on the question under discussion, the following associated press despatches are worthy of notice:

"Beloit (Wis.), March 19, 1908. The roaring well on the Charles Lathers farm northeast of Beloit, sounds from which preceded the San Francisco disaster, is again emitting rumbling noises and a strong wind from its cavernous depths. It is asserted that this well began roaring a few weeks before the San Francisco earthquake, and ceased at exactly the hour of the quake."

"Beloit (Wis.), March 27, 1908. The famous "roaring well" has again made good. March 19 it was found that the phenomenon, on the farm of Charles Lathers, northeast of this city, was active. The well roared for several weeks before the great earthquake at San Francisco, and the curious sound of rumbling, together with wind from the mouth of the well, ceased at the precise hour when the shock struck the California city. When the well resumed its clamor last week residents of Rocky county predicted a calamity. Yesterday it came—in Chilapa, Mex.

Beloit, Wis., is far removed from San Francisco, yet it appears that there was some sympathetic connection between the roaring well and the earthquake in the latter place April 18, 1906. Again, a still greater distance intervenes between the roaring well and the City of Mexico, yet the phenomenon is repeated March 26, 1908. Such sympathetic action can only be accounted for on the theory of a general stress upon the earth's crust preceding and concurrent with seismic action. I may also add that through personal correspondence with the owner of the well above mentioned, and with reliable citizens of Beloit, Wis., I have confirmed the truth of the press despatches just cited.

AN ANALYSIS OF THE FOREGOING TABLE

The concurrence or close approximation between earth disturbances and mine explosions noted in the foregoing table certainly gives color to the theory that the danger in deep mines is augmented during periods of seismic unrest. When such a theory is abundantly supported by reason,

Miners Convention Adjourned

The convention of the United Mine Workers of America, after three weeks of turbulent deliberations in Indianapolis, Indiana, adjourned late Saturday night, Feb. 6. The sessions of the last week dragged along in a manner characteristic of the entire convention and were marked by the customary wrangling. There was scarcely a report made during the convention that did not create some factional disturbance. A resolution was passed providing for the amendment to the by-laws which it is hoped will enable the organization to elect officers without the taint of fraud, and also for the expulsion of any official, candidate or member guilty of making or circulating false statements against one another.

Before the convention adjourned a more friendly feeling was manifested between the factions and the vote of thanks to President Lewis was not opposed.

The scale committee which had under consideration the situation in the anthracite district of Pennsylvania made its report recommending the adoption of the wage scale agreed upon by the anthracite districts at a conference held at Scranton, Penn. last fall, as follows:

"1. That an agreement shall be negotiated between the representatives of the miners and operators of the anthracite region, and all disputes arising under the contract shall be adjusted as provided for in said agreement.

"2. We demand the complete recognition of the United Mine Workers of America as a party to negotiate a wage contract, and that the United Mine Workers of America shall be recognized in our right to provide any method we may adopt for the collection of revenue for the organization.

"3. That we demand an eight-hour day with no reduction in wages.

"4. That all coal shall be mined and paid for by the ton of 2,000 pounds.

"5. That we demand a definite and more uniform scale of wages and prices for all classes of labor at all collieries in the anthracite region; and that all employees paid \$1.50 or less per day shall receive a 10 per cent. advance and all employees paid more than \$1.50 and less than \$2 per day shall receive a 5 per cent. advance.

"6. That the system whereby a contract miner has more than one job or employs more than two laborers be abolished.

"7. That the employers be required to issue uniform pay statements, designating the name of the company, the name of the employee, the colliery where employed, the amount of wages and the class of work performed.

"8. That the contract shall be made for a period of one year."

The committee recommended that the officers of the Mineworkers' organization use their best efforts to bring about a conference with the operators and left the details with the executive committee.

The convention concurred in the report.

On account of the cost it was decided not to send a representative to the International Mining Congress in Europe next year. A number of facetious speeches were made by President Lewis, J. P. White, W. D. Ryan, E. S. McCullough and others previous to adjournment.

The newly elected officers are: President T. L. Lewis, Vice-President, E. S. McCullough; Secretary-Treasurer Edwin Perry.

Indianapolis was again selected as the place of holding the convention next year.

Pocahontas Consolidated Collieries Company Merger Sustained

An important decision in favor of the Pocahontas Consolidated Collieries Company, Incorporated, was rendered by the U. S. Circuit Court of Appeals at Richmond, Va., on Jan. 16, in the case styled *Campbell vs. Jones*, affirming the decision of the lower Federal court.

It will be recalled, as reported in the JOURNAL last January, that this suit was brought by the dissenting minority holders of the \$300,000 of the preferred stock of the Pocahontas Collieries Company, which was merged with and under the name of the Pocahontas Consolidated Collieries Company, Inc., on July 1, 1907, under the Virginia Corporation Act.

The new or merged company issued \$6,000,000 of 50-year 5-per cent. bonds, \$2,800,000 of preferred stock, and \$4,520,000 of common stock, upon the combined properties of the company located in the Pocahontas coalfield in Virginia and West Virginia.

Under the plan of merger the preferred stockholders of the Pocahontas Collieries Company were to receive in exchange for this stock \$1,500,000 of the new bonds. All the securities of the several companies merged were exchanged in accordance with the plan of merger except the \$300,000 of this preferred stock of the Pocahontas Collieries Company, and the holders of these shares of stock attacked the merger on the ground that they did not wish to exchange their stock for a 5-per cent. bond, and asked the courts to set aside the merger.

The case was heard in Lynchburg, Va., in June, 1908, in the United States Circuit Court of the Western District of Virginia, and a decision rendered in favor of the company, dismissing the suit, from which an appeal was taken, the result of which was the decision as above men-

tioned, affirming the decision of the lower court. The effect is, to remove any question as to the validity of the securities issued under the plan of merger, and the decision is important, in that it is the first large merger that was made under the Virginia Corporation Act, which act is also sustained by this decision.

Rescue Apparatus in Austrian Mines

Among the amended regulations issued by the Austrian Mining Board is an interesting provision relative to the use of rescue apparatus. This regulation states that some approved form of rescue apparatus shall be kept in working order, and in a readily accessible place at all mines. In order to keep the valves and fittings from being attacked by rust, the oxygen bottles must be perfectly dry inside, and recharged with dry oxygen by a dry pump. A bypass valve must be provided for use if the reducing valve gets out of order. In the most dangerous class of mines, the prescribed number of sets of rescue apparatus is as follows: Five when not more than 200 men are at work per shift, 10 for shifts working from 200 to 400 men, and 15 for shifts of over 400 men. Each apparatus must be able to supply oxygen for 1½ hours at the minimum. Where the mines are less dangerous and belong to the nonfiery class, the number of apparatus is fixed at five, irrespective of the number of men per shift, except that where these are below 200, a smaller apparatus—supplying enough oxygen to last for an hour—is permitted.

Where a number of dangerous mines, employing over 200 men per shift, are situated close together, all the apparatus in excess of the five sets necessary for the equipment of one corps of rescuers may be kept at a central depot of easy access from all mines. Rescue stations must be furnished with a duplicate source of oxygen bottles, and a number of safety lamps of some permitted type; one oil lamp for testing the presence of firedamp is necessary when the other lamps are electric. A trained deputy must be placed in charge of the station and made responsible for the good order and maintenance of the equipment. The men trained for rescue parties must be medically examined, and each corps must use the apparatus at least every six months, the results of practices being entered on official forms, together with those of the examinations of the apparatus, etc., at regular intervals.

The cost of mining at Mount Lyell mine, Australia, for the six months ending Sept. 30, 1908, including cost of removing overburden, was 6s. 9d., or \$1.62 per ton.

Colliery Notes

A shot-firer should not charge any shot-hole until he has thoroughly examined all accessible places within a radius of 60 ft. from the shot.

There is so little known as to how the elements are combined in coal that many fuels of the same apparent composition produce entirely different results when subjected to combustion.

Should a shot misfire and after a sufficient lapse of time, the shot-firer decides to authorize the workmen to drill another hole, it is most important to see that the second hole is located at a distance not less than 12 in. from the misfire.

There are but few cases where a superintendent is justified in erecting dams to keep back gas in old workings; if an explosive mixture is shut off in this way, it must be so effectively dammed back that the gas will not assist in furthering any future explosion. The safest method of dealing with all accumulations of gas whether in old or new workings is by efficient ventilation.

As a general rule, a coal-cutting machine requires a space of 4 ft. clear from the face, so that it may work continuously and without danger of being buried; for this reason, many superintendents advise against the adoption of coal cutters in a mine where the roof has a tendency to fall. It may be stated in this connection, however, that mining machines are now being successfully used under a bad roof, the timbering being done from behind.

Firing shots with a covering of paper, waterproofed with wax or other inflammable material, is a doubtful practice. It is, of course, necessary to preserve the explosive from dampness while it is being stored; however, this could easily be accomplished by having two coverings, the inner one of non-inflammable material, and the outer one of damp-proof paper; the outer cover should, therefore, be removed immediately before the shot is inserted into the shot-hole.

A sinking shaft may be satisfactorily ventilated by employing a small blowing fan 4 or 5 ft. in diameter; the mouth of the fan is connected to a column of 15-in. diameter circular galvanized air pipes, these pipes being conducted from the fan to within a few yards of the bottom of the sinking shaft. The ventilator is driven by belting from an engine. One end of every pipe should be tapered so as to fit into the end of the next pipe, and the two sections can then be attached to each other by bolts passing through lugs riveted on each end of every pipe. The pipe column can be suspended in the shaft by stays located 18 or 20 ft. apart.

When the water in a steam boiler is dangerously low, the first precaution is to close the draft and bank the fire with ashes or damp earth. After awhile, if the boiler has cooled and the fire been made "dead," the fuel may then be withdrawn if the operation can be performed without increasing the heat. The safety valve must not be opened with the mistaken object of decreasing the steam pressure, for just as much steam as escapes will again be generated and add additional dangers by further decreasing the supply of water that remains in the boiler. If, when the evil is discovered, the engine is stopped, the recoil of the steam is likely to form a serious danger; it is advisable, therefore, to keep the engine running until the danger has been somewhat lessened. A further precaution is to avoid starting the feed pump, for should this be done, the overheated plates are liable to snap when suddenly cooled.

When a miner or other workman receives a severe electric shock rendering him insensible, remedial measures should be persevered with until a medical man has pronounced life extinct. A victim subjected to a severe shock often exhibits symptoms that cause observers to conclude life extinct; however, death should not be assumed. One recent case occurred where a workman received a 2000-volt shock from hand to hand, but was not badly burned; the man was insensible, and those present could not feel his heart beating; his eyes were turned up so that only the whites could be seen, his jaw dropped, and his breath did not cloud a mirror. The victim, to all appearances, was dead, but after 45 min. artificial respiration the man recovered. It is almost certain that in the earlier days of electricity, many people were given up for dead after receiving an electric shock when they might have been restored by the immediate application of artificial respiration.

Every mine should have a fixed rule making it necessary for a workman to first secure permission from the manager or superintendent, before being permitted to fire shots upon any main haulage or air roads, up to a stipulated distance, say 50 yd. from the face. The reason for this precaution is that haulage-roads and airways generally hold an accumulation of very fine dust due to the passage of loaded cars and the tramping of miners going to and from work. The high velocity of the air current in these main entries causes the smallest particles of dust to be located in the roof, sides and floor, and creates a more dangerous condition than exists at the face of entries or chambers. The mine manager is not taking too great a precaution, should he go still farther and require that all shots of this kind should be fired between shifts, or at night when all men except the shot-firers are out of the mine. If such shots are fired by electricity, the

cable should be from 45 to 50 yd. in length, so as to enable the person who fires the shot to be out of reach of the flying stone.

An English company has installed a 2000-kw. steam turbine mounted on a special rubber foundation, which latter has been introduced to obviate any possibility of vibration. The turbine set is bolted to a special slab of concrete about 2 ft. thick, reinforced with a steel grid and supported by a series of circular rubber stools, which rest on the ordinary concrete built into the ground. The top of the floating concrete slab is level with the engine-room floor, but the edges do not come in contact with the floor, so that there is no connection between the concrete slab to which the turbine set is bolted, and the foundation, except through the rubber. This eliminates the possibility of vibration due to the reciprocating engines which are located nearby. As a further precaution in this unique installation, a trench is provided around the floating slab so that the rubber stools can be inspected. Each rubber stool is a cylinder of about 4 in. in diameter and 3 in. in height when compressed by the weight of the turbine set. The rubber stools are all separately renewable, and can be withdrawn and reinserted by further compressing them, by tightening of the "jacks" in which they are held by means of screws. This is the largest turbine ever mounted in this way.

Since the Royal Commission appointed to investigate the life of the coal supplies of England, reported that the fuel beds of that country would not last more than from 500 to 800 years, the chief scientists of Great Britain have been theorizing as to what source of energy they can turn when the coal supply has been exhausted. The oilfields are already showing a decreased production, and the water power in Europe is estimated not to exceed 2,000,000 h.p., while the industries of England are expending approximately 100,000,000 h.p. at the present day. The extraction of power from the tides as well as the use of engines worked by solar heat are ideas of doubted value. The only possible alternatives, according to Sir William Ramsey, are to either obtain a supply of heat in the form of steam by drilling a hole in the earth's crust at least 10 miles deep, or to extract energy from the ether. As to the extraction of steam from deep drill holes, Mr. Parsons, of turbine fame, states that execution of such a project would cost \$25,000,000, and could not be accomplished in less than 80 years. The best scientific opinion also asserts that the possibility of a discovery to extract energy from ether is highly remote; it therefore appears that for all practical purposes the scientific world is unable to dethrone King Coal from his enviable position as the greatest necessity of man.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, PRES. AND TREAS. ROBERT MCKEAN, Sec'y.
505 Pearl St., New York.

London Office: 6 Bonerrie Street, London, E. C., Eng.
CABLE ADDRESS: "ENGINEERING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs. Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for January, 1909, was 54,000 copies.

February 6.....	12,000
February 13.....	10,000
February 20.....	10,000

None sent free regularly, no back numbers. Figures are live, net circulation.

Consumption of Copper in 1908

The statistics of the Copper Producers' Association enable us to approximate the deliveries of copper in the United States in 1908, for which in our issue of Jan. 9, 1909, we reported "no reliable data available." The table may now be completed as follows:

	1907.	1908.
Stock Jan. 1.....	9,000,000	120,000,000
Imports of refined.....	5,000,000	None
Production.....	1,152,747,890 (e)	1,105,000,000
Total supply.....	1,166,747,890	1,225,000,000
Exports.....	508,929,401	661,876,127
Remaining in U. S. Dec. 31.....	657,818,489	563,123,873
Stock Dec. 31.....	120,000,000	122,357,266
Delivered for consumption.....	537,818,489	440,766,607
(e) Computed as per footnote, JOURNAL, Jan. 9, 1909, p. 56.		

The delivery for consumption in 1908 appears therefore to have been about 82 per cent. of that in 1907, and 66 per cent. of that in 1906. The basis for comparison is well established, our own statistics and those of the Geological Survey for 1907, each computed from data collected independently, having been in close agreement, our own figures with those of the Geological Survey in brackets having been as follows: 537,818,489 (\$45,000,000).

While the production of crude copper increased in 1908 about 70,000,000 lb. that of refined is computed to have decreased about 48,000,000. This was because the refineries were operating at reduced capacity in the early part of the year. The increase in the smelting production overlapped into 1909 as is clearly shown by the refinery production of 112,135,200 lb. in January. Even if the smelters should now restrict operations the refinery output would continue at substantially undiminished rate for nearly two months.

Some criticism has been directed against the association statistics of stock on hand on the ground that they do not disclose the whole quantity of merchantable copper. We understand, and believe, that they do—including the Lake, electrolytically refined, and the bessemer bars that are sold for casting—being in fact all of the merchantable copper in first hands, whether sold or unsold, excepting that which may be in the hands of smelters of scrap and junk—probably a very small amount. An insignificant quantity may also be in second hands.

The swelling of the figures of the copper accumulation by adding the copper in transit and in treatment at the re-

fineries is deceptive, because about two months' production must always be in that state. It would be quite as logical to go further back and reckon the copper in ore awaiting treatment at the smelteries of which there were some large reserves on Jan. 1.

Because the delivery for consumption in 1908 appears to have been about 440,000,000 lb., it does not follow that consumption was so large, inasmuch as the manufacturers probably had stocks in their yards. The large deliveries in January were to a great extent the filling of orders placed in November. Of course, no one believes that consumption was going on at the rate of nearly 600,000,000 lb. per annum in January. The inference is obviously that the requirements of manufacturers are still well provided for, which explains the small sales in February so far and prepares us for the report of a further accumulation of stock, the shipment of the November sales approaching completion.

If the price for copper should become attractive to the manufacturers so that they would transfer the whole, or a part, of the present stock to their yards, the producers would be relieved, but after all we must look to the final consumer who takes the metal out of the market and puts it to use.

Earthquakes and Colliery Explosions

It is proper for us to remark that the suggestive article by Mr. Spalding, which appears in this issue, was written many months ago, and if he had had an opportunity to revise it, he would have been able to make some important citations from recent experience. It is well known that the period of great seismic disturbances, culminating with the catastrophe in Italy last December, has been accompanied by an unusual number of colliery explosions. An argument on the basis of *post hoc ergo propter hoc* is inconclusive. Nevertheless, it must be admitted that the coincidence between earthquakes and colliery explosions is such as to warrant careful study of the conditions. In this connection, full credit must be given to James T. Beard, who has for many years been drawing attention to this matter, as the readers of the JOURNAL are well aware.

The subject has now become one that is attracting international attention. Our Paris correspondent, in his letter in this issue, remarks that M. Moreux, manager of the observatory at Bourges, is an exponent of the earthquake theory. Of equal importance is the suggestion made before the Meteorological Congress, recently sitting at St. Petersburg, where it was pointed out that oscillations of the earth frequently cause the escape of gas in mines. This led several delegates to suggest that a seismograph be installed at every mine to record the least earth movement and thereby warn the engineers of the possibility of danger.

This, together with the atmospheric theory, that we have previously discussed, continues to demand the careful attention of colliery engineers. Our propaganda as to the probable effect of atmospheric conditions has led many operators to install barometers at their mines and observe them carefully for warning of approaching low pressure. Such warnings are generally recognized in Europe as being of great practical benefit.

Two Efficient Colliery Safeguards

We have remarked some scores of times that there is no great mystery about colliery explosions, which are not "acts of God," but rather are due to the carelessness of men. The greatest safeguard against them is obedience to the laws and eternal vigilance. However, it is human to err and perfection is not to be expected as long as there is a personal equation. What the engineers and investigators are really aiming to develop is a system of safeguards which by application will make a "fool-proof" mine. In this connection engineers are directing their attention principally to the control of shot-firing and to methods of underground sprinkling. Mr. Harrington, formerly chief engineer for the Utah Fuel Company, has written an admirable discussion of these two safeguards. In the JOURNAL of Jan. 23 was published his article on "Spraying Coal Dust," while the JOURNAL of Jan. 30 contained an article on "Shot-firing." We consider these articles to be a highly important contribution to knowledge as to their subjects, both of them being distinguished by an eminently practical character.

It is doubtful if any other coal company in America has applied these systems so thoroughly as the Utah Fuel Company, and it is, therefore, important to learn that after years of experience the officials of that company heartily indorse the installation of similar systems in all coal mines.

A complete spraying system as outlined by Mr. Harrington costs approximately \$7000, which expenditure if distributed over a year would amount to about $2\frac{3}{4}$ c. per ton at a mine where the annual production is 300,000 tons. If the same outlay were distributed over a period of five years, the cost would be less than 0.5c. per ton of product. The total operating cost of this spraying system amounts to less than 1c. per ton. The cost of installing a shot-firing system like the one described in Mr. Harrington's second article is about \$1250, which, if paid by one year's output at a mine producing 300,000 tons annually, would add but 0.4c. per ton of product. The annual operating cost of this latter system does not exceed \$1000, according to Mr. Harrington's figures, which would increase the cost of coal about $\frac{3}{4}$ c. per ton. At other collieries the cost has been found to be a little more than that, but even so, it is insignificant in comparison with the advantage gained.

The greatest objection from mine operators to such systems as those suggested has been the increased cost of coal. Now that actual figures are placed before us, there remains no reason for doubt on this score. Many coal-mine managers, whose properties are in bad condition, are at present making much noise in promoting the notion that our so-called ideal mines have been the ones lately visited by serious disasters. It will not be surprising if the same individuals soon claim that a well planned, carefully operated mine is the very one to be shunned as dangerous to the welfare of the mining industry. Of course, those who have planned and developed ideal mines should be commended for their enterprise and condemned only for having overlooked the personal factor of neglect and carelessness on the part of individual miners.

If a blown-out shot should cause an explosion in a mine after all of the employees have reached the surface, it is certain no human lives would be destroyed. It is also indisputable that dust explosions, from whatever cause,

cannot well occur in workings where the fine coal is reduced to a point of saturation. Consequently, it appears that the precautions suggested by Mr. Harrington are the proper measures to perfect and make our so-called ideal mines really safe.

The time is fast approaching when miners will be punished for violations of rules, and mine officials will be compelled to prove that they are really guiltless in event of a serious disaster. On Jan. 25, a mine superintendent and foreman at Wilkes-Barre, Penn., were found guilty of negligence which resulted in two disasters, one causing the death of 12 and the injury of 13 men, and the other the death of six and the injury of five miners. Although the judge who rendered the decision suspended sentence, declaring that the conviction will serve the ends of justice and carry with it its own punishment, the incident is interesting because it lends hope to the desire that justice be meted out equally to all.

American Smelting and Refining Company

The statements made in the application of this company to the New York Stock Exchange for transfer from the unlisted department to the regular list includes some interesting technical data, although these appear to have been somewhat carelessly prepared. Of course the attention of the committee of the Stock Exchange is directed chiefly toward the financial details, as to the accuracy of which no question is here raised.

According to the statement of the company, its present smelting capacity is 4,465,000 tons of ore per annum. Of this, 1,600,000 tons is in the live Colorado plants, five in number. (However, we believe, that all of the Colorado plants, including the Grant and the Philadelphia, that are now shut down, have never smelted more than 1,000,000 tons of ore per annum). The smelting capacity in Utah is 523,000 tons, which of course does not include that of the Garfield works, belonging to the Securities Company. The capacity in Montana is 235,000 tons. The three Mexican plants are able to treat 1,333,000 tons, while the El Paso works, which is to be considered both as an American and Mexican plant, has a capacity for 492,000 tons. In connection with the refineries at Omaha, Chicago and

Perth Amboy, there is a smelting capacity for 282,000 tons.

The company says that "The actual amount smelted has averaged about 3,500,000 tons annually." That is decidedly a vague statement and leaves much to guess. However, it is the first time that the company has ever given any indication of the amount of ore smelted. We guess that 3,500,000 tons may be close to the amount smelted in the year of banner profits, viz., 1906-07.

In an article in the JOURNAL last summer, it was estimated that the amount of ore smelted in 1902-03 was probably about 2,500,000 tons, on which basis, the net profit to the company was a little less than \$2.20 per ton. Assuming 3,500,000 tons for the amount smelted in 1906-07, the profit in that year was \$2.83 per ton, which of course includes not only the profits in smelting directly, but also that from the various commercial and mining enterprises of the company and the gain upon metals in hand arising from a strongly advancing market. However, as we have previously pointed out, the income account of the Smelting Company does not allow, in our opinion, as much as necessary for amortization of plant, and probably actual profits are less than will appear from any way of figuring.

Pig Iron in 1908

The complete statistics of pig-iron production in the United States in 1908, as collected by the American Iron and Steel Association, show a reduction of 38 per cent., as compared with 1907, the heaviest proportional loss for many years. The production last year was less than two-thirds of that of the preceding year, and was only a little above that of 1901; being less than that of any intervening year. The make was only about one-half of the total capacity of the furnaces.

The division according to the purposes for which the iron was intended is as follows:

	1907		1908	
	Tons.	Per Ct.	Tons.	Per Ct.
Foundry & forge	5,397,777	24.8	4,307,734	27.0
Bessemer pig....	13,231,620	51.3	7,216,976	45.3
Basic pig.....	5,375,219	29.3	4,010,144	25.2
Charcoal iron....	437,397	1.7	249,146	1.5
Spiegel and ferro	330,348	1.3	162,018	1.0
Total.....	25,781,361	100.0	15,936,018	100.0

Steel-making irons were 73.5 per cent. of the total in 1907, and 71.5 in 1908; indicating that the demand for foundry pro-

ducts decreased in a slightly less proportion than that for finished steel. The most interesting point of comparison is the increased proportion of basic pig made last year.

The production of pig iron apportioned by districts was as follows:

	1907.	1908.
N. England, N. Y. and N. J.....	2,052,060	1,258,661
Pennsylvania.....	11,346,549	6,987,191
Ohio, Ind., Ill., Mich., Wis. & Minn.....	8,467,045	5,050,303
Maryland.....	411,833	183,502
Southern states.....	3,033,388	2,143,220
West of the Mississippi.....	468,486	313,071
Total.....	25,781,361	15,936,018

This classification is based chiefly on ores used. It is not possible to make an exact division in the report by States, but the errors will nearly balance. Thus the New York furnaces which use Lake ores offset those in eastern Pennsylvania which use local ores. Maryland production is largely from imported ores. The table shows that approximately 75 per cent. of the pig iron made in 1908 was from furnaces using Lake Superior ores, and 13.5 per cent. in Southern furnaces. Over 88.5 per cent. of the raw material came from those two districts.

Perhaps the only encouraging feature of the statement for 1908 is that the second half of the year showed a gain of 2,100,010 tons, or over 30 per cent., over the first half. This is a sign of improvement in business; but 1908 will stand out—for a long time, let us hope—as a pre-eminently lean year.

The Anti-Japanese Turmoil

The hostile legislation by some of the States on the Pacific coast against the Japanese appears now to have been side-tracked through the efforts of the Federal Government, but inasmuch as the projects discussed at their present sessions were but the recurrence of previous agitations, it is to be feared that the snake has not yet been fully scotched. It is time for the engineers and business men of the Pacific coast, as well as elsewhere in the United States, to think over what this thing means. At the last meeting of the New York Section of the American Chemical Society, when Dr. Baekeland announced his marvelous discovery of bakelite, Dr. Takamine, the eminent Japanese chemist who resides in New York, spoke feelingly as to the present attitude of America toward his country. He was, of course,

promptly assured that it was not the attitude of America, but of only a small portion thereof.

Nevertheless, the agitation of these trouble-makers is undoubtedly having an adverse effect upon our commercial relations with Japan. Prominent Japanese residents in this country, as well as Japanese engineers visiting here, have called attention to the likelihood that, unless the repetition of such agitation be stopped, our important trade relations with Japan will be injured. While the intelligent class of the Japanese may understand that the agitation is local, yet it is feared that persistence in it will eventually engender ill feeling between the people of both countries and undermine the amicable relations that have heretofore existed. It is, of course, difficult for the foreigner to draw a sharp line between the Americans in California and the Americans in other States.

Indeed, we understand that orders for material contemplated for this country have already been placed in Europe. Our business with Japan in railway material, mining machinery, manufactures of iron and steel and other articles amounts to many millions of dollars per annum. This immense business has been gained by years of persistent effort on the part of American manufacturers. Unless this agitation against Japanese residents in this country be checked promptly, we shall inevitably lose much of the ground that we have gained. The more enlightened among the citizens of the Pacific coast must exert earnest efforts not only in behalf of fair play, but also for the sake of American interests in a highly important place, namely the pocketbook.

ACCORDING TO THE New York SUN, the officers of the Amalgamated Copper Company asked the Government experts who went to Montana to investigate the smelter smoke nuisance if they could suggest a remedy. "The only thing they could offer was convert the poisonous products into sulphuric acid and build a pipe line to the Pacific Ocean, dumping the product into the sea." The Butte correspondent of the Sun says that this suggestion was made in sincerity; yet we feel that the Government experts must have been joking.

Mine Explosion in England

One hundred and thirty-seven miners were imprisoned Feb. 16 by an explosion in the West Stanley mine, at Durham, England. At present writing, all attempts to reach the men have been unsuccessful. The West Stanley shaft is 700 ft. deep, and is badly damaged. It is feared that the entombed men, if still alive, will perish before rescuers reach them. At practically the same time that the explosion occurred, a severe earthquake did much damage to property and lives on the northern frontier of Asiatic Turkey.

American Smelting and Refining Company

In its application for transferal to the regular list of the New York Stock Exchange this company made the following statements:

The American Smelting and Refining Company operates directly by itself and owns in fee the following smelting and refining works, all of which are equipped with the most modern machinery and appliances:

SMELTERS

At Denver, Colo.: The Grant Plant occupies about 120 acres of land within the city limits, but is not now being operated and has been virtually dismantled. The Globe Plant occupies 150 acres just outside the city limits. It has seven furnaces, with an annual smelting capacity of 322,000 tons.

At Pueblo, Colo.: The Pueblo Plant—100 acres, seven furnaces, 328,000 tons annual smelting capacity. The Eilers Plant—80 acres, six furnaces, 295,000 tons annual smelting capacity.

At Durango, Colo.: The Durango Plant—200 acres, four furnaces, 146,000 tons annual smelting capacity.

At Leadville, Colo.: The Arkansas Valley Plant—200 acres, 10 furnaces, 509,000 tons annual smelting capacity.

Near Salt Lake City, Utah: The Murray Plant—60 acres, eight furnaces, 523,000 tons annual smelting capacity.

Near Helena, Mont.: The East Helena Plant—250 acres, four furnaces, 235,000 tons annual smelting capacity.

At Monterey, Mexico: The Monterey Plant—300 acres, 10 furnaces, 460,000 tons annual smelting capacity.

At Aguascalientes, Mexico: The Aguascalientes Plant—300 acres, 10 furnaces, 720,000 tons annual smelting capacity.

At Chihuahua, Mexico: The Chihuahua Plant—200 acres, three furnaces, 153,000 tons annual smelting capacity.

At Chicago, Ill.: The National Plant—six acres, two furnaces, 60,000 tons annual smelting capacity.

At Maurer, N. J.: The Perth Amboy Plant—40 acres, three furnaces, 140,000 tons annual smelting capacity.

Making a total smelting capacity of 4,365,300 tons. The actual amount smelted has averaged about 3,500,000 tons annually. (This appears to include the capacity of El Paso and Omaha, stated below.)

REFINERIES

At Chicago, Ill.: The National Plant, with a capacity of 84,000 tons of refined lead and 16,400,000 oz. of refined silver and gold.

At Maurer, N. J.: The Perth Amboy Plant, with a capacity of 66,000 tons of refined lead, 66,000 tons of refined copper, and 36,000,000 oz. of refined silver and gold.

OTHER INTERESTS

The Consolidated Kansas City Smelting and Refining Company owns and directly operates a smelting plant near El Paso, Tex., known as the El Paso Plant—1500 acres, 10 furnaces, 492,000 tons annual smelting capacity. Every share of the capital stock of the Consolidated Kansas City Smelting and Refining Company is owned by the American Smelting and Refining Company.

The American Smelting and Refining Company operates a smelter and refinery at Omaha, Neb., known as the Omaha Plant, upon a leasehold running for 18 years from the present time. The smelting plant consists of two furnaces, with 82,000 tons annual smelting capacity. The refining plant has a capacity of 156,000 tons of refined lead and 36,000 oz. of refined silver and gold. The copper-converting plant has a capacity of 12,000 tons of blister copper annually.

The Omaha and Grant plants are subject to a mortgage issued by the Omaha & Grant Smelting Company, one of the original constituent companies making up the American Smelting and Refining Company. The bonds still unredeemed amount to \$349,000. By the condition of the mortgage they are still being redeemed yearly, and will be all redeemed in 1911. There are no mortgages other than the above on any of the plants or mines of the company, or of its constituent companies.

The annual value of the products of the smelters is approximately \$70,000,000.

The annual product of the refineries is as follows: Gold, 1,250,000 oz.; silver, 66,000,000 oz.; copper, 66,000 tons; lead, 225,000 tons; giving a total value of refined metals sold annually approximately \$97,000,000.

The company also owns and directly operates the following mines for the purpose of supplying ores which are most largely competitive:

At Sierra Mojada, in the State of Chihuahua, Mexico, the company operates five mines, with an annual output of 33,000 tons.

At Santa Enlalia, State of Chihuahua,

Mexico, four operating mines, with an annual output of 60,000 tons.

At Asientos, State of Aguascalientes, Mexico, one mine with an annual output of 72,000 tons.

The American Smelting and Refining Company guarantees the payment of quarterly dividends at the rate of 5 per cent. per annum on \$30,000,000 par value of the American Smelters' Securities Company preferred stock, series "B."

The investment account, in the statement of assets and liabilities, is made up very largely of 13,889 shares of preferred stock of the American Smelters' Securities Company, series "B," as well as 1600 shares of the preferred and 4500 shares of the common stock of the United States Zinc Company.

The company owns 177,510 shares of the common stock of the American Smelters' Securities Company, par value \$100 each, but as yet the value of this stock has not been included in the investments of the company.

Chihuahua Copper Company

SPECIAL CORRESPONDENCE

The property of the Chihuahua Copper Company, of which James Parker, of El Paso, Texas, is general manager, is situated 22 miles west of Moctezuma, Mexico, a station on the Mexican Central Railway, and 110 miles from El Paso. The hills in the vicinity reach an elevation of about 500 ft. A good wagon road leads to the property. The prevailing country rocks are limestones, andesites and quartz porphyries. The eruptives are massive, and well defined dikes are to be found from a few feet to several hundred feet in thickness. Large croppings of hematite and brown oxide of iron appear in the vicinity of the company's mines. Copper in various forms is found in these croppings and also disseminated throughout the bedding planes of the limestones. The mine shows native copper, malachite, azurite, chalcocite and chalcopyrite. Fluorspar is encountered in places. The chief development to date has been in the carbonate ores. Over 250 tons of ore has been shipped to the El Paso smelter, the copper content of which ranged from 6 to 9 per cent., with from two to three ounces silver per ton. The shaft is 230 ft. deep. Northwest of the shaft 200 ft. is a tunnel 100 ft. in length. This follows the bedding planes in the limestone and shows from one to three feet of good grade copper ore. Most of the ore shipped has been mined about 150 ft. from the tunnel, from irregular workings following the bedding planes in the limestone. About 2000 ft. northwest of these workings there is a large body of low-grade chalcopyrite. Here the ore seems to be thoroughly impregnate the fractured seams of the limestone.

Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Sampling by Machine

T. R. Woodbridge's classic diagram in the JOURNAL of Jan. 30 explains why the scoop of a sampling machine does not eliminate from 10 to 50 per cent. of the coarse particles from the sample at once, thus condemning the entire system without more ado. I can not speak for John A. Church, but my objections to the falling-stream principle are not quite so crude as that explanation seems to imply.

The theoretical division of the area is quite as it should be, that is, if the action of the machine were also according to theory. The explanation assumes that the lumps of ore which strike the edge of the scoop are regular in shape, that they slide gently upon it without impact and that they then invariably choose the side of the division toward which the center of mass inclines. It does not take into account the fact that the impact upon the hard-steel edge always causes more or less rebound, and that the chance of the flying particle's coming to rest in its proper receptacle is small, depending as it does largely upon the relative extent of the areas upon which it may fall. What is the area of the scoop as compared with that of the entire sampling room?

The rebound of the particles from the edges of the scoops is the great objection to sampling by slicing a stream of falling ore, and that is also the objection to the use of the assayer's scoop in the final division of the sample. In every one of the four positions of the scoop shown in Mr. Woodbridge's diagram, the edge interferes with the free fall of material, and the chances of the larger particles striking and rebounding are greater than those of the finer particles by the ratio between their respective diameters.

A simple experiment carried out as outlined below will prove whether my statement that it is possible to remove all coarse particles from a sample by repeatedly passing it over a sampler's scoop is correct or not. To make the process as little tedious as possible, prepare a sample by mixing clean dry screened quartz sand with a third to a quarter of its weight of $\frac{1}{4}$ -in. quartz lumps; 25 lb. will be enough. Take a single sampler's scoop, 2 in. wide between the edges and 2 in. deep. Remove the bottom and fix it upon a corresponding slit in the cover of a box. Now pour the sample upon the scoop with a shovel at any angle whatever. After all the material has been applied, there will be two

lots, the sample in the box which we may call "tails," and that upon the outside, which we may designate as "heads."

Repeat the operation upon the two lots separately, the tails yielding two products, tails and middlings, and the heads only heads and middlings. The middlings will be again separated into heads and tails. It would, of course, be still more effective if more classes of material were made, but three classes will usually tell the story before long. Continue the operation for, say, an hour, and then see whether a difference is not apparent.

I agree with Mr. Woodbridge's statement that, "sampling is a commercial enterprise calling for continual compromises between the theory of the subject and local requirements and conditions, and the allowable cost of plant and operation." Nor do I wish to condemn utterly the present sampling machine. It is simple and inexpensive and may be modified indefinitely with a minimum of ingenuity; moreover it answers the purpose very well except in unusual cases. It satisfies everybody but the captious ore shipper who is not a good gambler and refuses to take an even chance. It seems to me that that is saying a great deal for any mechanical device. Then why claim for it all the remaining virtues and deny that it has certain defects?

A. VAN ZWALUWENBURG.

New York, Feb. 4, 1909.

Successful Prospecting with Churn Drill Under Unfavorable Conditions

In the JOURNAL of August 1, 1908 in the article, "Steam Churn Drill in Hot and Cold Climates," J. P. Hutchins takes a pessimistic view of churn-drill prospecting when done under trying conditions. He used a steam-operated drill while under either class of conditions that he describes a gasoline-operated drill would have been better. In fact from Mr. Hutchins' article one would infer that if the weather is very hot, or very cold, or if the ground is very marshy, or water is very scarce, or if several other conditions occur in unison or singly, the power churn drill as a prospecting apparatus is very unsatisfactory.

This impression which he conveys, either intentionally or not, I desire to refute and to do so I am going to give a brief description of a type of churn drill, which we are successfully using, in pros-

pecting for coal in a country where there is little vegetation other than sagebrush, where the "wagon" roads are nothing more than sheep trails, where water is ten miles away and where moves from hole to hole often have to be made over every steep grade.

THE CHOICE OF THE TYPE OF DRILL

In churn drilling the important thing is to use a machine suited to the conditions under which the drilling is to be done, for it cannot be expected that one type of drill will be successful under all the conditions met with in drilling. When a man knows beforehand the conditions under which the work is to be done he should try to provide himself with a machine so constructed as to successfully meet those conditions. This at least was the idea followed out by the purchasers of our drill, and the success we have had with our drilling work seems to warrant me in recommending it to others.

If the holes to be drilled do not exceed 500 ft. in depth, it is folly to invest in a machine capable of drilling to a depth of 1000 ft. simply because some time in the distant future you might want to drill that deep a hole. Not only does a large machine cost a great deal more in the first place, but its weight is much greater, it takes more time and power to move it from hole to hole, and it takes more fuel to run it after it is set up. This item is not of such great importance when all conditions are favorable, but it increases in importance in direct ratio as conditions become adverse. If water and fuel are scarce and can be obtained only by long hauls, then steam as a motive power is not to be considered. If the country is rough and mountainous, with no roads and is sparsely settled, then a drilling method must be used which, without sacrificing speed in work or accuracy in results, will involve the least weight in outfit. If the work is to be done in a country where low temperatures prevail, then the outfit must be so arranged that nothing about it will freeze and interfere with the work. Contingencies such as I have mentioned and all such as have a bearing upon the work must be considered and planned for, in the purchasing of a drilling outfit, if the drill work is to be successful. As I have said before, and it is a point which cannot be emphasized too strongly, first find out the work which the drill will have to do and the conditions under which it will have to work, and then buy a drill to suit the conditions.

THE GASOLENE-OPERATED CHURN DRILL USED BY ROUNDUP COAL COMPANY

The drill work that I will describe is being done near Roundup, Mont., for the Roundup Coal Company. The machine is a little hollow-rod outfit, with a rated capacity of 500 ft., especially designed and constructed for meeting the adverse conditions such as prevail in this country. The power is furnished by a gasoline engine, the only kind which, owing to scarcity of water and the long hauls it would be necessary to make in order to get fuel, it is possible economically to use here. The engine is of special construction, being well adapted to the hard service of drill work and to undergoing the low temperatures which prevail at times. The drilling machine proper is mounted upon one set of trucks and the engine upon another set. This arrangement, while it necessitates a little more time in setting up, is especially adapted to haulage on steep grades, or over soft ground.

As gasoline power is continuous in its operation and admits of only a limited throttling, the drilling machine must be made so as to meet this condition. In the machine that we are using this difficulty has been overcome by placing a double clutch in the bull-wheel shaft, which, with the operating lever in one position throws the spudder in motion, and in the reverse position throws in the hoisting gear, but which, when it is on center, prevents the engine from gearing with either. The objection to the use of a clutch on the spudder has been overcome by making the clutch with an automatic positive attachment, which, however, does not engage until after the friction has taken hold, and then only when a heavy overload occurs; at such times the positive clutch engages and continues to hold until the clutch lever is thrown to the neutral position. This positive feature of the clutch is an arrangement which is highly recommendable in a clutch machine, when drilling in "heavy" ground. I mention these mechanical details simply to show that when special conditions are to be met special machines must be designed to meet them.

THE WORK ACCOMPLISHED

The holes being put down are 2½ in. in diameter, and at present range in depth from 100 to 300 ft. The Republic Coal Company, which is working coal lands near the Roundup company, has an exactly similar machine and has put down holes more than 650 ft. deep. I might add as a further evidence of the great usefulness here of the churn drill that the Republic Coal Company also owns a diamond-drill outfit which, owing to its high cost of operation in comparison with the churn drill, has been stored away, so that now all the prospect drilling is done with the churn drill.

The drilling done by the Roundup Coal Company is mostly in sandstone and shale,

with some limestone and slate. In an eight-hour day with the temperature 10 to 20 deg. F. below zero from 40 to 70 ft. is drilled. From 3 to 4 gal. of gasoline, and, in starting the hole, from 1 to 1½ bbl. of water are used per day. After a depth of about 100 ft. is reached the holes "bleed" a small amount of water and, as the rods pump it out as the water runs in, the hole supplies all the water that is necessary. Consequently, in drilling a hole it is often not necessary to haul more than 3 bbl. of water. This is an important item when the water often has to be hauled many miles over rough country.

Those who have spent a winter in Montana, or who have investigated its winter temperatures need not be told how cold it gets here, and yet this gasoline drill is able to operate satisfactorily in any weather in which it is possible for a man to work. From the satisfactory manner in which our little Cyclone machine has worked at the low temperatures here, I feel confident that it would prove equally satisfactory in any climate where man or beast can live.

If the churn drill is properly constructed mechanically and is adapted to the work it is expected to do, my experience has taught me that for certain kinds of prospect work, regardless of weather or other unfavorable conditions, churn drilling is one of the surest and cheapest methods of prospecting.

R. R. SANDERSON.

Roundup, Mont., Dec. 22, 1908.

"Concrete Lumber" and Forest Preservation

In a recent number of an engineering paper appears an editorial entitled, "How 'Concrete Lumber' Has Made Forest Preservation a Farce." The article opens with the following words:

"The fast-perishing forests of America have been the theme of many a statistical lament. 'Behold the loss of this wealth, this criminal waste of natural resources!' cries the statistician, until we find ourselves almost sniffling in sympathy. Amid all this *illogical agitation* (sic) for forest preservation it is well to turn an eye toward the timber of the future, 'concrete lumber,' as it has been aptly called. . . ."

Are we to understand that engineers and contractors are willing to look forward to a concrete age, which will be independent of the waste of natural resources? The statistician tells us that the production of cement in 1890 was 335,000 bbl.; in 1907 it was 52,000,000 bbl., worth \$56,000,000. Will someone tell us how many tons of coal will be required to manufacture the cement which the world will require during the present century? And then will someone go further and estimate how many board feet of lumber

are likely to be used to make the forms required for concrete construction? The organized effort which is now being made to educate the people, so that wasteful extravagance shall cease, should receive the hearty support of the engineering profession and press. The following statement of Dr. I. C. White, State Geologist of West Virginia, is likely to become classic and cannot be too often reprinted:

"Just as sure as the sun shines and the sum of two and two is four, unless this insane riot of destruction and waste of our fuel resources which has characterized the past century shall be speedily ended, our industrial power and supremacy will, after a meteor-like existence, revert before the close of the present century to those nations that conserve and prize at their proper value their priceless treasures of carbon."

ALLERTON S. CUSHMAN,
Assistant Director, Office of Public
Roads, U. S. Department of Agriculture.
Washington, D. C., Feb. 8, 1908.

Automatic Scale for Weighing Coal

The use of an automatic scale in weighing coal has heretofore been limited by the fact that no machine was designed to weigh coal unless the pieces were previously crushed to a diameter of less than 6 in. The Richardson Scale Company, of New York, has recently designed a machine which is capable of handling pieces of 15 in. and more in diameter. When this scale is used, the general practice is to first deliver the coal to a large bunker; this bin is then tapped on its sloping side to feed the automatic scale. When the exact quantity of coal has passed into the weighing hopper, the feed gate of the scale automatically closes and the hopper is discharged into a tapering spout, which carries the coal into the power house or other point of consumption.

This new scale is of 1500 lb. capacity, and is capable of handling about 100 tons per hour. The most unique feature of the machine is the method of feeding from a side gate rather than from an under-cut gate, as was employed in the former types. This new type of side-feed chute and gate entirely overcomes the difficulty of passing large lumps, and also the inability to raise the feed gate when it is closed, which were the chief troubles attending the use of the under-cut gate. It has also been found that only one-third as much power is required to raise the gate, as was necessary with the old type. The angle of the chute leading from the scale is about 40 deg. and the construction is such that it is impossible for the coal to bridge.

The deepest mine at Kalgoorlie, Western Australia (Percy Iould, *Aust. Min. Stand.*, Nov. 18, 1908), is the Great Boulder whose shaft is 2,400 ft. deep.

Electrically Driven Mine Pumps

By SYDNEY F. WALKER*

At mines, pumping was the first important work to which electricity was applied, and apparently the first electrically driven mine pump was installed at the Trafalgar colliery in the Forest of Dean, Gloucestershire, England. This pump was a small one using only about 1 h.p. In the United Kingdom, a great many collieries are worked through shafts, and a number of them are troubled with water. In slopes a self-contained, three-throw plunger pump, with an electric motor, mounted on a truck that travels along the ordinary slope track is a good arrangement for following the water down. A drum can be arranged that holds enough wire to allow the pump to be lowered a considerable distance; this way there is no change in the resistance of the conductors for a considerable time.

THE SERIES-WOUND MOTOR FOR MINE PUMPS

In the early days of the electrically driven mine pump, the series-wound motor was universally employed, partly because the shunt-wound motor was not then properly understood, and partly because alternating currents were not then used at mines. The method employed at that time in England, and I believe, very largely at the present day, was, and is, to run the pump for a certain number of hours during the day, lowering the water that had run into the workings sufficiently to allow work to be continued until the next pumping period. One of the difficulties was starting the pump. It usually had to be started against the resistance of the inert column of water in the pipes leading to the bottom of the shaft, and sometimes in the entire column up to the surface. Considerable torque was required at the moment of starting, and the series-wound motor furnished that quite easily. Unfortunately however, starting was only a part of the work that the motor was required to do, and starting against the inert column of water was only one of the conditions under which the pump was required to work. It was not unusual for the pump to be started and left to run by itself for a certain time, an attendant going to it occasionally, or it even being switched off at surface. This would have been all right if the quantity of water to be pumped had been the same day by day, but in a great many cases at least in Great Britain, especially at shallow mines, the quantity of water varies with the rainfall on the surface, the water making its way into the workings, not immediately after the rainfall, but at some later time depending

upon the overlying strata. This is the case of the series-wound motor led to trouble for, when the pump began to lose water, the series-wound motor would run away, and unless the current was promptly switched off, often injured itself, or the pump, but more particularly itself. This is one of the great defects of the series-wound motor. It changes its speed so much with a varying load. In coal cutting for instance, when a nodule of pyrites is met with, the series-wound motor will slow up and, providing there is power behind it, will cut its way through, but immediately the nodule is passed, it will commence to race unless the attendant is on the lookout, and is able to switch off the current, or stop it in other ways.

At the present time, there is apparatus on the market, that would enable the series-wound motor to be employed for pumping with perfect safety and without the necessity of constant attendance. Automatic appliances are arranged to start a motor when the level of the water rises to a certain point, and to stop it when the level has fallen to a certain point. The automatic appliance consists of a solenoid electro-magnet with a tripping contact, actuated either directly or indirectly by a float. The solenoid electro-magnet then actuates the ordinary starting resistance.

SHUNT-WOUND AND THREE-PHASE MOTORS FOR MINE PUMPS

The shunt-wound motor is undoubtedly the best all-round motor for general work about a mine, including pumping, and the three-phase motor is quite as good, except for the one objection that while the speed of the shunt-wound motor can be increased from one to six times, regulation of the speed of the three-phase motor is difficult. Both the shunt-wound continuous motor and the three-phase motor are self-governing, and both run at nearly constant speed—within about 4 per cent.

Where it can be arranged so that the pumping is done for a certain number of hours during the day, either the shunt-wound, continuous motor with continuous current, or the three-phase motor with alternating current will answer perfectly. They will deal easily with any variations of load incidental to the ordinary working of the pump. So long as the water that is made during a certain portion of the 24 hours can be pumped out so as to leave the workings free during working hours, the shunt motor, or the three-phase motor, running during those hours at constant speed, will do the work. Also with varying quantities of water, if varying times can be applied to getting the water out, again the shunt-wound and three-phase motor working at constant speed will do the work. But where large increases in the amount of water must be pumped at certain seasons of the year, after heavy rains, or due to other causes, and increased

time cannot be given to getting the water out, the pumps must be run at a higher speed.

The shunt-wound motor lends itself readily to increased speed. By adding a resistance to the field coils of the motor, which is thrown into the field circuit at the time that a higher speed is required, the speed may be increased as much as 20 per cent., and even in certain cases 25 per cent. But with the ordinary construction of the continuous-current motor, as the speed increases, and particularly as it approaches 20 to 25 per cent. above the rated speed, sparking commences and becomes somewhat violent at the brushes. This difficulty is easily overcome, if it is known, when the motor is ordered, that a varying speed will be required, for motors are now made with what are called commutating or auxiliary magnet poles, placed between the ordinary field magnet poles. These auxiliary poles suppress the sparking which takes place when the speed is greatly increased. There is not space here to explain the full action of the apparatus, but it may be mentioned that the increased sparking is due to the weakening of the magnetic field, produced by the insertion of the resistance in the circuit of the field coils. As the resistance added to the field coils is increased, the magnetic field produced by the field magnets is decreased, and the speed of the motor may be proportionately increased. By the aid of the commutating poles, the speed may be increased up to as much as six times the normal. Probably the ordinary motor, with resistance added, would answer the purpose, because the pump could hardly be allowed to run at more than 20 or 25 per cent. above its normal speed.

In the case of the three-phase motor, a similar method of regulation is not available because the speed of alternating-current motors depends, not upon the current strength, but upon the number of alternations of the current. A certain variation in speed can be obtained, say half speed, three-quarter speed, if it is known beforehand that it will be required, by altering the connections of the coils of the stationary part of the motor, but no intermediate speeds can be obtained, except by the use of wasteful resistances.

CENTRIFUGAL MINE PUMPS

It may perhaps be noted, that while the three-throw plunger pump has been such a great favorite, and such a good servant, the centrifugal pump now has many advocates. Not very long ago the centrifugal pump could only be employed for low heads, but now single centrifugal pumps are made for heads of 100 ft., and by placing two or more pumps in series, any head that may be desired can be worked against. I understand that the Worthington company has supplied centrifugal pumps raising water as high as

*Consulting engineer, Bloomfield Crescent, Bath, England.

2000 ft. in a single lift. The centrifugal pump is much more convenient than the three-throw plunger pump. It occupies less space for it can be connected directly to the axle of the driving motor, and the later designs of centrifugal pumps are certainly more efficient than the older forms of the three-throw pump. It also, however, has certain features that have to be reckoned with, when applying pumps. The centrifugal pump can be designed for constant quantity, constant speed, or constant head, but when the conditions for which it was designed are changed much, the efficiency of the pump decreases rapidly. Thus, in the case of the pump designed for constant quantity, its highest efficiency is when it is delivering that quantity. If the quantity is increased, the efficiency commences to fall, and with a comparatively small increase, falls very rapidly. On the other hand, if it is not delivering that quantity, its efficiency is also very much less. I have the results of a test of a pump designed to deliver 1250 gal. per min. against a head of from 100 to 117 ft., the pump to run at 700 r.p.m. At 700 r.p.m., the efficiency of this pump was about 72 per cent.; at 750 r.p.m., it was still 72 per cent.; at 800 r.p.m. it had fallen to 70 per cent.; at 900 r.p.m. it was only 58 per cent. and at 950 r.p.m. it was only 40 per cent. Similar conditions are met with in pumps designed for constant speed, or constant head. So long as centrifugal pumps are working within a short margin of the condition for which they are designed, they work at high efficiency, but when those conditions are departed from the efficiency falls very rapidly. These facts, it appears to me will bear upon the question of centrifugal pumps for mines.

The best form of pump would probably be that designed for constant speed, provided that the quantity of water to be dealt with did not vary much. In those cases where the water might vary, probably the pump designed for constant head would be the best. With constant speed, the pump may be driven by either the shunt-wound motor, or the three-phase motor, and should give at least as good results as the three-throw pump, but if the speed has to be altered, the shunt-wound motor is practically the only one available. With reference to the matter of the starting torque, in which the shunt-wound motor is comparatively weak, this difficulty may be overcome by having a few turns of wire on the motor, making it temporarily a compound-wound motor, the few turns being in series with the armature. These few turns will give the starting torque required and can be cut out after the pump is running at full speed. It should be mentioned, that the improved efficiency of the centrifugal pump has produced the natural result, improved efficiency in the three-throw pump.

The Utah Copper Company

The company's statement for the quarter ended Dec. 31 shows net earnings of \$530,658; rents, etc., \$9623; total net, \$540,281. The production of copper was 11,776,664 lb., or 224,261 lb. less than in the third quarter of 1908. The report says that 11 sections of the Garfield plant were in partial operation until Nov. 20, when the 12th and last section of the plant was placed in commission. Owing to the deficiencies in tonnage, largely due to transportation difficulties, but partially to unusually rigorous winter weather, the entire plant has not yet been operated to its full capacity, excepting for periods of a few days at a time. This deficiency is reflected almost in direct ratio in a decrease of copper output. The decrease in tonnage, and consequently in copper output, resulted in a proportionate increase in the cost per pound of copper; the average cost for the fourth quarter having been 9.35c., which includes all mining, milling, managerial, general expenses of all kinds, transportation, smelting and all selling costs. This result is readily understood when consideration is given to the fact that the tonnage we were unable to mill because it could not be supplied to the plants, could have been handled with practically no additional cost.

The recovery per ton of ore milled continues to be unfavorable, and very decidedly, influenced by the necessity of milling large quantities of oxidized and low-grade material resulting from the continued unavoidable admixture with the ores mined by steam shovels of a considerable percentage of such surface material, from which little recovery is made.

The earnings are based on an average price of copper for the quarter of slightly less than 14.10c. per lb., which is approximately the average price at which copper was sold during the quarter. The net price received for the last two months of the quarter was 14.30c. At the expiration of the quarter there was no finished copper on hand unsold—sales having been made during the quarter to cover all copper available for delivery up to about the middle of January.

Notwithstanding bad weather conditions, stripping of capping from the orebodies was continued, resulting in the removal of an average of slightly over 88,000 cu.yd. per month. Of the total ore mined and milled during the quarter 25 per cent. came from underground mining and 75 per cent. from steam-shovel operations; the increased percentage from shovels, as compared to last quarter, resulting in a further slight decrease in the cost of mining.

Since placing the last unit of the Garfield plant in commission we have been able to demonstrate, for short continuous periods, when we could secure the tonnage, that the plant has an economical operating

capacity in excess of 6000 tons per day, that being the nominal capacity for which it was designed. It has thus been determined that the two plants can handle more than 200,000 tons per month as soon as that quantity can be delivered to them.

Progress has been made toward the application to our operations of better and more secure transportation facilities, and we expect to be able to report definite measures for relief from existing difficulties in our next quarterly issue.

Events Following the United Mine Workers' Convention

The last of the coal miners' delegates and the district officers, who came from all parts of the country to attend the recent international convention at Indianapolis, have left that city. President T. L. Lewis has gone to Pennsylvania to open negotiations with the anthracite operators. The international board remained for several days to complete consideration of the things referred to it by the convention. The board discussed earnestly the situation in the anthracite district where the present scale expires April 1. It was decided to send committees into West Virginia and Pennsylvania to investigate troubles in those districts.

Just what will take place in the anthracite districts is a serious problem. Much is depending on President Lewis, and he is hopeful of getting the operators into a conference with a view of making and adopting a scale. The anthracite owners do not recognize the miners' organization except to permit them to hold their union meetings and to post notices in the mines regarding these meetings. The operators have for years refused to make contracts with the miners as a unionized organization. The mine workers do not believe a strike would be wise at this time, and will avoid such a thing if possible. The executive board will meet again in Indianapolis March 15.

Gold in Western Australia

Gold returns from Western Australia show a production of 139,160 oz. fine in December, which is 2160 oz. more than in November, but 15,295 oz. less than in December, 1907. For the full year ended Dec. 31 the report of the Council of Mineowners gives the total at 1,697,552 oz. in 1907, and 1,647,012 oz. in 1908; a decrease of 49,640 oz. The output of 1908 was \$34,062,341 in value.

The tin mines of Tasmania, according to a late report of the Secretary for Mines, employed during the last quarter of 1908 a total of 1747 men, 1641 of whom were Europeans and the balance Chinese.

Personals

Mining and metallurgical engineers are invited to keep **THE ENGINEERING AND MINING JOURNAL** informed of their movements and appointments.

John E. Rothwell, of Denver, Colo., has been seriously ill.

A. von der Ropp has been a visitor in New York, on his way to Europe.

Ernst F. Eurich, of New York, has gone on a trip to Panama and the West Indies.

Prof. Henry M. Howe, of Columbia University, New York, has returned from Europe.

Albert Maltman is superintendent of the Three Stars mine at Ophir, in Placer county, California.

James M. Barr has been appointed manager of the Woodstock Iron Company, at Anniston, Alabama.

Prof. J. W. Richards, of Lehigh University, South Bethlehem, Penn., has returned from his European trip.

Glenville A. Collins has opened an office for the practice of civil and mining engineering at Seattle, Washington.

C. W. Whitley, manager of the Utah smelters of the American Smelting and Refining Company has gone to San Francisco.

Doctor Heroult, of Paris, France, recently visited the Electro-Metals Smelter Works at Welland, Ont., in which he has an interest.

Sherwood Aldrich, president of the Ray Consolidated Copper Company, and D. C. Jackling, general manager, are at Kelvin, Arizona.

Neil McL. Curran, manager of the North Star mine at Kimberley, East Kootenay, B. C., has lately been in Montreal, on business.

Francis Henry Shepherd, of Nanaimo, Vancouver Island, B. C., has been appointed chief inspector of mines in the province of British Columbia.

Thomas Hoatson, managing director of the Keweenaw Copper Company in the Lake Superior district, is in New York, attending a meeting of the directors.

Archibald A. C. Dickson now has his office located at Rejoulie in the Gaya district, India. His telegraphic address is at Nawadah, on the East Indian railway.

J. M. Gray, who recently resigned the position of State mine inspector of Alabama, is now superintendent of the Empire Coal Company in Walker county in that State.

John B. Hobson, who for years has been engaged in hydraulic mining for gold in the Cariboo district of British Columbia, has been spending the winter in California.

Alexander Faulds, superintendent of the coal mines of the Nicola Valley Coal and

Coke Company, at Middlesboro, B. C., has resigned, and James Gray has been appointed in his stead.

James W. Malcolmson, mining expert for the Kansas City, Mexico & Orient Railroad Company, is in the City of Mexico. He is accompanied by L. M. Lamar, of Sabinas, Coahuila.

J. W. Carse, of the advisory committee of the Steel Corporation, has been in the Birmingham district in Alabama, inspecting the works of the Tennessee Coal, Iron and Railroad Company.

J. E. McAllister, general manager of the British Columbia Copper Company, attended the annual meeting of the company at New York, and returned to Greenwood, B. C., Feb. 10.

S. V. Tench, formerly superintendent of the Red Ash Coal Company at Wilkes-Barre, Penn., has been appointed superintendent of the Eastern division of the Lehigh Coal and Navigation Company.

Hon. Wm. Templeman, Canadian Minister of Mines, has been returned to Parliament as representative for the Comox-Atlin district in British Columbia, which enables him to retain his position in the Cabinet of the Dominion.

James Chynoweth, president of the recently organized Arizona & Michigan Mining Company, has returned to Calumet, Mich., after a visit to Globe, Arizona, where he has been inspecting the property of the new company.

Dr. F. H. Hatch, of London, well known for his work in the Transvaal, has been appointed mining expert for the colony of Natal. His first work will be the preparation of a report on the mineral resources of the colony.

George Gordon Crawford, president of the Tennessee Coal, Iron and Railroad Company, and Charles S. Stillman, Southern manager for Rogers, Brown & Co., have left Birmingham, Ala., for a trip to Europe and Egypt, which will last two months.

A. F. Holden, managing director, and the executive committee of the United States Smelting, Refining and Mining Company, have been at Salt Lake City. They are on a general trip of inspection to all the company's properties in the United States and Mexico.

H. L. Charles, formerly superintendent of F. Aug. Heinze's smelting plants in Utah and Montana, has taken a similar position with the Colusa Parrot Mining and Smelting Company, at Butte, Mont. This is a Clark property, generally known as the Butte Reduction Works.

Frank A. Keith, formerly general manager of the Tonopah Mining Company, Tonopah, Nev., has been engaged as directing engineer for the Pioneer Mining and Leasing Company. The position of superintendent of the Tonopah will be filled by W. H. Maddler, formerly with

the Devereaux Engineering Company of New York.

Obituary

Arthur G. Yates, who died in New York Feb. 9, aged 65 years, had been president of the Buffalo, Rochester & Pittsburg Railroad Company for several years. For many years he was a member of the firm of Bell, Lewis & Yates, of Buffalo, extensive coal operators in the western part of Pennsylvania. He was instrumental in organizing the Buffalo, Rochester & Pittsburg Coal and Iron Company, and was its president for several years before going to the railroad company.

Societies and Technical Schools

Royal School of Mines—The 36th annual dinner will be held at the Hotel Cecil, London, March 30. The secretary of the committee is George T. Holloway, 57 Chancery lane, London, W. C. In accordance with the usual custom of selecting a distinguished graduate to preside, the chairman this year will be F. W. Rudler, past president of the Geologists' Association. The secretary particularly requests old graduates to notify him of any change in their addresses.

Appalachian Engineering Association—At the fifth annual meeting at West Virginia University, Morgantown, W. Va., Feb. 6, the following officers were elected for the ensuing year: President, E. A. Schubert, Roanoke, Va.; vice-president, Baird Halberstadt, Pottsville, Penn.; secretary, Dr. Henry M. Payne, Morgantown, W. Va.; treasurer, C. E. Krebs, Kanawha Falls, W. Va. At the afternoon session the visiting members were welcomed by Dr. D. B. Purington, president of the university, to which President-elect Schubert responded in behalf of the association. After the auditing of the reports and the transaction of routine business the following papers were read and discussed: "Methods Used and Results Obtained in Triangulation of the Fairmont Region," by John G. Smyth, chief engineer of the Fairmont Coal Company; "Municipal Shortightedness," by Prof. D. C. Weller, Waynesboro, Penn.; "The Surveyor vs. The Engineer," by Guy B. Hartley, Morgantown, W. Va. The evening session was opened with a stereopticon address on "Machine Mining with the Electric Puncher," by John L. Wagner, Syracuse, N. Y., who was followed by E. A. Schubert, of Roanoke, Va., upon the subject, "Side Lights Upon the Iron Ore Deposits of the World, with Special Reference to the Virginias." Prof. R. L. Morris, of West Virginia University, then spoke on "Good Roads," and the session closed with an address by Dr. I. C. White, State geologist of West Virginia, on "The Barren Zone of the Northern Appalachian Coal Field."

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at
San Francisco, Goldfield, Salt Lake City, Denver, London and Paris

REVIEWS OF IMPORTANT EVENTS

San Francisco

Feb. 10—The Northern California Dredging Company is about to move its office from San Francisco to Eureka, Humboldt county. Thos. Blair is president and Frank H. Tooby is secretary, both of Arcata, and most of the stockholders are residents of Humboldt county. If the dredge now at Hamburg Bar comes up to expectations others will be put on the rivers in Humboldt county. The one at Hamburg is on the Klamath in Siskiyou county. The company has about 4000 acres of possible dredging ground in Humboldt county and it is probable that other dredges will be put in between Weitchpec and the mouth of the Klamath.

The Byron Jackson Machine Works are building at Berkeley the new machinery for a dredge to be put in use in the southern part of this State. It will be of large capacity and is being built for Los Angeles capitalists.

Since the renewed activity of the smelting companies in Shasta county more and more mining claims are being opened in that county. In the first two weeks of January of this year 150 claims were located, most of them for gold and silver, but some for chrome. These claims are in the districts of Shasta, Old Diggings, Centerville, Spring Creek, Lower Springs, Quartz Hill, Churntown, South Fork, Harrison Gulch, French Gulch, Pittsburg, Backbone, Texas Springs, Ono, Whiskeytown, Flat Creek, Muletown, Stella, Buckeye, and Slate Creek. Some of these claims were relocations, but many are new prospects.

The Weather Bureau is arranging to establish stations for reporting on the amount of snowfall in the mountains of California so as to determine how much water may be available from this source when the spring rains melt the snow. Some stations will be in the higher ranges for the purpose of getting snow measurements. This will be of great advantage to the miners of the State as well as to those raising crops. Two divisions are arranged for California. One division will be in the Sacramento valley and the other at Los Angeles, and a number of permanent observers will be employed at different points.

In northern Plumas county in the channel between the Sunnyside and Glazier mines, a distance of about four miles, a number of drift mines are being reopened and developed. These include the Sunnyside, Alum Cove, Last Chance, San Jose, Scott, Cameron and Glazier properties.

Work is also being done on the Pliocene and Salmon Falls claims which are continuations of the same channel on the north bank of the North Fork. There is apparent more activity also in the drift mining sections of Sierra county where some large enterprises are contemplated. Both Sierra and Plumas counties have vast tracts of ancient channel gravel not yet touched.

Goldfield, Nevada

Feb. 9—The milling output in Goldfield for the week ending Feb. 6 was from Goldfield Consolidated mill, 4200 tons valued at \$168,000; Florence mill, 630 tons valued at \$12,600; Nevada Goldfield Reduction Company's mill, 475 tons valued at \$37,750; Combination mill, 750 tons valued at \$30,000. This does not include ore shipped to the Western Ore Purchasing Company.

The output for Tonopah for the week ending Feb. 6 was Tonopah Mining Company, 3050 tons; Montana Tonopah, 745; MacNamara, 295; Tonopah Belmont, 650; Tonopah Midway, 50; Jim Butler, 300; West End, 250; total of 5340 tons having an estimated value of \$132,000.

The hole being drilled by the Bay State Oil Company at Salt Marsh, near Blair, is now 575 ft. deep; at that depth the drill is in blue clay heavily impregnated with oil. Several days ago it was reported that the drill had reached cap rock, but later developments proved the statement in error.

Coal has been reported to have been opened in paying quantities six miles north of Blair by H. C. Petty. The existence of this deposit has been known to Mr. Petty for the past five years, but little work was done. Three miners are now hoisting the coal from the 200-ft. level where a vein 24 ft. wide is disclosed; 42 in. of this is of a good coking grade.

After a litigation extending over a period of 15 years, Judge Pike recently rendered a decision in the district court at Reno, giving to the plaintiffs, B. A. Gamble, F. S. Chadbourne, et al. the power to enforce an option, to buy, dispose of or work the Pittsburg-Silver Peak mine from the time the judgment becomes final. The property in question is one of the large mines of the State and has been operated by the heirs of John I. Blair with a large output.

Charles S. Sprague, president of the Goldfield Chamber of Commerce, was

notified Feb. 1 that the American Mining Congress will hold its 1909 meeting at Goldfield. An attempt will also be made to have the meeting of the American Institute of Mining Engineers held here at the same time.

John Q. Critchlaw, president of the Chafey Investment Company, last week made the statement that his company had decided to install a 30-ton custom mill in the Chafey mining district; the intention is to enlarge the mill as conditions warrant.

Salt Lake City

Feb. 12—A blizzard of several days' duration has tied up the Utah Fuel Company's mines at Winter Quarters and Clear Creek, as well as those of the Union Pacific at Scofield. At Alta the snowfall has been greater than in many years. At Park City there has also been much snow. The Silver King Coalition is running out its regular tonnage; the Daly-Judge has kept its roads broken, and the Daly-West has been working through the Ontario tunnel. Most of the smaller properties, however, have been shut off by the snow and forced to discontinue work.

The storms throughout the State caused the smelters considerable annoyance. Some trouble is always experienced during the winter season, but this year it is far worse than usual. The American Smelting and Refining Company is operating five furnaces; three are idle. The United States Smelting, Refining and Mining Company has four in commission and three idle. The net earnings of the United States Smelting, Refining and Mining Company for November were \$398,000, for December about \$350,000, and for January probably in the neighborhood of \$300,000. The mines and plants of this company are said to be in excellent shape. President Sharp, Managing Director Holden and Messrs. Storrow, Winslow, Rice and Clark of the United States Smelting, Refining and Mining Company are here on a trip of inspection to the company's Western plants and properties.

E. P. Mathewson, who is in charge of the railroad and smelter construction for the International Smelting and Refining Company at Tooele, arrived here from Butte a few days ago. It is said that the company will soon let contracts for rails, structural steel and other equipment. The roadbed from the main line of the Salt

Lake railroad to the smelter site is now being built, and plans for the smelter are nearing completion.

A party of 25 Chicago capitalists under the guidance of W. C. Orem, made a trip of examination to the Boston Consolidated company's plants at Garfield. The Utah Apex mine, at Bingham, is shipping 90 tons of lead-silver ore and concentrates per day.

The shaft at the Black Jack mine, now 1,400 ft. deep, will be sunk to a depth of 2,000 ft. The Uncle Sam is drifting on the 210-ft. level and it is expected that the new orebody will be found within 200 ft. On the 100-ft. level they are also driving for this orebody.

The Sioux Consolidated has declared a dividend of 8c. per share, or \$59,631.12. This company has paid 33c. per share during the last five months. The Colorado company also posted a dividend of 8c. per share, or \$80,000.

The Utah Copper Company produced 4,174,859 lb. of copper in December, so that the production for 1908 amounted to 43,689,875 lb. The mill at Garfield consists of 12 sections of 500 tons capacity each. Two of these were placed in commission in July, 1907, and the remainder were started up as they were completed, the last unit being added in December, 1908. Since July, 1907, the production has been as follows: July-September, 1907, 5,305,368 lb.; October-December, 1907, 7,716,712; January-March, 1908, 8,527,939; April-June, 1908, 11,568,390; July-September, 1908, 12,000,925; October-December, 1908, 11,592,621 lb. During this time the shares have been selling at \$13 to \$52. As soon as the price of copper improves the mill will probably be enlarged. At present the company is said to be clearing a little over 5c. on each pound of copper produced.

The drain tunnel on the 1200-ft. level of the Daly-Judge mine is being driven toward Bonanza Flat, paralleling the Daly fissure. The Daly company extracted \$9,000,000 worth of ore along a distance of 1500 ft. on this fissure. The Daly-Judge company is now able to handle the water on its 1,400- and 1500-ft. levels. This will give to the company an immense area of stope ground, that up to date could not be worked owing to the large quantities of water coming from the Daly fissure.

Denver

Feb. 13.—The United States Reduction and Refining Company, in its annual report, shows that the company's operations from Aug. 1, 1907, to Jan. 1, 1909, gave a net profit of \$372,876, of which \$225,250 was paid in interest on bonds, and \$50,187 paid in preferred dividends, leaving a balance of \$88,439 to be put in the treasury.

The two chief owners and organizers of

the Western Metals Company, owning the electrochemical ore-reduction process, are about to show that they have the courage of their convictions, by erecting a plant at two mines, one in Georgetown, and one in Idaho Springs, of which mines they are respectively one the owner and the other the general manager.

It is also announced that a custom cyanide mill of 150 tons capacity, for the treatment of low-grade telluride ores, is to be built at Sugar Loaf in Boulder county.

Toronto

Feb. 12.—On Feb. 11 the Judicial Committee of the British Privy Council rendered its decision in the case of the Dominion Iron and Steel Company vs. the Dominion Coal Company for breach of contract, sustaining the judgment of the Supreme Court of Nova Scotia in favor of the steel company and remitting the case to that court to have the damages assessed. This is probably the most important Canadian civil action on record. For a time the coal company was leased and operated by the steel company. This arrangement ceased in 1903, and on Oct. 20 of that year an agreement was entered into under which the coal company agreed to furnish the steel company with all the coal required for 90 years at \$1.24 per ton, with 4c. per ton for use of cars. The steel company, in accordance with the terms of the agreement indicating that the coal was to be taken from the Phelan seam of the Dominion coal areas, as most suitable for its purposes. In the year 1905, the coal company made default as regards furnishing a sufficient supply. The steel company in April, 1906, notified it that during August, September and October it would require 80,000 tons per month. The coal company only supplied 58,270, 50,525 and 62,618 tons for these months, respectively. The steel company offered to take slack and banked coal without prejudice to contract rights to make up the quantity, but on the coal company's failing to deliver, it was notified that the steel company would not take coal except from the Phelan seam. After Nov. 1, 1906, the coal company's cars were sent to the steel works labeled, "Run-of-Mine Phelan Seam," without indicating the pit from which the coal was taken, thereby compelling the steel company's analyst to analyze the coal to ascertain its quality with the result that much of it was rejected as unfit for steel manufacturing.

The coal company thereupon gave notice that the contract was terminated on the ground that it had been broken by the rejection of the coal. The steel company closed its works Nov. 6, 1906, until it could arrange for securing coal elsewhere, and a temporary agreement was made for a supply from the coal company at a price much higher than that

specified in the original contract. The steel company sued for damages and, after a trial lasting 16 days, Judge Longley, of Nova Scotia, found in its favor. The coal company took an appeal to the Privy Council.

Lord Atkinson, in an elaborate judgment declared that it was not a case into which it was necessary to import by implication words into the contract to effectuate the intention of the parties. The contention of the coal company that the phrase, "reasonably free from stone and shale," appearing in the contract implied that the coal supplied should be only as free as reasonable and proper picking could make it, apart from impurities in the laminae permeating the coal, could not be sustained. The provisions of the contract were only explicable on the assumption that of the coal to be supplied, 90 per cent. was to be reasonably suitable for use in the operations it was known the company intended to carry on in the works described. The plaintiffs were entitled, owing to the wrongful repudiation of the contract by the defendants, to treat the contract itself as at an end, and recover damages in respect to breaches of it committed before its repudiation, viz., to Oct. 31, 1906. The coal company was ordered to pay the costs of the appeal.

About \$57,000,000 of capital are affected by the decision, the stock and bond issues of the Dominion Iron and Steel Company amounting to about \$34,000,000 and those of the Dominion Coal Company to \$23,000,000.

Victoria, B. C.

Feb. 8.—The Dominion Government is making provision for a representative display of the minerals of British Columbia, as well as of the products of other parts of Canada, at the Alaska-Yukon-Pacific Exposition to be opened at Seattle, Wash., next summer. R. W. Brock, director of the Geological Survey of Canada, has requested that the district boards of trade collect the minerals for the exhibit, he has intimated that a Dominion official with wide experience in connection with mineral exhibitions will be detailed to look after the final selection and display. It is suggested that mineral specimens shall be 1 cu.ft. in size, with a few very large specimens of high-grade silver-lead and copper-gold ore; also specimens illustrative of the metallurgical processes and products, building stones, clays and clay products, and in fact all natural economic substances.

The matter has been taken up energetically by the Associated Boards of Trade, which at their recent annual convention appointed a committee to make arrangements for a representative exhibit from the Kootenay and Boundary districts. As yet, though, there has not been similar

practical interest shown in the Coast district of the Province, and the Provincial Government has not announced any intention to promote the object in view in making a large exhibit, leaving arrangements to the Dominion Government as being more within the jurisdiction of the latter.

William Hutchinson, Canadian exhibition commissioner, accompanied by an architect from Ottawa, was in Seattle early in February, making preliminary arrangements for the Canadian building at the exposition, for which structure an appropriation of \$75,000 has been made.

At the seventh annual convention of District No. 18 of the United Mine Workers of America, held recently at Lethbridge, Alberta, an important departure was made in connection with Asiatic labor. Heretofore, in the constitution under which the affairs of the district were carried on, an invitation was extended to all men employed in and around mines, without regard to race or color, excepting Chinese and Japanese, to unite with the organization. The constitution committee advised the striking out of the words "except Chinese and Japanese," and after a spirited debate this was agreed to by a majority of those in attendance at the convention.

At Edmonton, Alberta, in the district court, a judgment was lately given, by Judge H. C. Taylor, which is of importance to laboring men employed in that province. This was in the matter of an action brought by 18 employees of the United Collieries Company against two directors of that company for the recovery of wages due, amounting to about \$760. The action was regarded as a test case and the judgment shows that wage-earners may recover the wages due to them by the company from any or all of the directors of a joint stock company, in the event of the company failing to pay.

London

Feb. 2—The West African goldfield continues to interest speculators and there is a considerable traffic in shares. The popularity that the goldfield is now enjoying is founded more on anticipation of future prosperity than on successful results already achieved. For on the whole, mining on the Gold Coast has, in the past, been a disappointing business. It is claimed, however, that improved results have lately been obtained by the crushing mines and further improvements are promised if capital is provided to enable operations to be carried on on a larger scale.

Whether these optimistic views, upon which the present boom appears largely to be founded, will be realized, remains to be seen. The recent records of the prominent mines indicate that dividends are still a considerable way off. In the report

of the Fanti Consolidated Mines, Ltd., for the year ended Sept. 30, 1908, it is stated that at the Presta Block A mine, one of the best quartz mines of the colony, the costs for August, September and October last were \$5.52 per ton milled exclusive of development. Allowing 96c. for development, which was the amount allowed in 1907, and 40c. for London expenditure, the total working costs come to \$6.88. During these three months the value of the gold recovered was about \$7.44, so that the margin of profit is very small. At the Abbontiakoon Block 1 mine, one of the basket group, the costs for August, September and October were \$7.80, exclusive of depreciation, and the revenue \$8.74 per ton.

At the Wassau mine, another basket mine, the yield for the year, 1908 works out at \$6.72 per ton milled. The costs during 1907 were \$8.64, and during January, February and March \$4.80 exclusive of development and London expenditure, which may be put at \$2.40, making a total cost of \$7.20. There is no profit here. The Abosso and Taquah mines, both on the basket field, show more favorable results.

The Taquah commenced crushing in September, 1907, with a new 50-stamp mill. For the period to June, 1908, the yield was \$16.32, and the costs \$10.56. For the year 1908 the yield has been \$16.56 per ton. At the Abosso mine the yield and costs for the year ending June, 1907, were \$14.44, and \$9.12, respectively, and for the year ending June, 1908, the yield and costs were \$12 and \$8.40. During the last six months of 1908 the yield has fallen to \$10.80 per ton milled. The reduction in grade that the mines develop with increased production is very noticeable.

In the face of the above figures it is difficult to get up much enthusiasm about West African gold mines; and it is somewhat surprising that fresh money is being found by one or two of the South African mining houses to develop some of the dormant properties floated during the last boom.

Until the old established mines have been placed on a sound dividend-paying basis, it seems premature and incautious to attack areas of the basket field, where the indications of value are less favorable, as far as is known at present, than in the present working mines.

Paris

Feb. 3—T. Moreux, manager of the Observatory of Bourges has recently advanced an explanation of firedamp explosions. He finds that these explosions are in close relation with the tempests of the sun and consequently with the spots that are observed frequently on the surface, and that earthquakes also take place during the same periods. In fact, in No-

ember last two enormous spots were observed on the sun causing magnetic deviations on Nov. 12, the date of the disastrous explosion at Hamm, Westphalia. On April 29, 1896, violent earthquakes accompanied by storms were observed at the time of the disaster in the Giphy mine and the explosion at Micklefield. On July 3, 1898, earthquakes and storms in Italy and Austria accompanied explosions of fire-damp in Belgium in a mine where that gas had never been detected before. Among many other dates given by T. Moreux is that of the Courrières disaster in March, 1906, which occurred during a period of solar crisis.

The French mining law of 1810 has been frequently discussed in the Chambers with a view of altering it, but so far no fundamental modification has been adopted. A new mining law will be submitted soon to a vote of the deputies. The commission which is preparing it has decided to adopt the principle of the nationalization of the mines, i. e., to cause the mines to be worked by the State, or at least to make an investigation with that end in view. A sub-commission will examine conditions in Switzerland and Holland where mines are operated in this manner. The proposal of the commission will be submitted to the Chamber of Deputies before spring.

Portable electric lamps are now used underground at the Bruay and Carvin collieries. They weigh a little less than 5 lb., last 12 hours, have a capacity of 1.2 candlepower under two volts, consuming two watts per candlepower. The accumulator alone weighs 2½ pounds.

The largest producers of gold in Madagascar, Mortages & Grignon, are erecting a complete 950-lb. 25-stamp mill at their mine of Andavakoera in the northern part of the island 100 kilometers from Diego-Suarez. Owing to the difficulties of transportation the machinery supplied by Fraser & Chalmers, Ltd., was sectionalized to 500 kg. It is reported that it safely reached the mine and the erection is well advanced. The mill will probably be started in March. The Governor of Madagascar intends to attend personally the starting of this mill, which will be the first stamp mill running in the colony. Up to the present time the Andavakoera ore has been picked by about 3000 natives, crushed by hand in small mortars and then washed in *bateas*. A native crushes about 12 lb. of ore per day. As the natives chose only the pieces showing visible gold, considerable ore is on hand for the mill besides the ore not yet extracted by the natives. Assays made on ore carrying invisible gold show 100 gram per metric ton. The ore of Andavakoera has been worked by the owners for 17 months, and the average monthly production has been 100 kg. gold containing about 25 per cent. silver. The richness of the ore is increasing for the production of a single fortnight recently was 180 kg. of gold.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

ARIZONA

COCHISE COUNTY

Bisbee—The Phelps-Dodge copper smelting companies have filed with the Interstate Commerce Commission, at Washington, complaints against the Baltimore & Ohio and other railroads, alleging discrimination in the rates for transportation of coke from Eastern cokefields to smelters in Texas and Arizona. The complaints say that the railroads charge 30c. a ton more from the coking region to Chicago on coke used for smelting copper, than on coke used for smelting iron. Practically all the coke used by the Southwestern smelters is shipped by way of Chicago and complaint is lodged only against the charge made for the haul to that point, the rate beyond being satisfactory.

GILA COUNTY

Arizona Commercial—At a depth of 710 ft. in the Eureka shaft, a station 36 ft. square is being cut.

California

AMADOR COUNTY

Boardman Hill—Joseph Garibaldi has commenced hydraulic mining the gulch on the Boardman Hill, the last spot which has never been mined in the Volcanic Basin. The top dirt only is washed. The claim is in dispute before the Land Office, but Garibaldi is so sure of winning the contest that he has begun work.

BUTTE COUNTY

Big Blue Lead—Test washes of gravel show \$3 per car in coarse gold, the fine gold not being saved.

CALAVERAS COUNTY

Benson—A 15-ft. vein of satisfactory quartz has been found in this mine at Altaville; George F. Walker, superintendent.

Bovee-Fritz—This is a reorganization of the company owning the Sultana mine near Angels. Capital has been secured, and active operations will shortly commence.

EL DORADO COUNTY

Golden Hatchet—Garretson, McLellan & Co. are about to secure the gravel mine on Webber creek, 10 miles from Placerville. The mine is on one of the well defined gravel channels of the county.

INYO COUNTY

Dodd's Springs—Jas. L. Butler is opening a new mine under the superintendency of John McCormack in the Saline Valley section at Dodd's Springs. The ledge carries gold, silver, copper and lead.

KERN COUNTY

Tungsten—The tungsten mines at Atolia have started up again with about 60 men at work.

Yellow Aster—The company at Randsburg is now employing 300 men and taking out large quantities of ore. Mining is quite active at Randsburg and Johannesburg.

MODOC COUNTY

Fort Bidwell Consolidated—From the Mountain View claim, R. L. Mason, superintendent, some high-grade ore is now being taken at a depth of 70 ft.; ore is being taken out from this and other mines in Hoag district to be ready for the 20-stamp mill to be erected this spring.

NEVADA COUNTY

Lecompton—This Nevada City mine, Samuel Colt, superintendent, has been compelled to close down owing to water due to the heavy storms. Work will not be resumed until winter is past.

Niagara—At a meeting of the company at Grass Valley it was decided to move the offices to Santa Barbara. It is possible that the mine may be reopened after the rainy season is over.

Yellow Metal—A 12-in. ledge at this property near Bowman's dam is yielding high-grade ore. The mine is being developed by A. D. Keller for Nevada City and Grass Valley men. The mine is in the granite gold belt, in a new district.

PLACER COUNTY

Northern California Gold Mining Company—W. R. Leonard and A. F. Sawhill, of Pittsburg, Penn., are examining the Herman mine and the financial standing of the company in Placer county.

Three Stars—The work of pumping out has commenced under superintendence of Albert Maltman.

SAN BERNARDINO COUNTY

In the district 10 miles north of Bagdad and Amboy, several companies are developing orebodies. One company has a mill and others in the district are working on the same ledge.

SIERRA COUNTY

No Better—At this group, owned by the Forest Green Gold Mining Company at Forest, J. C. Chandler, superintendent, the shaft is now down 165 ft., and will be continued to 500 ft., when drifts will be run.

SISKIYOU COUNTY

Bennett & Co.—This firm now has five big hydraulic plants at work near Forks of Salmon with plenty of water for effective work.

Dakin—This copper mine at Happy Camp continues working, and, having moved the power house, now has plenty of power.

Gardner & Weed—On this claim in Quartz Valley 15 men are at work with several giants, and have plenty of water for hydraulic mining.

Grouse Creek Gravel—This company near Callahan, has a full head of water for all its giants. This is an ideal season for hydraulic mining.

TRINITY COUNTY

East Fork District—On the Yellow Jacket a small force of men has been set at work in the tunnel to develop the orebody found last fall. Development work is also being done on the Meier, Weedman & Condon, Johnson, Oversight group and Golden Chest. The Hoodoo is being developed by Grant Day near the Enterprise, with George S. Fenwick as superintendent.

TUOLUMNE COUNTY

Nonpareil—Arbuckle & Morrison have commenced work on this claim under a bond given them by the assignees of the creditors. The property is expected soon to become a producer.

Soulsby—This mine at Soulsbyville has resumed operations with a full force of men after running some time with only one shift.

Colorado

LAKE COUNTY—LEADVILLE

Bertha—In this mine, Breece hill, the body of ore opened in the lower level has widened out to a fair oreshoot; the ore running well in gold. It is more than likely if a satisfactory extension of the lease is granted to the present lessees, that they will sink the shaft to a depth of 500 ft. to open the orebody at greater depth.

Dinero Tunnel—In this adit, Sugar Loaf, the upraise, that is being carried from the tunnel level to make connections with the old workings, recently ran into a body of high-grade silver ore. In about three weeks the upraise will have made the connection and developing the body of ore at the breast of the tunnel will be started. Shipments will be started as soon as the wagon road is opened to the smelter.

Iron Silver—This company is increasing its force of men on the Moyers, Iron hill, and also the Tucson, and the daily output is materially increased. As long as spelter remains at its present figure the company will gradually increase the working force and its output. The same can be said of the A. Y. & Minnie.

Jennie June—In this mine, Tennessee Pass district, drifting from the bottom of the shaft to the north on the vein has been going on during the winter, following a small streak of ore that carried gold. The vein is now widening.

Sunday Tunnel—The footwall of the recent strike has been caught and the vein from wall to wall is 12 ft. wide, with 6 ft. of solid mineral; the balance is milling ore. The ore is a lead sulphide carrying 60 per cent. lead, with gold and silver. At present the tunnel is being driven ahead and when sufficient ground is cut for a large station and compressors, etc., installed, the work of connecting with the shaft will be started and also drifting on the vein, both sides.

TELLER COUNTY—CRIPPLE CREEK

El Paso Consolidated—The annual report of this company shows that the property produced during the past year ore to the amount of \$432,000, or 19,600 tons of the value of about \$23 per ton. In January, 1908, the property was leased to a number of operators who have taken out the ore. No ground below the water level, or 600-ft., was leased. No work was done on company account. Good headway is being made on the drainage tunnel. El Paso will be one of the first mines to be unwatered. A. L. Burris, of Colorado Springs, is the president of the company.

Gold Issue—The surveys from the railroad to the mill of this company have been completed and it is understood that the construction work will soon commence. The mill, which is known as the Wish Bone mill, is situated on the north side of Mineral hill, away from the railroad, and the surveys that have just been made are for the purpose of running a line from Hoosier pass, so that ore can be taken from all parts of the district to the mill. The mill owners have leases on several mines and dumps in the district. P. M. Collins, of Cripple Creek, is in charge of the mill. Some new machinery is being installed.

Golden Cycle—Ground is being broken

for a new mill on this property, designed to treat the very low-grade ore at the mine and in the dumps that will not stand the freight to the valley mill of the company. It is understood that the mill is to be a concentrator and is to have a capacity of 500 tons per day. A large amount of ore is produced by this property. H. McGarry, of Colorado Springs, is general manager.

Trail Mountain—Some prospecting is being done on this hill, which is some distance south of the town of Victor. Several years ago a mill was erected in this vicinity and some ore treated. The mill is not running at present, but some values are reported as having been found in prospecting. As this is outside the known mineral belt, developments are being watched with interest.

Illinois

MERCER COUNTY

Coal Valley Mining Company—This company's mine at Cable has been finally worked out and abandoned after 35 years' continuous operation. The mine was worked on the room-and-pillar system, and all the pillars were successfully taken out, except those immediately around the bottom of the shaft. The company will soon begin work on another shaft, three miles from the old one. It will be equipped with the latest machinery.

Indiana

WARRICK COUNTY

White & Wilson Coal Mining Company—This company's shaft on the Lutz farm west of Boonville, has reached coal. The vein is 6 ft. thick and of excellent quality. It is 60 ft. below the surface and has a good roof of limestone rock. A switch is being put in from the Southern railway. The company will begin operations in the fall, with a daily capacity of 1800 tons.

Michigan

COPPER

Seneca—The shaft being sunk at this property has reached the first level, a distance of 200 ft. from the surface. A crosscut is being driven to the lode from this point. The shaft is in the footwall approximately 60 ft. from the lode.

Ojibway—The lode has been encountered in cutting the station at the 650-ft. level of No. 1 shaft. The face of the formation is well charged with copper. The lode opened in the level above consisted of two beds separated by about 14 ft. of trap.

New Baltic—This exploration company operating on lands adjoining the Arcadian property has opened up the lode and disclosed an amygdaloid formation. The

ledge is covered with but a few inches of overburden and is badly disintegrated, but it is believed to be an extension of the Baltic lode.

Wyandot—This company continues driving the crosscut from the bottom of its exploratory shaft, a distance of 700 ft. from the surface, and is now cutting the third amygdaloid formation. Drifting northward on the first formation continues and the same minerals, epidote with some copper. No. 2 lode is being opened to the south and is about the same as the first formation.

Osceola—This company has stopped stamping Ahmeek rock in its mills, which in all probability means an increased production from its own shafts. No. 4 shaft of the North Kearsarge branch will soon be in condition to begin producing.

Alloes—The Kearsarge lode recently encountered in No. 2 shaft of this company is proving up exceptionally good.

Columet & Hecla—This company has put in commission a series of electrically driven centrifugal pumps in No. 5 shaft, which will take care of all the water from the northern portions of the mine, and has discontinued water hoisting at the Red Jacket shaft.

Montana

BUTTE DISTRICT

Butte & Balaklava—The shaft is down 1248 ft. and ore has been encountered at that depth. Sinking has been temporarily stopped and a station is being cut on the 1200-ft. level from which a crosscut will be run. Sinking will then be continued to the 1500-ft. mark. The management states that a modern surface plant will be installed and orders have already been placed for the machinery. The last 110 ft. of the three-compartment shaft were sunk and timbered, and all rock hoisted to the surface during a period of 30 days, which is a record for the camp at that depth.

Butte-Montana—A plan for reorganization is under consideration by which the capital will be increased to \$2,000,000, with shares of the par value of \$10. Ten of the old shares are to be exchanged for one of the new and a portion of the new stock will be sold for the purpose of carrying on further development work. Development work is now being carried on in the lower levels and shipments are averaging two railway cars per week.

Raven—Operations were suspended Feb. 8 by order of the board of directors. It is understood that the stockholders have failed to support the directors' efforts to refinance the company by subscribing for the treasury stock recently offered to them, and the directors, being unwilling to advance more money for continued operations, have shut down the mine. The time in which the stockholders may sub-

scribe for the new stock has been extended to Feb. 24, and if no response is forthcoming by that time the property may be closed permanently. The mine was formerly worked through the Buffalo shaft of the Amalgamated company, which was leased for that purpose to the Raven company, but since a dispute arose as to the ownership of several bodies of ore opened up through the Buffalo, the further use of the shaft was refused and the company then began to sink on its old shaft and reached a depth of 1300 ft. before the suspension of operations.

DEER LODGE COUNTY

Washoe Smelter—The new 87-ft. blast furnace was blown in last week and is the largest in operation in the world. The two other blast furnaces are 51 ft. in length. There are eight reverberatory furnaces at the plant. The smelter is producing from 300 to 400 tons of copper daily, depending upon the grade of ores smelted.

JEFFERSON COUNTY

Elkhorn Electrometals Company—The new electrolytic plant was put in operation on Feb. 5. The plant is the first commercial one of its kind in the country.

BROADWATER COUNTY

Keating Gold Mining Company—Final payment was made last week upon the company's group of claims in the Radersburg district. The management has under consideration a plan to use traction engines in place of teams for hauling ore.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Blue Bull—In the Knickerbocker lease on this property, ore of good grade has been cut in a drift from the bottom of a winze sunk from the tunnel level.

C. O. D. Consolidated—The oreshoot that was cut in the drift from the winze sunk from the 200-ft. level has also been cut by the crosscut run for that purpose on the 300-ft. level. The orebody has been penetrated for about 4 ft., and shows high-grade shipping ore the entire distance, with considerable free gold showing.

Combination Fraction—The first shipment to the Nevada Goldfield Reduction Company's mill under the new terms was made Feb. 1. The shipment consists of 105 tons with an average value of \$40 per ton. A daily production of 85 tons will be maintained in the future. Forty additional men were put to work at the mill which is now in position to run, at full capacity, 20 stamps.

Crackerjack—The shaft on the Mitchell & Fairfield lease on the Henry Clay lode of the Crackerjack company is now 135 ft. deep. The low-grade vein that was

cut at a depth of 95 ft. still shows in the bottom of the shaft.

Goldfield Whiterock—This company is doing a large amount of exploratory work. From shaft No. 7 a crosscut is being run to the east on the 540-ft. level to connect with shafts Nos. 4 and 5, about 2000 and 2200 ft. distant, respectively, through ground never before opened up.

Great Bend Diadem Lease—A rich strike was reported in the west drift on the 400-ft. level of this property last week; 20 in. of this ore is very rich.

Hazel Lease—At a meeting of the stockholders of the Hazel Goldfield Mining Company recently held in Chicago, W. H. Jordan was elected president, F. Fitch vice-president and treasurer, and A. R. Cuthbert secretary. John A. Farwell and Geo. H. Phillips are the additional directors. The mine is making about 20,000 gal. of water per day, and a pump is to be installed. The shaft will then be sunk an additional 150 ft., and development work carried on to the east of the shaft.

Little Florence Lease—A double-drum, electric hoist, and a compressor capable of supplying nine drills, are being installed. Development work has been curtailed owing to the inefficiency of the gasoline hoist now in operation; with the new hoist in operation both hoisting compartments of the shaft will be used. The crosscut on the 357-ft. level recently cut the hanging wall of a promising looking vein, but where cut it is low in gold. The crosscut has passed through 14 ft. of vein matter without reaching the footwall.

Red Top Consolidated—A dividend of 2c. per share, amounting to \$20,000 was declared Feb. 1, affecting stockholders of record Feb. 20. Ore is being mined at four different points in the mine; all the ore is of high grade.

ESMERALDA COUNTY—HORNSILVER

Great Western—The west drift on the 300-ft. level recently opened a large body of good gold-silver ore. This ore is considerably richer than that in the same shoot on the 200-ft. level. The property is shipping an average of one carload a week to the Western Ore Purchasing Company.

ESMERALDA COUNTY—LUNING

Blue Light Copper Company—The shaft, now more than 700 ft. deep, is being sunk deeper; the intention is to continue it to water level. The property has produced some ore, and considerable ore is now blocked out.

Parrot—Work on this property has been resumed by the Nevada Champion company. Much money has been spent in opening this mine, but all work was stopped with the decline of copper.

NYE COUNTY—BULLFROG

Bullfrog Pioneer—This property shipped two cars aggregating 80 tons last week, having an estimated value of \$100 per ton. The crosscut is not yet in the lode proper, though it is thought that the footwall has been cut. A number of new leases have been granted on Pioneer ground adjoining the Bi-Metallic claim, the leaseholds being blocks 200x300 feet.

Gold Hill Mining and Milling Company—This company, operating on the Conservative claim which adjoins the Pioneer Bonanza lease, is planning to sink a two-compartment shaft to a depth of 50 ft. A hoist has been ordered.

Homestake-King—It is estimated that the clean-up for January will show a production of about \$13,000. The mill is now treating about 75 tons per day averaging \$7 per ton.

Montgomery-Shoshone—The mill treated 4600 tons of ore during the month of January. The last shipment of bullion weighed 800 lb., and included the product of the concentrates which are now being treated successfully at the mill.

National Bank—The Logland lease on this property is preparing a shipment for the smelter at Needles; the shipment will be about 30 tons and all comes from the 50-ft. level.

NYE COUNTY—HELENA

Broken Hills—This company is at present sinking two shafts; the main working shaft is about 220 ft. deep. In the drift on the 100-ft. level from this shaft a body of milling ore 25 ft. wide has been opened up. This shaft will be sunk to a depth of 300 ft. before another crosscut is run. Much the richest ore on the property was opened up in an incline shaft about 200 ft. from the main shaft; this high-grade vein was followed from surface to a depth of 90 ft. The vertical shaft, which was sunk from the surface to connect with the bottom of the incline, is now 60 ft. below the bottom of the incline shaft, and has been in ore below the incline. A drift being run on this body from the 45-ft. level found an orebody of shipping grade 12 ft. wide. Twenty blocks of ground have been let to leasers; all of these leases are being worked, and many of them are equipped with up-to-date machinery. A good grade of ore has already been opened up on two of the leases. The town of Helena, which has sprung up since the mine was opened, now has a population of about 300 people. The Broken Hills company is constructing a telephone line to connect the camp with Tonopah, 12 miles of the line being already in operation. This work will be completed in about three weeks. J. C. McCormack, principal owner and manager of the property, states that the Broken Hills ore is a petzite carrying about two-thirds of the value in gold. The survey

has been made for the mill site, but more exhaustive tests of the ore will be made before the plans for the mill are drawn. The company owns water rights ample for all milling and domestic purposes.

NYE COUNTY—TONOPAH

Montana-Tonopah—The mill ran continuously with all the stamps dropping and crushed 1040 tons of ore, 745 of which came from this property and 295 tons from the MacNamara. The contract in force under which the company agreed to treat an average of 50 tons per day from the MacNamara expires March 15 and will not be renewed.

NYE COUNTY—IONE

Ione—Thomas D. Murphy, E. R. Collins and Downie D. Muir, all of Goldfield, are preparing for extensive work on their placer ground, which comprises about 500 acres. A Fairbanks-Morse pump and 10,000 ft. of pipe have been ordered. Ione is south of the Reese River range, from which a large water supply can be easily obtained.

WHITE PINE COUNTY—ELY

Steptoe Smelter—During the month of January, 2,700,000 lb. of blister copper were shipped. The smelter is now treating nearly 5000 tons of ore per day of which two-thirds comes from the Nevada Consolidated and the balance from the Cumberland-Ely companies.

New Mexico

GRANT COUNTY—SYLVANITE

Sylvanite Townsite and Development Company—William Clark has purchased a controlling interest in the Sylvanite Townsite and Development Company. John T. Goshen, who has been the agent of the townsite company since its organization, has resigned as secretary, and C. H. Morse, president of the Eureka Sylvanite Mining Company, has accepted the position as secretary and agent under the new management.

Gold Hill Mine—I. J. Russell, the superintendent, reports 6 ft. of shipping ore in the upper tunnel; the two lower tunnels are both in good ore. A compressor plant is on the way to the mine. Ore bins have been built. Regular shipments were commenced this week.

Sylvanite Queen Mining Company—This company, which owns the Ajax, Alexander, Cowboy and other promising claims in the Eureka district, has elected new officers. Asa T. Hoy is president; E. A. Tovera, vice-president; G. K. Reynolds, secretary, and J. P. Connelly, treasurer, all of Bisbee, Arizona.

Fairview Group—This group of four claims at Granite Gap, four miles south-east of Sylvanite, has been optioned to G. F. Humbert. At this property there is a dike, 40 ft. wide, that carries copper, gold and silver.

Pennsylvania

BITUMINOUS COAL

D. G. La France & Co., of Johnstown, has bought from various owners a tract of 2830 acres of coal land in Quemahoning township, Somerset county, the price paid being \$225 per acre. The coal on the land is the lower and middle Kitanning and the Freeport seams.

FAYETTE COUNTY

Republic Connellsville Coke Company—Plans are in progress for the organization of this \$2,500,000 corporation which has been formed by merging the Republic Coke Company and the River Coal Company.

South Dakota

LAWRENCE COUNTY

Hidden Treasure—Work is to be resumed in the early spring when Supt. Nate Hart, of Lead, will commence drifting on the 200-ft. level to tap the ledge struck in the shaft.

Pennsylvania—Drifting on the 150-ft. level is being prosecuted, and it is expected to strike the vein within a few feet.

Pluma—President T. A. Harding, who spent some days here, announced that the plans for building a 500-ton mill would be completed soon. Work will commence in the spring when the drifting will be continued.

PENNINGTON COUNTY

Deep Down—A new strike has been made in a drit on the 50-ft. level where a body of free-milling gold ore was opened up. It also carries bismuth, and is being developed.

Dakota Power—Work is about to be resumed by L. A. Richards, of Rapid City, who has just returned from an Eastern trip, having completed financial arrangements to finish the flume work and establish and equip a generating plant.

Utah

BEAVER COUNTY

Beaver Carbonate—The new compressor at this mine has been started. Development work in the large orebody on the 700-ft. will now be hastened.

Commonwealth—Two drifts are being driven on the 400-ft. level; both show considerable ore.

Harrington - Hickory—This property owned by the Majestic Mining Company has opened a shoot of fine lead-silver ore on the 500-ft. level, just above water level. The entire face of the drift is in ore.

Peacock Consolidated—Three fissures are being prospected by drifts. In one of these, ore carrying gold, copper and silver has been found, and in another 2½ ft. of good lead-silver ore shows.

DAVIS COUNTY

Buckland Mining Company—This company has been incorporated for \$100,000, the shares having a par value of 10c. The company will develop 14 claims in the Farmington mining district.

TOOELE COUNTY

Shipments—During the week ending Feb. 5, the Tintic mines have shipped as follows: Dragon Iron, 29 small cars; Colorado, 62; Ajax, 4; Brooklyn, 7; Beck Tunnel, 4; Swansea, 6; Black Jack, 2; Horn Silver, 4 small cars. The Centennial Eureka mine shipped 44 large cars; Eureka Hill, 8; Gemini, 2; Yankee, 2; May Day, 2; Eagle & Blue Bell, 1; Bullion Beck, 2; Sioux Consolidated, 14; Iron Blossom, 3; Ajax, 1 large car.

JUAB COUNTY

Bullock—At this property good copper-silver ore has been cut in the shaft at a depth of 190 feet.

Eureka Lilly—The shaft is being re-timbered to the 300-ft. level. As soon as this work is completed drifting will commence.

Tintic Standard—A crosscut is being driven on the 400-ft. level, but it will be some time before the vein is reached.

SALT LAKE COUNTY

Big Milt—A shaft is being sunk on the vein. Some of the ore assays several thousand dollars in gold and as high as 26 per cent. copper.

SUMMIT COUNTY

Shipments—The Park City mines shipped as follows for the week ending Feb. 5: Silver King, 1,951,480 lb.; Daly-West, 1,150,000; Daly-Judge, 683,000; Daly-Judge, zinc, 800,000 lb., or a total of 4,584,480 lb. The smelter settlements for the week ending Feb. 6 were \$675,000.

Woodman—This group consisting of six claims has been added to the property of the Ohana Mining Company. On the Woodman there is a good showing of gold-silver-copper ore; the company also owns water rights. The Ohana company will run a tunnel 700 ft. long, to cut three veins which have promising surface showings.

Wyoming

CARBON COUNTY

Penn-Wyoming Copper Company—The properties of this company, which has been operating mines, mills and a railroad at Encampment, are reported sold to a new \$10,000,000 corporation, the United Smelters, Railway and Copper Company.

Canada

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ending Feb. 6 were as follows: Buffalo, 44,260 lb.; Coniagas,

126,500; Crown Reserve, 272,540; Kerr Lake, 81,637; La Rose, 310,620; McKinley-Darragh, 41,000; Nipissing, 255,310; O'Brien, 64,040; Temiskaming, 120,000; Trethewey, 125,400; total, 1,441,397 pounds.

City of Cobalt—In the course of sinking a winze from the 200-ft. to the 300-ft. level a rich strike was made at a depth of 225 ft. from the surface, the vein having a width of 9 in. of high-grade ore. Native silver slabs and argentite were found.

Crown Reserve—A strike has been made in the north crosscut at the 100-ft. level, consisting of two veins, each about 3 in. wide, and 15 in. apart. One of the veins gives an assay of 12,000 oz. of silver to the ton and the other more than 2000 ounces.

La Rose—On the McDonald vein at the tunnel level the width has increased from 2 to 6 in., the ore still showing high silver contents and yielding in places over 10,000 oz. to the ton. In No. 10 tunnel stoping is in progress. The shaft on No. 3 vein is being continued from 125 to 150 ft. or deeper. On Feb. 10 the Imperial Privy Council gave judgment in the appeal case in the suit of the La Rose Mining Company against the Temiskaming & Northern Ontario Railway Commission. The La Rose, owning property on each side of the track, claimed the right to mine under the railway. The Canadian court decided against them and this decision was confirmed by the Privy Council and the appeal dismissed.

McKinley-Darragh—The big concentrator with a capacity of upward of 60 tons per day is now in operation. The winze by which the 200-ft. level is reached will be sunk an additional 100 ft. At the bottom of the winze is from 3 to 4 in. of high-grade ore. On the Savage property No. 2 shaft is down 112 ft. The financial statement presented at the annual meeting showed receipts from sales of ore during the year, \$345,792. The expenditures included additions to plant, \$46,231; operation and development, \$139,921, and dividend, \$202,309. The amount of cash on hand at the end of 1908 was \$46,612.

Peterson Lake—On the leasehold of the Kerry Mining Company, ore showing good silver contents has been found at 95 ft. in the main shaft. A vein 2 to 4 in. wide, which had previously shown niccolite, has run to cobalt with native silver.

Station Grounds Mining Company—This company is negotiating contracts with the Cobalt Lake Company to prospect its holding from the working of the Cobalt Lake. The west drift of the latter company is under the lake for several hundred feet at a depth of 154 ft. and is now within 50 ft. of the Station Grounds boundary.

ONTARIO-GOWGANDA DISTRICT

Bonsall Claims—These claims, comprising 320 acres, the first to be staked and developed in the region, have been purchased by Hon. Clifford Sifton and M. J. O'Brien for \$500,000. Several veins of native silver have been found.

ONTARIO—LARDER LAKE

Dr. Reddick—At the annual meeting held at Ottawa Feb. 1 the shareholders rejected a proposition to amalgamate with the Cleopatra mine and the Richardson claim of the Larder Lake district. It was decided instead to issue \$500,000 more of 8-per cent. cumulative preference stock, bringing the capital up to \$2,500,000—only \$300,000 of the amount to be issued at present. The report of the superintendent showed that the first 30 tons melted yielded \$8 and the next 100 tons between \$10 and \$12 per ton.

Mexico

CHIHUAHUA

Barranca de Cobre—Mendoza and Nesbitt, leasing operators of this mine and mill in the Urique section, are making regular shipments of high-grade copper-gold ores and concentrates to the Aguascalientes plant of the American Smelting and Refining Company.

Cerro de Tarahumares—Promising lead-silver properties are being exploited in this section 30 miles west of Conchos on the Mexican Central. Among the operators are Leon Escobar and Luis Terrezas, Jr., of Chihuahua.

Guazapares—Since the opening up of the Rio Plata silver mine there has been prosecuted successful prospecting at a number of localities tributary to this old camp. One of the best prospects is that opened up by L. S. Ferry and W. E. Orr.

Zinc Ores—Following the recent affirmative decision of the United States Court of Appeals in placing carbonates in the calamine class as duty-free in importation to the United States, there is evidenced a greatly increased demand for Chihuahua zinc ores. Large United States concerns have lately had representatives in the field and the closing of several large contracts with producers in the St. Eulalia, Los Lamentos and other districts is reported. A number of zinc mines and prospects have also been optioned to responsible men and the indications point to an early and marked improvement in the State's zinc industry.

Hidalgo—This Boston company is now preparing for the equipment and operation of its property situated 80 miles north of Parral. J. V. Dignowity is managing director, and E. L. Dignowity is the superintendent.

GUANAJUATO

Production—Shipments of concentrates for the week ending Feb. 8 to the smelter at Aguascalientes amounted in value to

\$90,500. During the same period \$175,000 in bullion was shipped to the refinery at Mexico City.

JALISCO

Chatterton Mining Company—The mines of this company in the Tapala district have been sold to W. H. Baldwin, of Delavan, Ill. The Virginia and the San Antonio are the principal mines of the group. There is a 10-stamp mill and concentrating plant.

SONORA

Black Mountain—The new oil-burning machinery for the power house at Magdalena has arrived and will probably be installed ready for operation about the middle of February.

Douglas Copper Company—The company smelter at Fundicion and the mines at El Cobre, which have been idle for several months, are expected to be in operation about the middle of February, according to the resident manager.

Quintera Mining Company—The mill has shut down and some of the old material is being disposed of. The management is reticent as to the cause of the shutdown, but refuses to dispose of any of its new material or stock supplies. The company is controlled and managed by a French syndicate.

San Antonio de La Huerta—The San Antonio Copper Company was organized under Arizona laws last October as a holding company for the San Antonio Copper Company, S. A., of Mexico, which owned this property in Sonora. The holding company has 250,000 shares of stock, par value \$10. of which 100,000 have been issued as full paid, 100,000 shares issued upon which \$1 per share has been paid in and 50,000 shares remain in the treasury. The board of directors of the company comprises John Uno Sebenius, director of the North Butte Mining Company; L. W. Powell, vice-president of the Calumet & Arizona Copper Company; E. G. Kingsford, of Michigan; C. D. Fraser, of New York, and D. G. Kerr, of Pittsburg. Otto C. Davidson is president, J. A. Crowell vice-president and George J. Eisele secretary and treasurer, all of Iron Mountain, Mich. The property is 80 miles from a railroad, but the Cananea, Yaqui River & Pacific railroad should be built to the property by January 1, next. The property is in the early stages of development, but the work to date has disclosed high-grade ore.

Zambona Development Company—The Zambona, at Minas Nuevas, is preparing to resume active operations and will install a new 200-ton plant for fine grinding and cyaniding. This equipment will consist of tube mills, Pachuca agitators, vacuum filters, classifying machinery, pumps, etc. A. J. Yeager is the general manager.

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, Feb. 17—The bituminous coal trade in the East continues quiet, no activity having developed since our last report. Manufacturers seem to be using only a moderate amount of coal, and are very reluctant to replenish their stocks.

The anthracite trade continues dull. The decrease in January shipments as compared with last year is apparently a forerunner of other losses to come. The anthracite companies, as a rule, are not running their mines full time. Most of them are operating only three or four days in a week. Even at that, coal is still being stocked in anticipation of the strike or suspension of mining which everyone now believes is sure to come in the spring, when the present agreement will expire. It is understood that President Lewis of the United Mine Workers has notified the anthracite companies of his readiness to discuss with them the question in dispute. No answer has been made, however, and it is quite probable that the companies will refuse to take up the question with anyone outside of their own employees.

In the West there is a little improvement in trade here and there, but no general advance. Steam coal continues dull and the mild weather still restricts the domestic demand. The recent storms brought some cold weather with them, but it did not last long enough to have any permanent effect on the trade.

The committee appointed by the Pittsburgh coal operators has had one hearing before the Interstate Commerce Commission but the matter was adjourned in order to give the railroads time to present facts. The claim made by the Pittsburgh people is that the present rates on coal to Lake Erie ports constitute an unlawful discrimination against the Pittsburgh district and in favor of West Virginia and Ohio coals. The Ohio people—particularly those in District No. 8 and the Hocking Valley—while willing to admit discrimination in favor of West Virginia, maintain that their rates are unequal also. They think that the Pittsburgh people desire an unfair advantage

COAL TRAFFIC NOTES

The coal production of Colorado in 1908 is reported as follows: Anthracite, 69,440 tons; bituminous, 6,824,117; semi-bituminous, 818,216; lignite, 1,901,234; unclassified and small mines, 70,000; total, 9,773,007 short tons.

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to Feb. 8, 1908, and Feb. 6, 1909, in short tons:

	1908.	1909.	Changes.
Anthracite.....	546,046	492,720	D. 53,326
Bituminous.....	3,275,860	3,490,394	I. 214,534
Coke.....	725,922	1,016,582	I. 290,660
Total.....	4,547,948	5,005,696	I. 457,748

Average daily tonnage, 116,614 in 1908, and 135,289 in 1909; increase, 18,675 tons.

Shipments of coal passing Lock No. 4 on the Monongahela river for the year were 8,336,620 short tons in 1907, and 6,095,880 in 1908; a decrease of 2,240,740 tons, or 26.9 per cent.

Coal receipts at Boston in January reported by Chamber of Commerce:

	1908.	1909.	Changes.
Anthracite.....	141,579	99,855	D. 41,724
Bituminous.....	244,016	226,444	D. 17,572
Total domestic.....	385,595	326,299	D. 59,296
Foreign.....	45,702	28,200	D. 17,502
Total.....	431,297	354,499	D. 76,798

The foreign coal comes chiefly from Nova Scotia mines.

Coal and coke tonnage, Chesapeake & Ohio railway, six months ended Dec. 31, short tons:

	Coal.	Coke.	Total.
New River.....	3,288,078	108,855	3,396,933
Kanawha.....	2,688,150	15,205	2,653,355
Kentucky.....	160,860	—	160,860
Connecting lines.....	129,315	35,929	164,644
Total.....	6,236,403	159,389	6,395,792
Total, 1907.....	6,050,553	221,134	6,271,687

Deliveries in 1908 to points west of mines, 3,290,177 tons coal and 96,184 coke; points east, 774,049 tons coal and 63,205 coke; tidewater, 2,164,639 tons coal; anthracite to line points, 4538 tons.

New York

ANTHRACITE

Feb. 17—The anthracite trade locally is in the same quiet condition that it has been in for some time past. It is still a weather market, and the weather has not been such as to stimulate the demand for coal. Many collieries are running short time and this has resulted in a rather smaller supply of the steam sizes. There is enough, however, of these sizes to meet current demand. Domestic sizes are still being stocked on a large scale.

Prices are unchanged. The list prices for prepared sizes are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points.

BITUMINOUS

The discussion of yearly contracts is still in order. It is held back for the time by the fact that the railroads have not yet announced the rates for the coming season. It is generally believed, however, that there will be no change from last year and a few contracts have been made. Producers are not willing to make any concessions from the low prices of last year, and it is quite possible that contract prices may be a shade higher.

As far as current business is concerned the Far East is taking no coal. Business is dead and dealers are wondering how consumers have made their stocks hold out. The Sound ports are buying some coal, but not in a large way. New York harbor is a bargain counter and business depends on the small necessities of the buyer. Good grades of steam coal are selling at \$2.40@2.50 f.o.b. harbor shipping port, while lower grades can be had at \$2.20@2.30. All-rail trade seems to be better than tide-water and more coal is being taken. Car supply is abundant and transportation is fair, coal coming through on about schedule time.

The Coastwise market is slow and vessels are hunting for charters. The rates still continue pegged at 75c. from Philadelphia to around Cape Cod. The quoted rates for large vessels from Philadelphia are: Boston, Salem and Portland, 75c.; Lynn and Bath, 85c.; Newburyport, 95c.; Portsmouth, 80c.; Providence, New Bedford and the Sound, 65@70c. per ton.

Birmingham

Feb. 15—The coal trade in Alabama is quiet, and there is a curtailment of production. Never before has there been such a slack demand during the winter as at present. Chief State Mine Inspector Edward Flynn states that the production is off at the present as compared to the latter part of 1908, and that conditions are approaching those that prevailed a year ago.

There is no need for such a large production of coke, and as a consequence some of the ovens are to be cut off while others have been cooled off already. There is a large quantity of coke already stacked up.

Chicago

Feb. 15—Cold weather in the last week has increased the demand for both bi-

tuminous and anthracite, and has bolstered up prices that were inclining downward because of the previous unseasonable weather. This situation is encouraging for the immediate future, but affects domestic coals more than steam and is looked upon by the trade as likely to be of brief duration. The real improvement that is looked for is a general increase in the demand for steam coal and there are no signs as yet that such a change is at hand. Eastern as well as Western coals have been benefitted by weather conditions, though there is still a condition of general overloading of the market by eastern coals.

Illinois and Indiana lump brings \$1.80 @ 2.40, run-of-mine \$1.60 @ 1.75 and screenings \$1.40 @ 1.60. Smokeless, the leading coal from east of Indiana, continues in such large supply that sacrifice prices are made to escape demurrage, the list being cut 15¢ @ 25¢, making Pocahontas and New River lump \$3.05 @ 3.45, and run-of-mine, \$2.85 @ 3.15. Hocking Valley likewise has been in too large supply, but is now holding up nearer to the list price of \$3.15 than for many weeks, though some has sold at \$2.75 in the last week. Youghiogheny moves almost wholly on contracts at \$3.15 for 34-in. gas and Pittsburgh No. 8 is slow at \$2.05 @ 2.75.

The anthracite market has notably improved in the last three or four days, but individual sales are small, though widely distributed.

Cleveland

Feb. 16.—The cold snap has cheered up the retailers, and consumption of domestic coals has improved, but hardly enough to call for any change in prices. In steam coals there is no alteration in conditions. Slack continues to sell better than lump or run-of-mine. There is much interest here in the movement to adjust rates on coal for Lake shipment.

Indianapolis

Feb. 15.—E. L. Wolford, president of the United Fourth Vein Mining Company, has closed a contract with the United States Steel Corporation for from 7500 to 15,000 tons of Fourth Vein coal a day. The Fourth Vein company owns seven mines in the Linton district. Part of these have been idle for several months and others have only been kept in operation as the business permitted. The new contract, with the other business that will be handled, is expected to improve working conditions in this field very materially.

The United Mine Workers have finally adjourned, the most interesting point left unsettled being the anthracite situation, which is now in the hands of President Lewis and the special committee. The

executive board will hold a meeting March 15, in Indianapolis.

Pittsburg

Feb. 16.—During the week the Crucible Steel Company of America sent out inquiries for its supply of coal for the year beginning April 1. It usually takes 200,000 tons and the Pittsburg Coal Company has held the contract for several years. They will be strong competition for the business, as annual contracts this year are rare. Consumers who heretofore made contracts in January for the year are buying only as they need the coal. When asked to renew old contracts they say they do not know whether they will need any coal this summer. The mines are running about the same as last week, the river mines being in full operation and the railroad mines running about 35 per cent. The Pittsburg-Buffalo company is doing better than other concerns as its production is around 70 per cent. The Marianna mine, where the great disaster occurred in December, is in full operation. The rivers reached a coal-boat stage this morning and so far about 2,000,000 bu. of coal have gone down to lower ports. More coal likely will be sent out tomorrow. Prices remain unchanged and are on the basis of \$1.15 a ton for mine-run coal at the mine. Slack is selling at 65¢ at mine.

Connellsville Coke—Outside of the placing of a few contracts for furnace coke the week was a dull one. Several small orders were received for foundry coke at reduced prices. Most of the producers are holding furnace coke for prompt shipment firmly at \$1.75 and on contract at \$1.90 @ 2. Some sales were made at about 15¢ a ton less. Foundry coke has declined and \$2 @ 2.15 is quoted for both spot and for deliveries running to July 1. The *Courier* gives the production in both fields at 262,156 tons. The shipments amounted to 9674 cars as follows: To Pittsburg district, 3488; to points west of Pittsburg, 5306; to points east of Connellsville, 880 cars.

Foreign Coal Trade

German Coal Trade—Imports and exports of fuel in Germany, year ended Dec. 31, metric tons:

Imports:	1907.	1908.	Changes.
Coal.....	13,721,509	11,661,503	D. 2,060,006
Brown coal.....	8,963,103	8,881,966	D. 81,137
Total coal.....	22,684,612	20,543,469	D. 2,141,143
Coke.....	584,221	575,924	D. 8,297
Briquets.....	195,404	192,391	D. 3,013
Exports:			
Coal.....	20,061,400	21,062,362	I. 1,000,962
Brown coal.....	22,065	27,877	I. 6,812
Total coal.....	20,083,465	21,090,239	I. 1,006,774
Coke.....	3,704,073	3,879,278	D. 213,795
Briquets.....	1,301,661	1,493,104	I. 191,443

Coal exports exceeded imports in 1908 by 846,770 tons; coke exports were in ex-

cess by 3,003,354; and briquets by 1,300,713 tons.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on Feb. 6: Best Welsh steam, \$3.42; seconds, \$3.24; thirds, \$3.12; dry coals, \$3.48; best Monmouthshire, \$3.06; seconds, \$2.94; best small steam, \$2.16; seconds, \$1.92. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, Feb. 17.—The iron and steel trades continue to be in a waiting condition. The combined effect of the expected changes in the tariff and the general belief in a coming reduction of prices have kept the markets extremely quiet, in almost all lines. While the tariff discussion has its effect, the price question is really the leading influence at the present time. Cutting is reported in almost every kind of finished material. No open action has been taken by the leading interest, but there is no doubt that some step in this direction is under serious consideration. A significant point is that a contract with the Steel Corporation for plates which has existed for some years on the part of a large steel-car manufacturer has expired, and has not been renewed, the company preferring to buy in the open market.

In pig iron, business is very dull, few new orders coming in. Northern furnaces are nominally maintaining prices, but there is no difficulty in securing concessions on a good order. The foundries are buying only for immediate needs and no placing of contracts is reported. The only melters who seem to be at all well supplied with orders are the cast-iron pipe makers, most of whom have a good deal of work on hand. In the South, furnaces are claiming that the price of \$13 base for No. 2 foundry at Birmingham is maintained, but it is currently reported that business has been taken at 25 and 50c. less.

In finished material there is nothing doing except in structural material and plates. The structural people are taking some contracts and there are a number of building projects ready to be put in hand, but the question of prices is holding purchasers back. The railroads have placed some orders for steel cars which will require a considerable tonnage of plates and shapes. Otherwise there is little railroad business coming forward and rail orders are at a minimum point.

An informal meeting and dinner of steel-trade representatives was held in New York, Feb. 17. No official statement was given out, and it is said that no positive action was taken, though there was a general discussion of the price question. The general belief is that a decision involving a general "readjustment" of prices may be expected at an early date. This will undoubtedly have a favorable effect on the trade.

Baltimore

Feb. 16—Exports for the week included 209,687 lb. tin scrap to Rotterdam; 2,025,542 lb. steel bars, 775,711 lb. galvanized sheets and 158,328 lb. tinplates to Panama. Imports included 1118 tons ferromanganese from Liverpool and 10,800 tons iron ore from Cuba.

Birmingham

Feb. 15—Southern pig-iron manufacturers are confident that there will be an improvement in general conditions before long. There has been no curtailment in the production yet. If inquiries which are coming in develop any business, there will be a demand for all the iron that can be manufactured. The orders which are being received now are in small lots. There has been no change made in quotations and the general price is \$13 per ton, No. 2 foundry. The make in this district is better than it has been for a year and a half. It is believed that production during this month will show an increase over January, though during that month there was more than 148,000 tons of iron reported. The home consumption is holding up well, the cast-iron pipe plants working practically full, the machine shops and foundries doing well and the steel plant of the Tennessee company doing fairly well.

The announcements of the reorganization of the Southern Steel Company and the statement that there will be a resumption of operations in the near future at several of the plants of this company, has had an encouraging effect.

Chicago

Feb. 15—The iron market continues very quiet. Sales of pig iron are in small lots. Everywhere melters seem inclined to go slowly and await developments—tariff legislation and the inauguration of a new President. Prices are weakening generally, though a collapse is apparently not looked for by buyers; even at lower prices, openly quoted, it is probable, to judge from the tone of opinion in the local trade, that buying would not be much larger. Carload lots up to 300 or 400 tons, with an occasional lot for more as the exceptional purchase, will apparently continue in vogue for the next week.

Quotations are not stable, remaining nominally at \$13 Birmingham (\$17.35 Chicago) for Southern No. 2 and \$17.50 for Northern No. 2. Cuts of 25 to 50c. under these figures evidently prevail and a large sale might bring still lower prices. That there is a sagging tendency in Southern cannot be denied, but it is asserted in some quarters that Northern will remain fairly stable because of diminished output of the local furnaces.

Iron and steel materials are in general dull, though structural steel is in better

demand. Coke is weak at \$4.85 for the best Connellsville.

Cleveland

Feb. 16—No buying of iron ore is reported. The furnaces seem to be in no hurry to take ore, and sellers are not pressing. No action has been taken on prices for the coming season, but the general belief is that no change will be made.

Some inquiries for pig iron have been received, but no considerable sales are noted. The tendency is to shade prices where a fair order can be secured. No. 2 Northern foundry is quoted nominally at \$16.25@16.50, Cleveland, but sales are reported at 50c. less.

Finished material is dull, with the exception of some inquiries for structural steel.

Philadelphia

Feb. 17—No progress can be seen in pig iron. Foundry business is in small lots, and little is doing in basic. Some inquiries for this sort are in, but they have not produced results so far. While some furnaces are holding back and standing on their prices, others are hungry for business and are quite willing to make concessions to get it. Buyers are not in any hurry, apparently, and do not seem to think they will lose anything by waiting.

Steel Billets—Business has been disappointing, only a few small sales having been made, at unchanged prices.

Bars—The store demand is reported about the same as last month. The market is not in good shape, and iron bars have been offered at low prices; steel bars are also cut.

Plates—Some demand from car-builders has kept up this market, but prices are uncertain.

Sheets—No change is reported, and business is on a small scale.

Pipes and Tubes—Local business is only moderate, though a little more demand from boiler shops is noted.

Structural Material—New building contracts are talked about, but most of them seem to be held back on the price question. If that is settled right, there will be good business placed.

Scrap—Some dealers are quietly laying in stock, believing there will be a demand for it before long. Others, however, are letting things drift, and are afraid they will have to carry stock too long to make it profitable.

Pittsburg

Feb. 16—Efforts to maintain prices in all lines of finished iron and steel products and crude steel have failed and plans are now being perfected, it is understood, for

a general readjustment. It is known that the serious cutting of the regular rates on several important products by independent producers has been responsible for the hesitancy on the part of buyers to come into the market for their usual requirements. The jobbers, who in former years replenished their stocks in January, are buying only for immediate needs. In order to bring out this business it has been decided to make a general cut. While these reports have not been officially confirmed by the large interests, indications are that they are not without foundation. Instead of small reductions as were made at the meeting of steel concerns in New York last June it is said the cuts will range from \$4 to \$7 a ton and will include billets, sheet-bars and all lines of finished products. While there has been no cutting of merchant pipe and tinplate, these products will be reduced owing to the cut in raw material. Steel bars will not come down very much, as prices are already low. Steel rails alone will not be affected. The uncertainty regarding the tariff has affected the iron and steel trade and it is expected that this will be removed soon after Congress meets. It is not believed here that any radical changes will be made. With the tariff and the price question adjusted satisfactorily there will be no apparent reason for further delay in buying.

Pig Iron—There is no pig-iron market, the only business being the shipping of iron on old contracts. Production is not being curtailed and stocks are piling up. The Carnegie Steel Company on Monday started its new No. 6 blast furnace at the Ohio works, Youngstown. It will make basic iron for the new open-hearth furnaces. The Midland Steel Company which operates one blast furnace at Midland, 25 miles below Pittsburg on the Ohio river, plans to build another furnace and contracts will be let in a short time. The new furnace will have a capacity of about 90,000 tons of foundry iron annually. Pig-iron quotations, in the absence of actual transactions, are nominal as follows: Standard bessemer, \$16; malleable bessemer, \$15.50; basic, \$15.25; No. 2 foundry, \$15; gray forge, \$14.25, all f.o.b. Valley furnaces.

Steel—There is no change in the market for crude steel. Billets are held at \$25 and sheet-bars, \$27.50, Pittsburg. Plates are still quoted at 1.60c. but sales are made at \$2 a ton less. Merchant steel bars are firm at 1.40 cents.

Sheets—Cutting of sheet prices continues and sales of all sheets are at \$2 a ton under what is regarded as the official prices which is as follows: Black sheets, 2.50c. and galvanized sheets, 3.55c. for No. 28 gage.

Ferro-Manganese—There is little doing, and while there are reports of low prices, dealers continue to quote \$45.50@46. Pittsburg.

Metal Market

New York, Feb. 17—The metal markets generally continue in a rather depressed condition. Demand has not improved, and there has been no recovery in prices.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Dec. 1908...	\$ 7,358,707	\$ 5,122,538	Exp. \$2,236,169
" 1907...	1,004,441	44,448,518	Imp. 43,444,074
Year 1908...	71,215,456	50,246,099	Exp. 20,969,357
" 1907...	55,215,081	143,398,072	Imp. 88,182,991
Silver:			
Dec. 1908...	4,726,289	4,382,290	Exp. 343,999
" 1907...	4,413,698	4,222,036	" 191,662
Year 1908...	51,837,671	42,196,966	" 9,640,705
" 1907...	61,625,856	45,912,360	" 15,713,496

Exports from the port of New York, week ending Feb. 13. Gold, \$3,852,000, chiefly to Buenos Aires; silver, \$756,194, chiefly to Paris and London. Imports: Gold, \$136,583, from Central and South America; silver, \$104,203, from the West Indies and Mexico.

The mint price of gold in France is 3444.44 fr. per kilogram. A coinage charge of 7.44 fr. per kg. is deducted, making the net price paid for gold 3437 fr., or \$663.34 per kg. This is equal to \$20.63 per troy ounce.

Gold—The price of gold in the open market in London continues unchanged, 77s. 9d. per ounce being paid for bars and 76s. 4d. per ounce for American eagles. The Bank of England this week took nearly all the gold offered, including arrivals from the Transvaal and Australia. The Bank of France is still out of the market. In New York an additional shipment of \$500,000 is reported to Argentina, and it is generally expected that more gold will go out soon.

Platinum—The market is very dull and sales are lighter than for some time past, although they are better than at this time a year ago. Prices continue unchanged, dealers quoting \$23.50@24.50 for refined platinum; \$26 per ounce for hard metal and \$19@21 per ounce for scrap.

Our St. Petersburg correspondent writes, under date of Feb. 4, that prices are unchanged both in Ekaterinburg and in St. Petersburg. The demand is good, especially from Paris. The small miners expect loans from the State bank and an increase of prices as a result. A conference on the question of the loans is to be held soon. The quotation in St. Petersburg is 19,800@20,000 rubles per poed; at Ekaterinburg, 5 rubles per zolotnik, for crude metal, 83 per cent. These prices are equivalent to \$10.00 and \$18.80 per oz., respectively.

Silver—The market has been fairly steady the past week, declining to 235½d. in London on selling by Chinese banks. The market closes steady at 23 11 16d. on buying by India bazars.

SILVER AND STERLING EXCHANGE

Sterling Ex.	4.8725		4.8720	4.8710	4.8710	4.8695	

New York quotations, cents per ounce troy, fine silver; London, pence per ounce sterling silver, 0.925 fine.

Shipments of silver from London to the East, year to Feb. 4, reported by Messrs. Pixley & Abell, London:

	1908.	1909.	Changes.
India.....	£ 799,900	£ 467,560	D. £ 332,340
China.....	451,400	80,000	D. 371,400
Straits.....		51,000	I. 61,000
Total.....	£ 1,251,300	£ 608,560	D. £ 642,740

Imports for the week, £180,000 from New York. Exports, £11,500 to India.

Copper, Tin, Lead and Zinc

Feb.	Copper.		Tin.	Lead.		Zinc.
	Lake, Cts. per lb.	Electrolytic, Cts. per lb.		New York, Cts. per lb.	St. Louis, Cts. per lb.	
11	13½ @ 13½	13 @ 13½	59	28½ @ 28½	4.00 @ 3.87½	4.72½ @ 4.75
12						
13	13½ @ 13½	13 @ 13½		28½ @ 28½	4.00 @ 3.87½	4.72½ @ 4.75
15	13½ @ 13½	13 @ 13½	58½	28½ @ 28½	4.00 @ 3.87½	4.72½ @ 4.75
16	13½ @ 13½	13 @ 13½	58½	28½ @ 28½	4.00 @ 3.87½	4.72½ @ 4.75
17	13½ @ 13½	13 @ 13½	58½	28½ @ 28½	4.00 @ 3.87½	4.72½ @ 4.75

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125¢ below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium. Spelter prices given are at St. Louis; prices at New York, Feb. 11-17 were 0.15¢ higher than St. Louis each day.

Copper—The lower prices have so far not attracted buyers. On the contrary, consumers, both in this country and in Europe, have withdrawn altogether except for their immediate needs, as they hope to force a further reduction. Business on this account has been more or less of a retail character. Some Lake has been reported sold to domestic consumers under special conditions at a price a little above the real market, but this grade has been freely offered by leading interests at 13½¢, without drawing much business. Electrolytic has been dull. The market closes lower at 13½¢@13½¢, for Lake copper; 13½¢@13½¢, for electrolytic copper in ingots, cakes and wirebars. The average of the week at which business in casting copper has been done is 13¼@13 cents.

Copper sheets, cold-rolled, 20c.; hot-rolled, 19c. per lb., base. Copper wire, 15½¢ base, carload lots at mill.

The speculative market in London has

been a very uninteresting affair throughout the week and prices close lower and barely steady at £58 7s. 6d. for spot, £59 2s. 6d. for three months.

Statistics for the first half of the current month show a decrease in the visible supplies of 700 tons.

Refined and manufactured sorts we quote: English tough, £62 10s.; best selected, £61 10s.@£62 10s.; strong sheets, £73 10s.@£74 10s.

Exports from New York and Philadelphia for the week are reported at 2571 long tons copper. Our special correspondent states the exports from Baltimore at 426 tons.

Supplies, deliveries and visible stocks of copper on Jan. 31, as reported by Henry R. Merton & Co., Ltd., London, in long tons:

	1908.	1909.	Changes.
Imp. in Jan. N. America...	36,143	19,296	D. 16,848
Chile.....	3,000	3,000	
Australia.....	1,668	2,600	I. 932
Other countries.....	5,769	6,278	I. 509
Total.....	46,580	31,178	D. 15,402
Stocks, Jan. 1.....	19,710	55,677	I. 35,967
Total supplies.....	66,290	86,850	I. 20,560
Deliveries in January.....	45,630	38,916	D. 11,715
Stocks, Jan. 31.....	20,660	62,935	I. 31,275

Deliveries in January, 1909, included 400 tons reshipped to America.

Tin—The London market has become very strong. It develops that supplies are again concentrated, and as shipments from the Far East are of moderate volume only, holders of the present supplies are in a position to advance the market easily, if they decide to do so. The close is cabled at £130 5s. for spot, £131 15s. for three months.

A fair business has been done in this market, especially among dealers, and prices have advanced at the close to 28½ cents.

Lead—Orders are few and far between and the market is depressed at 3.85@3.87½¢. St. Louis, 4@4.02½¢. New York.

The London market has had a rally, due to covering of the bear contingent, but closes somewhat below the best price at £13 6s. 3d. for Spanish lead, £13 8s. 9d. for English lead.

Spelter—The lower prices have not as yet helped business, the uncertainty of the future of the iron and steel markets being the main restraining influence. The close is unchanged and easy at 4.72½@4.75 St. Louis, 4.87½@4.90c. New York. More or less speculative business in spelter is going on.

The close in London is cabled at £21 7s. 6d. for good ordinaries, £21 12s. 6d. for specials.

Base price of sheet zinc is 7c., f.o.b. La Salle-Peru, Ill., less 8 per cent.

The European Zinc Syndicate is to continue for two years from Jan. 1, 1909. One important maker—Giesche's Erben—did not go into the agreement, but doubtless will act in harmony with the syndicate.

Other Metals

Antimony—The market is almost dead for the present. In the absence of business prices are difficult to quote, but any sales must be made at a shade below last prices. Cookson's may be quoted 8½¢; Hallett's, 8¢; with 7½¢@7¾¢. for ordinary brands.

Aluminum—There are no new developments in this metal. The Aluminum Company of America continues to quote 24c. base for No. 1 ingots; 33@34c. base for sheets. Foreign metal is still offered at 22c., New York delivery. No considerable sales are reported.

Quicksilver—The market is quiet and business mostly of a retail order. Prices are unchanged, New York quotations being \$45@46 per flask of 75 lb. San Francisco quotations are also unchanged, being nominal at \$45@46 for domestic business and \$43@44 for export. The London price is still £8 7s. 6d. per flask, but down to £8 5s. is quoted by jobbers.

Nickel—Large lots, contract business, 40@45c. per lb. Retail, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. These quotations are for spot nickel. The price for electrolytic is 5c. higher.

Cadmium—In 100-lb. lots, 75c. per lb., at Cleveland, Ohio.

Magnesium—This material is offered in New York at \$1.25 per lb. in 100-lb. lots. The price is \$1.40 per lb. for 5-lb. lots.

Petroleum Exports

Exports of mineral oils from the United States in January, in gallons:

	1908.	1909.
Crude.....	5,746,334	13,043,008
Naphthas.....	2,162,176	6,001,809

Residuum.....	3,399,627	8,457,198
Total.....	105,122,057	120,536,356

Paraffin is included in lubricating oils. Increase this year, 15,414,298 gal., or 14.7 per cent.

Zinc and Lead Ore Markets

Platteville, Wis., Feb. 13—The highest price paid for zinc ore this week was \$38; the base price for 60 per cent. zinc was \$36@37 per ton.

Lead ore, 80 per cent., sold Tuesday at \$50 per ton, but offerings were later lowered to \$46 per ton.

SHIPMENTS, WEEK ENDED FEB. 13

Camps.	Zinc ore, lb.	Lead Sulphur ore, lb.
Platteville.....	576,240	154,200

		1,315,600

There was shipped in the three weeks previous, not heretofore reported, from Highland, 400,740 lb.; from Linden, 367,650 lb.; from Harker, 280,970 lb. zinc ore; from Linden, 50,160 lb. lead ore.

There was shipped this week to the American Zinc Ore Separating Company 146,100 lb.; to the Joplin Separator Works, 271,010 lb. zinc ore.

Joplin, Mo., Feb. 13—The highest price reported paid for zinc sulphide ore was \$40, the base ranging from \$35 to \$38 per ton of 60-per cent. zinc. About 150 tons sold on the highest base, purchased on Tuesday when a blizzard was predicted by the weather bureau. There was no change in zinc silicate, which sold on a base of \$19@22 per ton of 40-per cent. zinc and as high as \$26. It is conceded the bottom has been touched, the market indicating a slightly increased strength at the week-end. Nearly half the lead shipment was from purchases of the two previous weeks, which sold at \$52@53 per ton, but the highest offering of this week was \$51, closing the week at \$50 per ton.

Mine wages have generally been reduced to the level of last year and with almost every day ideal for outputting the production continues strong, but the heavy shipment this week exceeded the output

NOTE—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

about 500 tons, reducing the bin stock to approximately 6500 tons.

Chemicals

New York, Feb. 17—The general situation continues unchanged from our last report. Business is quiet and without any animation.

Copper Sulphate—While demand is still fair, prices are a little lower than last week. The present quotations are \$4.60 per 100 lb. for carload lots, while \$4.85@5 per 100 lb. is asked for smaller parcels.

Arsenic—The market is quiet with small sales, but prices are unchanged. Current quotations are 3@3½¢. per lb. for white arsenic.

Nitrate of Soda—Trade is rather dull. Prices are unchanged, spot nitrate selling for 2.15¢. For futures 2.12½¢. is asked for all positions.

Mining Stocks

New York, Feb. 17—The general stock market has varied from day to day without much significance. Business has been quite moderate in volume, and prices have advanced and receded alternately. Early in the week there was a slightly stronger tendency, but this was followed by a weakening in quotations, and the close is near the point of depression. It is claimed that the tone is good, but the activity is lacking.

On the Curb there was a good deal of trading in the copper stocks, but the close showed some weakness in nearly all the prominent companies. Only one or two held up to the earlier level. The Nevada gold stocks were a little more active than recently, but without any gain in prices. Cobalt stocks were in fair demand. There was free buying, but no advance.

Boston, Feb. 16—There has been prime speculation in the Lake mining issues, particularly those that have got a Calumet & Hecla tag attached to them. Notwithstanding denials, it is believed that negotiations for the taking over of the Bigelow properties by Calumet & Hecla interests have been practically concluded and it is only a matter of detail which prevents an official announcement. There has been some response in other stocks, but it has been feeble. The continued weakness of the metal and the lack of demand mitigates against any sustained upward movement. The closing of the exchange over from Thursday until Monday tended to restrict business and make a short week of it. The declaration of regular quarterly dividends of \$1 each by the North Butte and the Quincy companies had no effect, marketwise.

Isle Royale and Superior Copper divided attention for a spell. The former sold up \$4.50 to \$33, maintaining its strength, and

Superior rose \$6.25 to \$45.25. In the case of the former it is believed that it occupies a strategic position in Calumet & Hecla's plans. In Superior favorable mill runs have been the cause of the speculation largely.

Atlantic rose \$2.50 to \$17.75. Favorable underground developments are reported from that quarter and it is said to be earning mining expenses. La Salle also came in for a rise, moving up \$2.75 to \$16.75. Osceola rose \$4 to \$136, Tamarack \$8.50 to \$88.50, Allouez \$5.50 to \$45, and Centennial \$2.75 to \$34.75.

East Butte has had a good market and rose \$1.87½ to \$13.50 on heavy trading. Boston Consolidated has been weak, falling \$1.75 to \$12.50 on free offerings.

Dominion Iron and Steel is up 15, to \$35, on the judgment awarded in its suit against the Dominion Coal Company.

Superior & Boston mining has been taken from the Curb and put on the unlisted department of the Stock Exchange. The 100,000 shares of Rhode Island Copper have been stricken from the list as practically all of its shares have been exchanged for Franklin. Contest for control of the Victoria Copper Mining Company will appear at the annual meeting Feb. 23.

Seneca and Ahmeek made new high records on the Curb, the former touching \$105 and the latter \$165. They are both Bigelow properties. The curb has temporarily suspended trading in Southwestern Development shares.

Milling at Grass Valley and Nevada City

Amalgamation, Concentration and Cyanide Treatment Are Employed,
Concentrates Being Shipped to Smelters or Treated by Special Process

BY G. E. WOLCOTT*

With the exception of the North Star and the Central mills of the North Star Company and the Pioneer mill near Nevada City for treating concentrates, all of the mills of the Grass Valley, Cal., district employ practically the same process, differing only in regard to details. In this article only one mill, the Empire, will be described; it uses the more common method, and may be taken as a typical installation.

The ore from the mine dumps directly at the Empire plant into bins from which it is fed to a large gyratory crusher situated immediately below. From the gyratory crusher which crushes to a maximum of about 2 in. the ore passes by gravity to bins below from which it is drawn into cars and trammed to the mill building. Here it is fed by automatic feeders to

true vanners. The concentrates are not treated at the mill, but are either shipped to smelters or sold to the Pioneer plant at Nevada City.

CONCENTRATION

The tailings from the vanners pass through a wooden settling box, where the coarse material is taken out, and passes to the last set of blanket concentrators. The overflow from the settling box passes to 26 canvas-covered tables arranged, as shown in the accompanying illustration. These tables are 12 ft. wide and 8 ft. long on the incline, and are made of a wooden support covered with a coarse canvas cloth. These tables are washed every half hour by means of a length of hose placed at convenient intervals. A board about 6 in. wide is hinged to the lower

the spigot discharge from the settling box, and flow over the final concentrator, a 22x60-ft. canvas-covered table.

The concentration by blankets and vanners is carried out more fully at the Empire mill than is customary elsewhere. Exact figures as to the recovery are not obtainable. The ore varies greatly in value as well as in the percentage of free gold contained. As a rule most of the concentrating mills are able to get their tailings from a \$10 mill run down to 50c. or less per ton. With high-grade rock the tailings run higher and may even reach several dollars in value.

CENTRAL AND NORTH STAR MILLS

The North Star Company has two mills in operation, one at the North Star shaft and the other at the Central shaft. Each

IDAHO-MARYLAND MINE, GRASS VALLEY, CAL.

NORTH STAR MILL, GRASS VALLEY, CAL.

1000-lb. stamps, making 102 drops per minute and crushing through a No. 7 slotted screen. The stamps give a crushing capacity of about 2½ tons per 24 hours. The discharge from the batteries passes over amalgamation plates 4 ft. 4 in. wide by 17 ft. long, set at an inclination of 1½ in 12. There is one plate for each battery of five stamps. Both inside and outside amalgamation is used, the inside plates being cleaned twice each month and the outside plates twice every 24 hours. Mercury is added at intervals in the battery. The plates are plain copper without any silver plating.

The pulp from each plate goes to amalgam boxes and then passes to two

end of the table and serves to deflect the stream of concentrates into a separate launder. The board is simply lowered by means of a rod extending to the upper part of the table where it can be reached by the operator. The tables have an inclination of about 1 in 8.

From the tables the concentrates pass to a stirring box which serves to keep the pulp in suspension and also to equalize the flow to the Gates vanner, the next machine in the order of treatment.

The tailings from the first vanner pass to a second of the same size (6x10 ft.) for concentration. Tailings from this vanner pass to two canvas-covered tables, 15 ft. square, which are washed every hour. Tailings from these unite with the tailings from the first 26 tables and with

has 40 stamps and both employ practically the same process.

The ore from the mine, after crushing, passes to the stamp battery where it is crushed through a needle-punched steel screen having 10 holes to the inch. The holes in the screen are not continuous, but are interrupted every inch for about ½ in., so that the screen is divided into squares by strips of unpunched metal about ½ in. across. By this means the screening surface is slightly reduced, but the life of the screen is increased from two to three times. This is due to the fact that the unpunched metal prevents the tearing of the screen.

From the batteries the pulp passes over silver-plated amalgamation plates, 4x18 ft., having an inclination of about 2½ in

*Mining engineer, Reno, Nev.

12. After passing over amalgam traps the pulp flows to eight Dodd buddles, making concentrates, middlings and tailings. The middlings are returned to a separate buddle on the same floor. The tailings from all of the concentrators pass to a roughing cone, 7 ft. in diameter with 60-deg. sides, from which the spigot discharge goes to the sand-collecting tanks. The overflow passes to two 5-ft. Merrill classifiers, the spigot discharge from which unites with that from the first cone and passes to the sand-collecting tanks.

CYANIDING

The sands are leached with a 0.10-per cent. cyanide solution, the total treatment taking seven to eight days. The tanks are discharged through four bottom-discharge gates by means of a revolving distributor which is here used to carry water for

Cyanide is not used in the battery solution. From the filter the slimes now pass to the first agitation tank. This is connected toward the top with a second agitation tank and this with a third, which acts as a settler. The tanks are 8 ft. in diameter by 7 ft. deep to the conical bottoms which have a pitch of 60 deg. The tanks are of the Pachuca type, the slimes being agitated by compressed air passing upward through a central cylinder. The air is under 7 to 8 lb. pressure. The pulp passes continuously through the two agitation tanks and into the settling tank. In the settler the solution from the top goes to the first Oliver filter to wash down the slimes as already described. The settled pulp passes to the second Oliver filter which extracts the cyanide solution, washes the slimes and discharges it into the tailings flume.

The total time of treatment of the

tration, wash water is added from an overhead pipe, and at the same time the suction changes so as to draw the solution through a different pipe. Just before reaching the scraper at C the valve arrangement is such that pressure is applied in the filter compartments immediately above the scraper and this, together with the action of the scraper, discharges the pulp into the proper receptacle. The change from suction to pressure takes place automatically in one compartment just before reaching the scraper and suction is again automatically restored upon leaving it. The filters in use are 7 ft. long and 10 ft. in diameter, and have a capacity of nearly three tons per hour. The weight of pulp on one side of the filter very nearly balances that on the other side, so that very little power is required for the revolution of the cylinder. These filters have been in use several months at the

SKETCH OF OLIVER FILTER

ARRANGEMENT OF FILTERS

washing out the tank instead of for pulp. The water is carried to the distributor under pressure, and no labor is used in discharging the tanks.

The slime overflow from the last cones passes to six settling tanks 14 ft. diameter by 12 ft. deep, from which the overflow is pumped to a storage tank above the mill and returned to the mill circulation. Slimes are drawn off from the settling tanks every hour to a slime-collecting tank from which they pass to an Oliver filter.

The slime-settling tanks have conical bottoms, and in discharging, the upper portion which contains a lower percentage of pulp, is left in the tank. In this way the water content of the slimes is kept lower than would be possible by discharging the whole tank. The pulp in leaving the settlers has a consistency of about two water to one slime.

The first of two Oliver filters acts as a dewaterer and the slime is washed from the filter scraper with cyanide solution.

slimes is about 6 hours. The slime heads assay from \$1.50 to \$2, and the tailings from 20 to 25c. per ton.

THE OLIVER FILTER

The Oliver filter is an invention of the superintendent of the North Star mills, and is manufactured by the Taylor Foundry and Engineering Company, at Grass Valley. It consists of a revolving cylinder, the periphery of which is the filtering surface. This is divided into 24 compartments, each of which is connected by suction and pressure pipes passing through the center of the machine. The cylinder revolves in a tank which contains the slimes and makes one revolution in from five to six minutes. The portion of the filter in the slimes is subjected to a suction corresponding to about 20 lb. air pressure, which draws and holds the slimes upon the filtering surface. In revolving to the upper part of the cylinder, the pulp is reduced to about 25 per cent. moisture. At this point, as in the accompanying illus-

North Star and Central mills with satisfactory results.

TREATMENT OF CONCENTRATES

The concentrates from both mills are treated at the Central plant. Pulp is dumped into a circular wooden tank, about 8 ft. in diameter by 8 ft. deep, from which it is discharged by means of scrapers attached to two arms extending from the center to the circumference and revolved by means of a central shaft to which they are attached. The pulp discharges through the center into a pipe line leading to an Abbe tube mill 4½ ft. in diameter by 20 ft. long. Cyanide solution is added just after leaving the tank; this washes the concentrates into the mill. The ratio of solution to solid matter is a little less than 1 to 1. The cyanide solution has a strength of 0.15 per cent. cyanide. The tube mill is run at 20 r.p.m., consuming 16 h.p. An increase of 8 r.p.m. is said to have increased the power consumption to 48 h.p. Pebbles gathered in

the creek bed near the mine are used in the tube mill; this material costs \$4 per ton at the mill. The consumption of pebbles is 40 lb. per ton of ore crushed.

The pulp from the tube mill passes over amalgamation plates and then to cone classifiers from which the spigot discharge is returned to the mill. The overflow goes to agitation tanks where it is agitated in solution for six hours. It is then decanted twice and the remaining pulp sent to a small Oliver filter. The concentrates treated run from \$30 to \$40 per ton, and an extraction during two years' run of 93 per cent. by bullion returns has been made. The consumption of cyanide is $2\frac{1}{2}$ lb. per ton treated and the total cost of treatment is \$3 approximately.

PIONEER MILL

The Pioneer mill is a small plant near

melted with a flux of borax and niter. The resulting bullion is usually 995+ fine.

Reminiscences of Goldfield, Nevada

BY MARK R. LAMB*

The scenes which occurred in Nevada camps in the early days of the great excitement were probably not equaled anywhere in the world. One thinks of the United States as a highly civilized and law-abiding nation, but what a surprise to see in the Goldfield district acts, which in Russia, are justification for wholesale deportations, and in Mexico, for the introduction of troops with ball cartridges.

Think of a camp with 37 buyers of

panion asked as he went toward the man to help him.

"Oh, no, but I've got too big a load—no whisky, but ore."

He was helped up, staggering, and then he showed us his load of ore bulging from pockets, "leg pockets" (long, narrow bags to hang down the trouser legs), and "ore harness" (double canvas shirts entirely made up of stitched pockets for ore), with finally a big double-crowned Stetson hat, capable of holding at least five pounds of ore.

"Willis, the assayer, tells me that I bring the record loads out of the Mohawk," he boasted. "The foreman had to help me out of the bucket as I came off night shift," he continued, grinning, "and he is one of those cranks who would like to kick about our taking our share."

A story, a true story, is told of two miners who, after getting a little of other people's money together in this way, took a lease and were lucky and struck "jewelry" ore. As they were "wise" they attempted to prevent high-grading. One day they caught the entire shift cleaning out a rich streak of ore.

"Here, you fellows, you can't take any of that out of this mine," one said as both covered the miners with six-shooters. "You have no kick," retorted one of the shift. "You did the same thing on the Riley lease."

"Maybe I did," was the reply, "but I did not take all the best ore, and anyway this is my lease and high-grading don't go—see?" And it stopped.

At one mill the precipitated gold, worth about \$30,000, was in the clean-up acid tank. The cutting of the short zinc was not quite finished at the end of the day, so the clean-up room was locked and a watchman placed, with the intention of completing the job the next day. In the morning the windows were found covered on the inside, a tray of "shorts" gone, and as the acid tank had been disturbed it was supposed that the settled gold in it was also gone. Great consternation reigned, but a hurried investigation showed that though an attempt had been made to scoop out the gold, the acid solution was so dense and saturated that the gold had not settled. As the clean-up turned out more gold than was expected, the loss could not have been great. Of course, the stolen gold was melted up in one of the "assay offices."

How great was the temptation at Goldfield is shown by the difficulty that the express company experienced in getting honest drivers to gather up the shipments of stolen ore from the assay offices each night. There was no real need of doing this work at night, but it "looked better."

The sudden "ups" and "downs" of life in Goldfield were simply incredible. The best places to get stories were around the gaming tables and at the club. This latter was merely a social club with no civic duties or responsibilities—a fact empha-

CANVAS CONCENTRATORS, EMPIRE MILL

Nevada City which treats concentrates from the neighboring mills. The process consists simply in roasting "sweet" and leaching with cyanide solution. A minimum charge of \$10.50 per ton at the mine is made, and returns are given of 93 to 94 per cent. of the assay value.

The gold from the cyanide solution is precipitated on zinc shavings dipped in lead acetate. The precipitated material is first treated with sulphuric acid to remove the zinc, and then with a mixture of sulphuric acid and sodium nitrate for removing any copper present. The gold is then dissolved in a mixture of 10 lb. salt, 100 lb. commercial sulphuric acid and 10 lb. potassium permanganate. This amount is sufficient to dissolve from \$5000 to \$6000 in gold. The gold is precipitated from solution with ferrous sulphate and

small lots of ore—37 competing buyers of stolen ore—37 honored citizens who would buy one pound or a ton of ore from miner or mine foreman, or would purchase bullion or zinc precipitate in any shape and quantity, knowing beyond a shadow of doubt that it was stolen from one of the three plants then in operation in the camp. The climax came when the owners of one mill advertised openly to buy bullion—and are known to have bought bullion from their own employees which was stolen from their own mill!

I remember walking in front of Cook's bank in Goldfield with a friend, who was hailed by a miner seated on the curb.

"George, come help me up!"

"What's the matter—drunk?" my com-

*Milling and cyaniding engineer, Milwaukee, Wis.

sized whenever a "vigilance committee" spirit was expected of it, though it had a large and "better element" membership. Over glasses or a little supper one would hear tales of sudden wealth which made the wonders of Aladdin's lamp fade. One fortunate fellow, known to his associates as "Dick" and now rated with seven figures after his name, told of leaving Tonopah as a laborer with a party of surveyors headed for the new camp, then called Grandpa. His pay was \$50 per month and board. It was a chance to get to a new strike at no cost. None of his party thought the camp had any merit after they had been over it thoroughly, but Dick, as he naively tells it, wanted a job after returning to Tonopah, so he boosted for Grandpa in order that the survey party be sent out again and he be enabled to get his \$50 and board. He located a number of claims in order to have something to sell, then bought a small share in one of the mines which afterward became a big producer. One little deal after another finally made a broker of him and the rest was easy. Ability to succeed was his and the opportunity presented itself.

Another man, now a millionaire, arrived at Goldfield literally broke. He slept out of doors for lack of the price of a bed, and sought the warm wall of a mud bake-oven in order not to freeze. His name is now spoken most respectfully by everyone from Pullman porter to smelter manager. In order to get to Goldfield another pawned a diamond ring—his last available asset. He is now an honored member of the Rocky Mountain Club of New York, and pawns no more.

Two men, both big fellows, came to me one morning when there was no chance for them except to shovel tailings from the tanks. It was new work for them, so they worked hard—and beat the record. This led to a contract and that month the tailings gave no trouble. But a month was all they wanted. A lease on the Mohawk soon fixed them beyond all care—unless they put the profits back into some other hole.

Labor was hard to get and harder to keep. I have decided that of all labor, battery men are the most dependable. Whether it is because he works so hard for his pay or because it takes a steady, phlegmatic man to run a battery, I know not, but he seldom quits to gamble, or in fact, for anything but a good excuse. And although he has the best chance in the world, a milhau rarely high-grades.

My first task in Goldfield was to thaw out a frozen pipe line ten miles long. The temperature was about zero. The line had been loosely and hastily laid and in some places was above ground. Money could hardly hire men for outside work. Grave diggers were paid \$20 per day, for no one was prepared with clothes for such weather, as the year before had been mild and the second year before—no one knew, as the place was uninhabited. But

finally by building fires with sage brush, digging frozen ground, drilling into the pipe, and moving along bit by bit as the water showed at the drill holes we got the water flowing through the pipes again.

The railroad to Goldfield made money. It paid for itself in six months. Strange things happened during the first few months after the completion of the branch. For instance, the company that I was working for was anxious to get in a small boiler for a mill then being built. The freight agent would not receive it, saying that the road was already blockaded with freight, but in his capacity as express agent he gladly loaded the boiler into a freight car, charged us express rates and sent it through. One leaser, immediately after securing a good block of ground, hurried to Denver, bought his hoisting machinery, chartered a special train and returned to Goldfield with the machinery in less than passenger time. It was expensive, but his lease allowed him only six months and every moment counted. He sunk 300 ft., found rich ore and cleared just \$50,000 over all expenses in that time.

Speaking of leasing brings a flood of interesting reminiscence. While I was at the Combination mill our assayer and samplers regularly tested the ground as fast as it was opened up by the various leasers, so that we actually knew before the leasers themselves, when good ore was struck. One leaser on the extreme end of the Combination ground had sunk his shaft within a few feet of the endline of the claim. One day the assayer reported that the ore assayed \$600. We were all excited, went down to see the ore, studied the formation and decided that the ore must certainly run into the adjoining claim. The stock of the latter was then selling at 20c. a share. In spite of all favorable indications, only two of the staff had the nerve to buy—and the stock went to 85c. in two days. It can easily be imagined how we felt because we had not bought. An "investment" of \$500 on margins would have made a royal profit of \$25,000. I hate to spoil this, but must add that the men who did buy, kept on buying until the stock dropped again, since the ore did not go where we expected it. One of these men is still in Goldfield, has made and lost many fortunes (on paper), but still has his salary to live upon.

One newsboy in Goldfield got the speculative fever, but he was cold blooded and took no chances. Jimmie was a favorite with the brokers, and kept his mouth shut, so when one of them knew of a planned manipulation (it required an expenditure of only \$1000 or so of real money to cause a flurry), Jimmie was tipped off and so cleared a little profit. His bank account soon reached \$10,000.

The margin between success and failure is sometimes very narrow. One leaser—an Italian—missed the ore on his

block of ground, spent his grub-stake of \$5000, and in disgust sold his lease for \$3000. His successor, a clever young fellow with several years of experience in prospecting and mining, found ore. It was of such grade that he took his bed and tent to the ground, using them to cover and catch the rock blown out by the first few shots. He took out over a hundred thousand in the first two weeks.

On another lease a party of Easterners had begun sinking in a spot which brought them ridicule from all sides. After spending all their capital they had agreed that they were wrong: one of the party gave up in disgust and started for Chicago to begin life over. Just out of Denver he received a telegram from his partners, "Better come back. Ground looking better." His remarks will not bear repeating. This same hope had been held out ever since the shaft had been started. Within a few hours another telegram was handed him that read, "Hurry back. Have cut a small stringer of rich ore."

"Porter," he said, "if you bother me with another telegram before morning there will be a nigger missing on this car." But at 12 p.m. the conductor brought him a telegram to the smoker. It said: "Have cut seven feet of \$900 rock." That was more than he could stand so he started back. This was the first of the rich leases on the Mohawk mine, which has produced literally tons and tons of gold, for one carload, alone, of special picked ore contained more than a ton of pure gold.

A friend took me to see a mine of his which was very promising. He had recently bought it and was building a mill on the ground. I presume thousands of men had been over the claim after its discovery, examining the vein, commenting on the coarseness of the gold and envying the lucky owner. I followed suit. He gave me specimens which were more than half gold. After I had returned to Goldfield and had almost forgotten that mine, a wise prospector came along and took a lease on the surface dirt. Just the loose stuff, mind you, with no rights to do anything but dry-wash the loose gold. For weeks he took out \$1500 a day clear profit. Now, why did not I think of that?

All short trips to examine mines were made in autos. As there were few roads the autos had to run over sage brush, boulders and cactus, but serious accidents were rare. The expense of such trips was not taken into consideration. If a new discovery was made it was simply a question of getting there first at any cost. One claim near the original discovery would sell for the price of several autos, whether it had good indications or not. Such claims are always "extensions" of the original discovery. Autos have made the trip from Tonopah to Rhyolite and back in a day, a recorded distance of more than 250 miles.

Electric Hoists as Adapted for Coal Mines

The Numerous Advantages of Electrical Winding Are Discussed,
and the Most Improved Equalizing Systems Are Compared in Detail

BY R. H. ROWLAND*

In most of our modern collieries and mines, electric haulage is adopted, if not in its entirety, at least to some extent, and its advantages over mule and steam haulage, from results of experience have been tested and proved at various mines throughout the United States and foreign countries. Briefly, the advantages consist of an increased production at a decreased cost, a very material factor to the operator.

The majority of colliery and mine operators, at whose mines are installed steam hoisting plants, are not desirous of replacing their installations by electrical machinery, although these steam plants might be inefficient and uneconomical. Perhaps the chief reason for their objection to the installation of electricity is owing to the initial cost of installing, and the consequent disposal of the original equipment. However, at many mines operated in countries where fuel is expensive, large companies have already begun to tear out steam hoisting plants and substitute electrical installations.

Winding engines may be driven by three-phase induction motors, or by direct-current motors, either direct-coupled or through gearing. For large winders, the adoption of direct-coupled motors is preferable, and they become a necessity for 400 h.p. and above. The inertia of direct-coupled motors is considerably less than that of geared motors, and small inertia is of importance when high acceleration and high rope speeds are required. Three-phase induction motors may be used in connection with three-phase power transmission. Slow-speed induction motors of about 60 r.p.m. should be built with 25 cycles, but not for 60 cycles, owing to the poor performance, and the high price.

SELECTING THE STYLE OF MOTOR

Three-phase motors may be used whenever the losses in the starting resistance are a small percentage of the total power consumption, and when the weight of the drum or friction wheel is low. In this case the unbalanced load produces a sufficient retardation, without regenerative braking. If the power can be advantageously generated in a direct-current unit in the vicinity of the winding engine, direct-current motors can be successfully adapted. Also, whenever the

conditions given above for induction motors are not fulfilled.

ADVANTAGES OF ELECTRICAL WINDING

Electrical winding has different advantages compared with steam winding engines. Some of these advantages are in the greater flexibility and uniform torque of the electrical motors, which reduces the flywheel effect of the winding engine to the minimum amount, while the steam engine must in many cases have a greater flywheel effect due to its reciprocating action. These features of electrical winding result in many detailed advantages, such as smaller boiler engine capacity, the practical elimination of losses by heat radiation of a plant with considerably smaller capacity, no overload or variable strain of the material and apparatus of the power house, and lastly, the possibility of centralization of the production of energy necessary for all the machinery in the mine. Other advantageous features of electric hoisting are the extremely simple and smooth action of the controlling apparatus of the winding engine, and almost constant accelerations, (not obtainable with steam hoists).

Electric hoists, therefore, insure less maximum speed with the same time per wind, or with the same maximum speed less time per wind, this latter fact resulting in an increased carrying capacity of the shaft, or in other words an increased output of the mine.

THE SAVING IN FUEL

Perhaps the most important advantage is the considerable saving in steam or coal per unit of material extracted. This, however, applies only in the event of it being possible to erect the electrical equipment so that the power station is able to produce the energy with practically 100 per cent. load factor, and it is only in this fact that a saving can be obtained. In this way the electrical energy is generated with the maximum possible efficiency.

The power demand of winding engines varies within wide limits; during the decking period no power is consumed by the winding motor, while during the accelerating period the load on the winding motor is increased to two or three times the average load calculated for the total time. The load curve, therefore, will be periodic, and its shape entirely dependent on the mechanical out-

lay of the winding engine. Such a load curve is shown in Fig. 1 by the letters *N A B C D E X*, which embody an area. The average ordinate of this polygonal line gives the mean power for the winding motor, and in order to obtain a constant load following the line *A D a d*, a means must be found for storing during the pause, the energy represented by the area *E D a F* and delivering same to the winding motor during the period of overload *A B C D*. This result can be obtained by using a heavy flywheel, arranged so as to absorb energy during the interval *D a* and to give back same during the time *a d*, so that it will thus be possible to install a power station working continuously with 100 per cent. load factor and designed for the average power demand. Such a power station would result in a "considerable saving in steam or coal per unit of material extracted," as previously stated.

EQUALIZING SYSTEMS

There are different load equalizing systems, chief among these are the Ilgner motor-generator system, the Ward-Leonard system, and the Westinghouse converter-equalizer system. The Ilgner system is practically an adaptation of the Ward-Leonard motor-generator system. The motor of the motor-generator is either an induction motor with slip rings (Fig. 2) or a direct-current shunt motor (Fig. 3). These diagrams show the Ilgner system mostly used at the present time in order to arrive at the equalizing effect above referred to.

The generator is shunt wound and connected to a direct-current shunt-wound winding motor. The generator and the winding motor are separately excited, and by varying the excitation of the generator, any voltage between minus maximum and plus maximum may be applied to the winding motor terminals. The operation is as follows:

The motor (*A*), Fig. 2, is first started and brought up to speed with the flywheel (*B*), dynamos (*C*), and the exciter (*G*) on the same shaft. The field circuit (*D*) of the exciter is then closed and current is supplied to the field winding (*E*) of the winding motor. By moving the controller (*F*), which consists of a reversible field rheostat, the field current of the generator, and consequently the voltage at its terminals, can be varied to any desired degree.

The motor coupled with the flywheel

*Mining engineer, 255 West Forty-fourth street, New York City.

must be allowed to slip in order to let the flywheel discharge a part of its kinetic energy. This is obtained by inserting a resistance in the secondary of the induction motor (Fig. 2), or by regulating the field excitation of the direct-current shunt-wound motor (Fig. 3). The regulation is arranged so as to work automatically and keep the input of the motor constant. The speed variation with an induction motor cannot, for economical reasons, be higher than 10 per cent. of the maximum speed, while with the direct-current shunt motor the speed variation may be as high as 30 per cent.

WESTINGHOUSE CONVERTER-EQUALIZER

The Westinghouse converter-equalizer may be used in conjunction with either alternating or direct-current motors. The equalizer for alternating-current motors, shown in Fig. 4, consists of a rotary converter (A) connected through transformers (B) to the high-tension transmission lines. The rotary converter on its direct-current side is connected to a direct-current machine (C) with flywheel (D), and is compounded in a special way, so as to compensate automatically for the magnetizing currents of the induction motors in the system. The voltage of the direct-current flywheel machine is controlled automatically by a quick-acting regulating apparatus (E) from the high tension transmission line through series transformers. This enables the converter-equalizer to discharge energy into the high-tension system whenever the load of the latter is greater than the constant station output, and to store up energy in the flywheel whenever the power demand in the high-tension supply system is less than the constant output of the station.

When no load is on the high-tension system, the rotary converter is acting with 100 per cent. power factor, giving up to the flywheel the total constant station output until maximum speed is reached. The capacity of the flywheel is made sufficiently large to take care of the overload periods of the high tension system. The flywheel machine is preferably built for high speeds in order to obtain high electrical efficiency combined with light weight. The flywheel may have a maximum slip of 40 per cent. of its maximum speed, but in ordinary service 30 per cent. will be sufficient.

The over-all efficiency of this converter-equalizer (the energy input divided by the energy output) is about 70 per cent., which can at least be compared to a chemical accumulator, besides having the advantage of a cheaper price for the output, and a smaller cost for maintenance and repair.

In view of the fact that this converter-equalizer is only handling the overload and underload energy, which represents but a small amount of the constant sta-

tion energy delivered, the efficiency of the whole system will be considerably higher, and for the small loss in the load equalizer, a gain of at least 8 to 10 times the amount results in the power station. This is due to the fact that without the load equalizer a larger station capacity to withstand the maximum load had to be provided, and is operated with a very small load factor. The average load fac-

FIG. 1. THE LOAD CURVE IS DEPENDENT ON OUTLAY OF WINDING ENGINE

FIG. 2. ALTERNATING CURRENT POWER TRANSMISSION

FIG. 3. DIRECT CURRENT POWER TRANSMISSION

tor of the winding engines in most cases is not higher than 15 to 20 per cent., and the same load factor is on the station without the load equalizer.

This converter-equalizer in connection with alternating-current motors may be installed at any suitable place on the alternating-current system, and need not be situated near the winding motor.

The equalizer for direct-current motors shown in Fig. 5, consists of a rotary converter (A) connected to the alternating-current mains in the same way as is shown in Fig. 4. The direct-current side is connected to a direct-current machine

(B) fixed on the same shaft with a flywheel and a direct-current machine (C). This latter machine being connected in series with the machine (B) acts as a voltage regulator in order to obtain a variation of voltage on the winding motor terminals (D) between minus maximum and plus maximum.

The direct-current voltage of the machines (A), (B), (C) is one-half of the maximum voltage of the winding motor (D), so that if the latter is built for 500 volts, the machines (A), (B), (C), will have 250 volts each.

When the winding motor (D) has to be started, the voltage of the regulating machine (C), will be opposite to that of the machine (B). By decreasing gradually the voltage of (C) to zero, and increasing it in reverse direction any desired tension between zero and maximum may be applied to the winding motor. In order to regenerate it is only necessary to decrease the voltage impressed on the winding motor.

The energy will always be taken from the alternating-current supply circuit with a 100 per cent. power factor; or a leading current may be sent into the same by properly regulating the shunt field of the rotary converter. The voltage regulating machine (C) can sometimes be omitted, and the winding motor (D) started by resistance. This is applicable in all cases where the losses in starting resistance are very small.

THE LOAD VARIATIONS ARE EQUALIZED

This equalizer will also act so as to equalize at the same time the load variations on the alternating-current circuit produced by any other motors. It may be compounded in a suitable way in order to regulate the power factor of the whole alternating-current system. If it is not desired to equalize the entire alternating current load, the automatic regulator will be connected into the direct-current side of the converter and the motor magnet operated by direct current. It is essential that this converter-equalizer for direct-current motors be installed in the neighborhood of the winding engine.

The direct-current winding motor will usually be shunt wound, particularly if electric regeneration is required, but it may be series wound if used in connection with large haulage gears.

COMPARISON OF SYSTEMS

It may be interesting to engineers and others concerned to here make a comparison of the advantages and disadvantages of the Ilgner motor-generator system and the Westinghouse converter-equalizer system for the operation of winding engines.

The Ilgner system uses a motor generator which transforms the total current consumed by the winding motor from three-phase energy into direct current,

while the Westinghouse converter-equalizer transforms only that amount of energy into direct current, and back into polyphase currents, which is in excess or below the constant output of the station. The former is an indirect system and the latter a direct system.

Owing to the fact that the Ilgner system has a direct-current motor on the winding engine, which, if geared to the winding drum, might cause trouble, due to sparking on account of the vibrations on the pinion, this trouble is eliminated by the polyphase induction motor with slip rings which is adopted for driving the winding engine in accordance with the Westinghouse system.

In underground work, and especially in coal mines, induction motors are generally adopted; the use of direct current for the winding engine would therefore make it necessary to use two different electrical systems. With the Westinghouse equalizer, it would only be necessary to use polyphase current in the mine.

As stated previously, the Westinghouse converter-equalizer may be installed at any convenient place in connection with the high-tension transmission system, in the power station in the center of the power consumption area, or near the winding engine. So that if the winding engine is located at a place which is not easily accessible, repairs can be made at a place which is convenient, and where the converter equalizer is installed. If, therefore, as often occurs, the mine is situated at a remote place in the mountains, it will be extremely inconvenient to transport spare parts and make repairs in case of any damage to the heavy motor generator used in connection with the Ilgner system, which it is essential must be installed near the winding engine at the shaft.

Should any irregularity happen with the motor generator of the Ilgner system, it is necessary to shut down the winding engine, but with the Westinghouse system, if the station is unable to stand the overloads, the winding engine can still continue its operation, although at a reduced load.

Another advantage of this equalizer is that if the same is handling light loads, as is often the case at night time, so that no equalizing of the station is necessary, it may be shut down; but the motor generator of the Ilgner system cannot be shut down, although its load equalizing effect is not needed under this condition, and therefore a great loss with a low load factor results.

THE MOTOR-GENERATOR MUST BE SHUT DOWN

During long pauses in the operation of the winding engine, it is advisable to shut down the motor-generator of the Ilgner system, owing to the fact that

when the flywheel is started again by the induction motor, there is produced such an overload shock on the power station that in order to avoid it, it is preferable to run the motor-generator for a longer time without load; with the Westinghouse equalizer, however, during long pauses, the machine can be shut down, owing to the converter acting with 100 per cent. power factor, the light flywheel when started again does not re-

large high-power winding engines, transportation would in many cases be impossible.

The flywheel of the Westinghouse converter-equalizer can charge and discharge three times as much of its total kinetic energy as the Ilgner flywheel, and this enables it to have one-third the weight. A light flywheel, too, can be made in one piece, and transport by railroad does not entail any difficulties. The flywheel, also, can be made for any size of winding engine.

It is necessary that the capacity of the Ilgner generator be sufficient to handle the peak load, but the capacity of the flywheel machine of the Westinghouse equalizer need only be sufficient to handle the difference between the peak load and the average load; also the speed can be higher and the cost lower, in the former case the speed is less than the latter. The transport of heavy flywheels in mountainous districts is difficult, while light flywheels can be moved without trouble.

The Ilgner flywheel must be built of a large diameter in order to obtain a sufficient speed at the radius of gyration, but the Westinghouse flywheels with high speeds are built with small diameters.

Finally, the installation of the Ilgner motor-generator means in many cases the erection of a sub-station and therefore de-centralization, while the great advantage of polyphase high-tension transmission is the absence of sub-stations with rotating machinery which needs inspection. The installation of the Westinghouse equalizer with an induction motor for winding does not necessitate the erection of a sub-station. It should, in fact, be preferably placed in the power station if general conditions permit.

There are various schemes of electrical winding plants to suit the several conditions; however, it would go beyond the scope of this article to embody the whole, and while much has been said in the engineering papers regarding the adoption of flywheels as being unsatisfactory, the Ilgner system of electrical hoisting has found much favor on the continent.

In figuring the mechanical data, the details for the engineer to carefully consider are the shaft, loads, speeds, decking operations, rope, pit-head sheaves, winding gear, and position of winding engine; the electrical data embodies the power house, etc.

The friction wheel so largely adopted on the continent is a factor to be recommended whenever winding engines driven by electrical motors are to be considered, owing to the fact that the small weight of the friction wheel, and the consequent large reduction of the total mass allow the winding motor, as well as the equalizing plant, to be much smaller, and therefore cheaper. The wear and tear on the

FIG. 4. EQUALIZING SET WITH A. C. MOTORS

FIG. 5. EQUALIZING SET WITH D. C. MOTORS

quire more than approximately one-quarter of the apparent power of the Ilgner motor-generator.

The flywheel of the Ilgner motor-generator can only charge and discharge a small amount of its total kinetic energy, which fact makes it very heavy. The heavy flywheel has to be built up in one or more solid steel disks in order to get sufficient strength with the high speeds, and it is a very difficult matter to transport these flywheels on railroads, owing to the limits of the loading gage, and for

rope is less than with the drum winder, and the possibility of overwinding, causing the cage to run up against the pit-head sheaves, is avoided, owing to the fact that the rope will slide on the wheels as soon as the cage reaches the bottom of the pit; lastly it is impossible to exceed a given strain on the rope, as same will slide should the pull exceed a certain maximum. Regarding the costs of installation of the respective equipments, this is entirely dependent on the conditions to be fulfilled, but it may be generally taken that they compare favorably.

The Crab Locomotive in Coal Mines

The Jeffrey Company, of Columbus, Ohio, has recently added to its line of electric mine locomotives a new type of gatherer known as the "crab locomotive." With the common type of gathering locomotives provided with a reel, it has been difficult to pull loaded cars out of rooms driven to the dip. Again, where the tracks are level, it is often found economical to push the empty into the room by hand, so that mechanical means are required only for hauling out the loaded cars. The crab locomotive was designed to overcome these faults, and is supplied with a small winding drum, or crab, which is mounted on the power end of the locomotive. On this drum is wound 350 ft. of $\frac{1}{8}$ -in. flexible wire cable, which latter is used for pulling the loaded cars from the room and out onto the entry track.

In mines where the double-entry system is used, the locomotive usually hauls a trip of empty cars into one entry and drops them off at the rooms where they are required. Returning on the other entry, it stops in front of each room where a loaded car is ready. The trip rider then drags the cable into the room, attaches it to the car and signals the motorman who starts the crab motor and pulls the car out of the entry track. The locomotive then either pulls the car to the next room, or leaves it standing until as many cars have been drawn from the room as are required to make up a trip. These loads are then coupled up and hauled to the parting. On the return trip the empty cars are distributed in the entry from which the loads have just been removed, and the locomotive gathers a load of cars from the entry which was supplied with the empties on the preceding trip.

Where the single-entry system is employed, the locomotive usually runs in with a train of empties. Stopping successively in front of the rooms in which loaded cars are ready, it hauls each car to the entry track and pushes it ahead to the next room, dropping off an empty to replace each loaded car taken out. When all empties have been distributed, the

motor then proceeds to the parting with the loads gathered. By each of these methods a locomotive can gather from 75 to 200 cars per day, depending upon local conditions.

The crab device is made as compact as possible; the drum is driven by the gearing, through a friction clutch, which acts not only as a smooth starting device for the cars, but also as a safety device in case a car becomes derailed, or the motorman fails to throw off power until the car bumpers strike those of the locomotive. Without this friction arrangement the cable would in such cases break, or serious injury would result to the gearing or motor itself.

The motor which actuates the crab being entirely separate from the locomotive motor, is controlled by a separate starting box, and when the car approaches the entry track the motorman starts the locomotive ahead. As it advances past the switch point the car follows and runs out upon the entry track without either the locomotive or the winding of the crab being stopped. The crab may be stopped when the car strikes the locomotive, but the locomotive need not stop until the room is reached from which the next load is to be hauled. The cable may be paid out from either end of the locomotive. Ordinarily, however, it is more convenient to take the cable out past the motorman, as that end of the locomotive is then opposite the room mouth, and the motorman can watch the light carried by the trip rider, and can see him signal to start winding. He can also watch the car to better advantage as it takes the switch, and can stop instantly if it should become derailed.

One advantage claimed for the crab locomotive is that, except where there are rooms driven to the rise at so great a pitch that the cars cannot be pushed into them by hand, it may replace animal haulage at once without making any changes in the track or conditions in the rooms. When rooms are driven to the rise, it is impracticable to use the crab device for hauling cars into these chambers.

Testing Explosives

Director George Otis Smith of the United States Geological Survey has sent a letter to manufacturers of explosives announcing a series of preliminary tests of such explosives in the presence of inflammable gas, coal dust and the like. The tests are to be made in the experiment station at Pittsburg, Penn., and the object will be to make official studies of articles which manufacturers may desire to have certified with regard to their permissibility for use in mines containing gas or dust in dangerous quantities. The conditions of the test are as follows:

(1) The manufacturer is to furnish 100

lb. of each explosive which he desires to have tested; he is to be responsible for the care, handling and delivery of this material at the testing station on the United States Arsenal Grounds, Fortieth and Butler streets, Pittsburg, Penn., at the time the explosive is to be tested; and he is to have a representative present during the tests who will be responsible for the handling of the packages containing the explosives until they are opened for testing.

(2) No one is to be present at or to participate in these tests except the necessary Government officers at the testing station, their assistants, and the representative of the manufacturer of the explosive to be tested.

(3) The tests will be made in the order of the receipt of the applications for them, provided the necessary quantity of the explosive is delivered at the plant by the time assigned, of which due notice will be given by the Geological Survey.

(4) Preference will be given to the testing of explosives that are now being manufactured and that are in that sense already on the market. No test will be made of any new explosive which is not now being manufactured and marketed, until all explosives now on the market that may be offered for test have been tested.

(5) A list of the explosives which pass certain requirements satisfactorily will be furnished to the State mine inspectors, and will be made public in such further manner as may be considered desirable.

A South African Colliery Accident

SPECIAL CORRESPONDENCE

The commission appointed by the Natal government to inquire into the cause of the explosion occurring in the Glencoe colliery early last year through which the lives of 70 persons were lost, has issued its report. The accident was due to an excessive charge of explosive, where the coal had been previously imperfectly blasted, creating a cavity in which gas accumulated. Serious blame is thrown upon the management for laxity of control and for failing to inspect the workings with proper frequency. Generally speaking, the coal mines of South Africa are remarkably free from danger of explosion, but the Glencoe mine is one calling for a special vigilance. One of the recommendations made is that in collieries where safety lamps are required, a new regulation should provide for the removal from a working place of all loose coal before drilling or coal-cutting is resumed.

Shape Brick and Methods of Calculating Requirements for Furnace Work *

BY ULRICH PETERS

A subject to which perhaps the least attention is paid in practical or theoretical discussions by engineers is that of the detailed construction and arrangement of bricks in furnaces, flues and foundations. Usually the mill bricklayer is supplied

obtainable grade of refractory material of moderate sizes are used and kept in stock. Suitable ready-made shapes have been in practical use for years for building up and repairing walls, ports and arches in the least time and with the least cutting and trimming of the bricks. Most of the geometrical brick shapes have in the interval progressed to certain standard dimensions, commonly called "stock shapes." Sizes vary more or less with the maker and the composition of the refractory material, which may have a different coefficient of expansion and con-

in. thick. As a stock shape it is commonly known as "9-in. straight," and is shown in Fig. 1. Evidently a greater number of combinations would result from adopting 2 1/4 in. in thickness instead of 2 1/2 in. The stretcher as well as the header courses, being then multiples of the individual dimensions, would match in all the various combinations for plain wall constructions. Firebrick, as well as the common red brick, are usually under-size and laid with very little clay mortar; if possible, rubbed close at the joints. Therefore little or no allowance is given

with no other information than an outline drawing of the furnace and flues he is about to build or rebuild. Detail questions generally come up when the roof arch or some other part of the furnace falls in—sometimes almost before the light of its fire is seen. The old-time method of chipping bricks to suitable shapes has been abandoned almost entirely by adopting shape bricks, and in order to obtain practical gas-tight walls of greater strength all necessary cutting to exact dimensions should be done by grinding. This gives beter results in quality of workmanship and economy of labor.

The building of the different parts of the furnace has an important bearing on its life. So-called shape bricks of the best

traction in the process of manufacture. So far only the natural tendency has been followed in the adoption of these standard forms, and no attempt seems to have been made to investigate for the best geometrical forms, or those giving the greatest number of combinations with the smallest number of different stock shapes. Complicated and irregular shapes are avoided as much as possible in furnace construction, as they are liable to cracks and distortions, and not being specially repressed, are not as strong as the sizes now in common use.

STANDARD SHAPES

The adopted standard mill size of a straight furnace brick in the United States measures 9 in. long, 4 1/2 in. wide and 2 1/2

for the vertical joints in the following standard thickness table:

Inches.	Ft. In.
4 bricks thick . . . 4 1/2	21 bricks thick . . . 2 0 1/2
1 brick thick . . . 0	3 bricks thick . . . 2 3
1 1/2 bricks thick . . . 1 3/4	3 1/2 bricks thick . . . 2 7 1/2
2 bricks thick . . . 1 1/2	4 bricks thick . . . 3 0
2 1/2 bricks thick . . . 2 1/2	etc.

For the horizontal joints of the courses of furnace masonry about 1/4 in. for mortar is allowed, so that the hights of brick walls are as follows:

Inches.	Inches.
1 course high . . . 2 1/2	5 courses high . . . 13 1/2
2 courses high . . . 5 1/2	6 courses high . . . 16
3 courses high . . . 8	9 courses high . . . 24
4 courses high . . . 10 1/2	etc.

The rules governing the construction of building masonry also apply in furnace work, i.e., the bricks should be in bond,

*From The Iron Age, Oct. 15, 1908.

and, if possible, none of the vertical joints of the alternate courses should meet. The latter rule is, however, not strictly observed in the bond usually employed in the furnace walls, in which for five to nine rows of alternate stretchers one row of header is used as face bond, Fig. 2. It takes much less time to build and practically answers the purpose as well as a better bond, being more or less temporary as compared with the life of furnaces in general. As a rule, all brickwork should be topped off with headers or a row lock, Fig. 3, to prevent the breaking out or falling out of bricks in the top layer.

The principal tapering shapes are further known as wedges, side arch and key bricks. In the wedge shape the sides taper toward the ends, while in side arches the sides taper toward the edges. Both shapes are extensively used in forming arches

sum of all the taper-brick angles used to form the circle will have to check up with the total angle of the circle. This gives us an easy method for figuring the proper angle of skewbacks, also a quick method by which to choose the taper and number of bricks to suit a certain skewback.

The accompanying table gives the number of bricks required to form circles of various diameters, and is intended for ready reference. For circles in general the number of taper bricks is derived from the equations below, wherein

r = the inner radius of circle in inches.

t = the thickness of circle in inches.

b = the number of adopted X shapes tapering

b to a inches.

y = the number of adopted Y shapes tapering

d to e inches.

The outer circumference is then

The figuring of arches having the span s , the rise r and the angle a of skewbacks can be conducted on one of two plans. The first is to make a test by the conditions involved in the equation

$$c = ax + ey,$$

which is to say, the length of the inside arc should equal the sum of the a and e lengths of the X and Y bricks used. Further, the sum of the angles of these shapes should equal twice the complementary angle of the skewbacks, i.e.:

$$\Sigma < (x + y) = 180 - 2a.$$

By a few trials it will be possible to arrive at figures checking with both equations.

The other plan is more direct and much similar to the former calculation of cir-

and circles. The key brick, whose edges taper toward the ends, are the shapes mainly employed for circular walls of coke ovens, lining of blast furnaces, etc. The accompanying table of taper bricks will be found convenient for practical reference. Other very important shapes are enumerated in a separate table.

RULES FOR THE CONSTRUCTION OF ARCHES AND CIRCLES

The construction of furnace arches according to best practice involves several problems. Arches and circles of various radii or diameters are built by proper combinations of the different taper bricks and the use of straights for enlarging. Evidently the sum of the included angle of all the single bricks equals the total angle of the arch between the skewbacks, as in Fig. 4. For a complete circle the total angle is naturally 360 deg., and the

$$C = 2\pi(t + r) = bx + dy,$$

and the inner circumference

$$c = 2\pi r = ax + ey.$$

Solving both equations for x , we have:

$$x = \frac{2\pi(ct - dr + er)}{eb - ad}.$$

Or

$$x = \frac{2\pi}{b} \frac{ct - bt + er}{c - a}$$

if d equals b , as is ordinarily the case.

For the number of Y shapes we have similarly:

$$y = \frac{2\pi(at - br + ar)}{ad - eb}$$

and

$$y = \frac{2\pi}{b} \frac{at - br + ar}{a - e}$$

if again d equals b .

cles. Here the length of the outer arc C and that of the inner arc c , previously calculated from tables, are substituted in the general equation

$$x = \frac{cC - dc}{eb - da}.$$

or for

$$y = \frac{aC - bc}{ad - be}.$$

It is much quicker and more accurate for the determination of the number and sizes of shapes required in an arch to use a little of the simple mathematics given than to rely only on a big scale layout, which according to my experience is seldom practically close enough.

After knowing the exact number of brick shapes required for an arch, it is necessary to distribute them in such a manner as to form a symmetrical arch,

Figs. 5, 6 and 7, also a strong arch. From the sketches of arches in Figs. 8 and 9 it is evident that even though both the same kind and number of shapes are used, the arch in Fig. 8 will be much stronger than the other. In distributing the shapes the tendency should be to throw those of greater taper toward the crown of the arch. Under any conditions a practical bricklayer will never use a greater number of straights than about 50 per cent. of the total required for an arch. Straights and taper brick should interchange as much as possible, and two straights should be avoided, because they often cause the easy slipping out of single bricks and the consequent failures of arches.

The most natural form of a roof and such arches as are not subjected to other

skewbacks, there are several points to consider. In the first place, having regard to scientific correctness, the skewback line should be radial. But this condition is not practicable where it is desirable to have only a limited number of stock shapes at hand. For radial skewbacks the ratio of the rise r to the span s will be, as in Fig. 10:

$$\frac{r}{s} = \frac{\sqrt{a^2 + b^2} - b}{2a}$$

For 45-deg. skewbacks $a = b$ and

$$\frac{r}{s} = 0.207.$$

The furnace builder will keep in mind,

$$H = \frac{W s}{8 r}$$

to

$$H r = \frac{W}{2} \times \frac{s}{4}.$$

And substituting for the weight

$$W = 128 \times s \times t,$$

if 128 is the weight of brick of 1 cu.ft.,

$$H = \frac{16 t s^2}{r},$$

in which t = thickness and r = rise of arch in inches and s = span in feet. It is easy to proportion from the above formulas the spacing of buckstaves and the size of tie rods.

“The Mineral Industry”

Readers of the JOURNAL are loyal constituents of “The Mineral Industry” and consequently are interested in the affairs of that annual publication, which has indeed come to be an institution rather than merely a publication. In the first place, we have pleasure in announcing that the response to the increase in the price of the volume, made last year, was such that the publication is to be continued. Its future is entirely in the hands of its friends.

This article is written to answer some inquiries as to how the work in connection with “The Mineral Industry” is done in so short a time. In outlining the magnitude of the work it is useful to quote from an editorial in the JOURNAL of Aug. 22, 1908, as follows:

“The average scientific or technical treatise is a work of about 400 pages, with about 400 words to the page. From the time when the manuscript is received from the author to the time of the publication of the finished volume, there is usually a period of six months. “The Mineral Industry” is a volume of upward of 1000 pages, and 500 words go to the page. Its publication is executed in the period of six to seven months, which includes not merely the putting of the book through the press, but also the preparation of the entire manuscript and the collection of its multitud statistics, the latter work alone involving the writing of thousands of letters and telegrams and the coordination and tabulation of the statistical reports.”

Considering merely the bulk of the products, “The Mineral Industry” is, therefore about three times the size of the average technical treatise.

The work of bringing out a volume of “The Mineral Industry” up to the time of furnishing the complete manuscript comprises the following:

1. Collection of statistics by direct reports from the producers and consumers. This involves sending out thousands of letters and handling the replies thereto. Comparatively few of the letters of re-

loads is the curve in which a perfectly flexible rope will hang, i.e., the catenary curve. Building a flat-roof arch the customary circular form of the false work is really not a mistake, for under the high temperature any arch will change its curvature and rise from the influence of the expansion of the bricks and tend to open up at the joints of the back, in many instances also causing the collapsing of a roof arch. Sand distributed on top serves here as the only effective means of keeping the arch bricks relatively in place, besides helping greatly to hold the heat in the furnace.

SKEWBACKS

With respect to the proper choice of

when not meeting the above conditions exactly, that a low skewback, shown to the left of Fig. 11, is better adapted for underground or loaded arches, such as flues, etc., while for arches not loaded, as in the case of roof arches, a slightly higher skewback, as shown on the right of Fig. 11, is to be recommended on account of its greater wedging action.

Roof arches exert a considerable thrust on the skewbacks, Fig. 12. This thrust per running foot of arch has two components, the horizontal thrust H and the vertical thrust P , which latter is simply equal to half the total weight of the roof arch. As seen in the figure, the horizontal thrust component is figured from the approximate relation

quests are printed circulars, the bulk of the letters being actually written. Many of the blanks are improperly filled out by the respondents and special correspondence must be undertaken to settle uncertainties. This work cannot well be inaugurated before Feb. 1, because at the offices of many companies reports from the mines and works are not received until about that time. We have found by experience that if requests for statistical reports be sent out earlier than they can command immediate reply, they are apt to be put aside and forgotten, which multiplies the correspondence. Even as it is, a great deal of special writing must be done to tardy producers, but we are pleased to say that the majority extend their interested coöperation and are prompt.

2. Collection of the statistics of foreign countries. In some cases these are also obtained by direct reports from the producers, but in general the official reports of the foreign government are used. It is desired always to give the statistics for the last calendar year. In some cases the foreign statisticians are two years behind, and then, of course, we must be content with the latest figures that they can give. Among the prompter, some of the official reports reach us by May, which is in ample time. We aim to publish "The Mineral Industry" as early in the year as possible. However, if we should publish it too early it would be inevitably deficient in information. We have decided that for going to press May 31 is the date that combines the maximum of usefulness with the maximum of promptness. In some cases, where the official reports are not going to be out until June, July or August, the foreign governments are so good as to give us advance copies of their reports in manuscript, thereby saving for us the time in passing through their printing offices, without anticipating their own publication. Of course, all of this also involves a great deal of correspondence.

3. The bulk of the commercial and industrial reviews are prepared in this office. Hundreds of letters have to be written to obtain the necessary information. Incidentally, we may remark that throughout the year the newspapers and technical exchanges are carefully scanned and clipped, and the clippings are filed under an adequate system for use at this time. In many cases the clippings are reliable; in other cases, they are merely suggestive and lead to correspondence for verification, etc.

4. The nature of the special technical articles, other than the regular reviews of progress in the arts, is determined and arrangements are made with the desired contributors. Of course, this is generally done previous to Feb. 1. But after that date there is inevitably an extensive correspondence with the contributors, of whom the number to Vol. XV was 105. Besides the work of the outside contributors, a large part of the reviews are written by

our regular staff. The matters of editing the MSS., reading the proofs, coordinating the whole, etc., including keeping track of the work (not the least of the details) we shall not go into here.

We come now to the matter of putting the book through the press. We plan a volume of about 1000 pages, of which about 100 are devoted to the foreign statistics and general matter that may here be dismissed from consideration. This leaves about 900 pages of straight text.

This determination of size is not based upon any mechanical reasons (although it is desirable to have a book that will be mailable without having to use unpleasantly thin paper); it is the maximum that the present editor can supervise. We send the first "copy" to the printer on Feb. 15, and expect to have the last piece of "copy" in type on May 31. This means doing the whole composition in 15 weeks, or at an average rate of 60 pages per week, which is conformed to as nearly as possible. The printer can do the type-setting much faster than 60 pages per week; indeed it is difficult to prevent him from accumulating "copy" until he can run off 200 pages in a few days. The controlling factor here is that we cannot revise proofs, etc., faster than 60 pages per week.

We cannot always supply required statistics when the "copy" goes to the printer. Perhaps the figures will be filled in on the galley proof; perhaps not until we receive the proof in pages; invariably a large number of pages are being held on May 31, awaiting figures. If the manuscripts were held back until complete in all respects, the book would be a year "in the pickle."

Another factor that contributes to promptness is the preparation of the manuscript, and composition of the same, so far as possible in the alphabetical order of the chapters. The result of this is that the chapters on aluminum and antimony may be printed and in the bindery, awaiting the arrival of the last sheets, before zinc has been completed.

Thus it will be seen that every week after Feb. 22 the available space is diminished by 60 pages, and that if we do not receive the several manuscripts at the required times we shall be to some extent delayed; also if manuscripts come in late and greatly exceed the estimate of their probable length, we shall also be in trouble. Of course, we can never operate strictly according to schedule. We have always to leave gaps for some belated articles. (In that case the article must of necessity be cut down to fit the gap; we never leave too big a gap.) But the fewer gaps we have to leave, the smoother is the progress of the book.

We aim to have everything in type on May 31, in which event the book will be out before the end of July, something like two months being required to revise the last proofs, print, and bind. If every-

thing were in the best possible shape on May 31, it might be possible to bring out the book in the first week of July, which some year we hope to accomplish.

Rope Driving

BY SYDNEY F. WALKER*

Rope driving is arranged in two ways. In America the method preferred is to carry a single rope from pulley to pulley as many times as there are grooves in the pulleys, the ends being then spliced together so as to form one endless rope. In the United Kingdom, the method preferred is to have as many endless ropes as there are grooves in the pulleys. In my opinion, the American method has the great advantage that all parts of the rope take their share of the strain, and therefore, as compared with the English method, a smaller number of turns should be able to do the work. In the English method it is supposed that each rope takes its share of the work, but in practice it is always found that a portion of the ropes are tight, doing the work, and the remainder slack. What happens is that the ropes which are doing the work at any instant become stretched, and gradually fall out of service; the other ropes then gradually take the work up, then they become stretched, and fall out of service, and so on. But the practical point appears to be, that twice or three times the number of ropes that could perform the drive must be present. It is claimed for the English method that it is more easily cleared, if a rope breaks, for with the American method, if the rope breaks, there is a very much longer length of rope to give trouble.

Transvaal Gold

The gold production of the Transvaal in January is reported by cable at 615,113 oz. fine, or \$127,143,86. The output was 45,487 oz. less than in December, but the production of that month was swelled by the inclusion of reserve gold and other additions. A fairer comparison is with November, and the January production exceeded that of November by 740 oz. It was greater than that of January, 1908, by 54,784 oz. During the month there was some interruption of production by the floods on the Rand, which interfered with operation of mines and mills.

The Robinson mine in the Transvaal reports for 1908 a total profit of \$5,500,000 from its mill of 220 stamps

*Consulting engineer, Bloomfield Crescent, Bath, England.

Glory-Hole Mining at DeLamar, Nevada

The Material Is Drawn from an Old Widened Ore Chute, the Total Cost of Extraction Being Less Than Thirty-four Cents per Ton

B Y W . R . W A R D N E R *

The De Lamar mines are situated 30 miles west of Caliente, Nev., a division point on the Salt Lake route, and have been worked for the last 14 years. The Bamberger De Lamar Gold Mines Company, controlled by Salt Lake and New York men, has operated the property for the last six years. The company owns its own electric power plant, situated on the railroad at Stine. Utah coal is used as fuel and the power is transmitted to the mine 13 miles away. There are 14 miles of pipe lines and four pumping stations to supply water to the town and works. All supplies for the mine are hauled from Caliente over a very fair wagon road at a cost of 55c. per hundredweight.

sets, for the workings are so extensive that it is impossible to make an intelligible representation.

Originally the present glory hole was a prospect raise from No. 10 level to the surface, which was later used as a mill hole and called rock chute No. 5. By years of use the chute was cut out until it was in places more than 50 ft. across. As will be seen on the sketch plan the chute lies between the southeast and southwest veins. Owing to its unusual size it was a constant menace in the extraction of the surrounding orebodies by the square-sets system. In fact stoping had been carried beyond a point of safety and it would not have been possible to

broken down; it is evident that gravity alone will break most of the ground for some time to come. As shown in the drawings the ore will slip away from the gouges; since the formation back of them is very hard it does not slab off to any great extent. In fact there are perpendicular walls of quartzite 200 ft. high in the open-cut workings that have been standing unsupported for several years.

The broken ore varies in size from dust to boulders of very hard quartz, many of them weighing several hundred tons. Up to date practically the only expense for breaking ground has been in handling these boulders. There is considerable waste in the ore, most of it being gouge

GLORY-HOLE FROM SURFACE

DE LAMAR, NEV., SHOWING TOP OF GLORY HOLE

The country is quartzite dipping to the east at an angle of 15 deg. from the horizontal. The ore occurs in relation to a system of north and south gouges and east and west cross dikes. The ore deposits and peculiarities of mineralization are very large subjects in themselves and will not be considered in this article.

CONDITION OF THE WORKINGS

The accompanying sketch of the glory-hole ore zone shows a part of the vein system on the plane of Level No. 6. The sections A-A and B-B give a good idea of the way the ore lies about the glory hole. In these drawings no effort is made to show the areas already stoped by square

take out much more ground by that method.

Assuming a workable area by glory hole down to the level No. 8, there remained in these two orebodies alone something like 250,000 tons of ore, of proved value, in pillars and backs, to say nothing of stope fillings of ore from previous years operations which could not be worked profitably when a high mill heading was maintained. To obtain this tonnage cheaply and safely was the engineering problem that confronted the management.

METHOD OF OPERATION

The commencement of glory-hole operations was the caving of the stopes around chute No. 5 into the mill hole. At this time there was about 50,000 tons of rock

and dike matter with some country rock. It has been found more economical to neglect the small waste entirely, and the only sorting that is done is to pick out the larger pieces. By so doing the dirt is handled quickly and at a low cost.

On account of the very large tonnage of broken ore contained in the glory hole—20,000 tons most of the time—it is advisable to draw the ore in such a manner that the grade will average fairly high, and with this end in view it is customary to attack the pile at any convenient entry in the upper levels, being governed by the position of the better ore. For instance, if the rock in the lower part of the hole is of low grade, and there is a cave of better ore on top, instead of waiting for this to be drawn down to the level No. 10,

*Mining engineer, Hollywood, Cal.

as large a part of the tonnage as necessary is tapped from entries on the upper levels. In this way a steady output is maintained without any material sacrifice of grade.

HANDLING MATERIAL

The sketches showing the sorting chambers and entries on level No. 10 to give a fairly clear idea of the arrangements for handling and sorting this material in the most economical manner. The broken rock is drawn down upon 10x12-ft. shoveling plats, the larger waste is thrown into the waste pocket and the ore into the ore pocket. There are four of these chambers. It often happens that a large boulder comes down and completely blocks a chamber; this must be broken up, the other chambers being used in the meantime in making the required output. The train draws the pockets as needed, usually twice a day. The method of handling the rock on the upper level entries is about the same with the exception that the waste

SECTION A-A

SKETCH OF ORE ZONE

SECTION B-B

must be laid aside, the ore loaded into smaller cars and run to the nearest mill hole, and the waste to the waste hole.

The danger is small, for about all the men have to do is to protect themselves from a run of rock in the breast of the room. Most of the time they are working under cover. There is some risk in blasting the boulders when a chamber is blocked; but for an intelligent miner accustomed to this work the danger is not great.

COSTS

The accompanying tables of costs are for five months' operations. During this time the glory-hole ore amounted to 58 per cent. of the mill tonnage; the other 42 per cent. was obtained from the stopes. 86 per cent. from square-set stopes, 6 per cent. from stull stopes, 4 per cent. from fillings, and 4 per cent. from development. For this period the mill monthly average was 9800 tons.

COST OF PRODUCING GLORY-HOLE ORE (28,400 Tons).

	Amount.	Per Ton.
Labor (handling and sorting)	\$7,958	\$0.280
Labor (hauling to mill)	1,137	0.040
Powder, fuse and caps	258	0.009
Candles	191	0.007
Hardware and tools	13	0.000
Total	\$9,556	\$0.336

CONTINGENT EXPENSES OF MINE (48,900 Tons).

	Amount.	Per Ton.
Foreman and shiftbosses	\$4,499	\$0.092
Tool dressing and nipping	5,281	0.108
Track and pipe work	1,027	0.021
Hoisting (men, timbers and tools)	1,858	0.038
Compressed air	4,401	0.090
Assays	2,103	0.043
Surveying	334	0.015
Total	\$19,903	\$0.407

COMPARISON OF COSTS PER TON.

	Stopes.	Glory Hole.	Run of Mine.
Cost of producing	\$1.909	\$0.336	\$0.993
Contingent expenses	0.407	0.407	0.407
Total mine cost	\$2.316	\$0.743	\$1.403

From these tables it appears that there is a margin of \$1.57 per ton in favor of the glory-hole product, a large difference in itself. The system allows a profit on exceedingly low-grade material. It is evident that even should the value of the glory-hole ore fall so low that there would actually be no profit, so long as there is no loss, it would pay to continue operations by this method, since the cost of producing the run-of-mine ore is so greatly reduced that it is possible to make the maximum profit from the better-grade ores such as the mine affords.

COST OF PRODUCING STOPE ORE (20,500 Tons).

	Amount.	Per Ton.
ORE BREAKING:		
Labor	\$12,435	\$0.606
Powder, fuse and caps	3,144	0.153
Candles	332	0.016
Hardware and tools	130	0.007
Total	\$16,041	\$0.782
TIMBERING:		
Labor	\$3,840	\$0.188
Lumber (plank)	\$4,649.94	
Round timber 30c	532.20	
Pole lagging 20c	52.40	
	\$5,235	\$0.255
Operating sawmill	305	0.015
Hardware and tools	230	0.011
Total	\$9,610	\$0.469
HAULING AND MUCKING:		
Labor (including haulage to mill)	\$12,217	\$0.596
Operating electric haulage system	876	0.043
Candles	335	0.016
Hardware and tools	68	0.003
Total	\$13,485	\$0.658
Grand total	\$39,136	\$1.900

C. D. Leslie, general manager for the Simmer & Jack Proprietary Mines, in the company report for the year ending June 30, 1908, states that, while the cost of recruiting and repatriating the Chinese laborers has been great, the remarkably high standard of efficiency attained by them proved a valuable object lesson to the native "boys," and he attributes the increased efficiency of the Kafir "boys" in a great measure to the example of the Chinese. While the Simmer & Jack company employs more Chinese than any other mining company on the Rand, still by reorganizing the work to the great advantage the number of Chinese employed was gradually reduced during the year without any diminution in profits.

It is not always an advantage to connect several mines, for often the ventilation becomes poorer than before, since the farther the air travels through mine workings the more it becomes vitiated.

Mining in Spain

A recent consular report gives figures for the mineral production of Spain during recent years. With the exception of coal the statistics are those of export.

In metric tons the exports of iron ore and pyrites in 1907 were: 9,966,135; in 1906, 10,349,619; in 1905, 9,349,869. Nearly half this tonnage was exported from Bilbao, Santander and Cartagena handling nearly a million tons each. Spanish iron ores are of unusually high grade, those from the Calasparra mines, in Murcia province, averaging a little above 60 per cent. metal with low sulphur and phosphorus. The Bilbao district is declining, and in 30 years will probably be worked out. From the mines of Asturias, which last year produced about 60,000 tons, an increased output is expected; and when the port of Musel is completed, five years hence, it should be possible to ship up-

790,177 tons of ore, and about 200,000 tons of steel was made. The Sociedad de Altos Hornos de Vizcaya and the Sociedad Metallurgica Duro-Felguera are the chief works.

With 185,000 tons, Spain reached the second place among the world's producers of lead last year. Lead is mined in the southern provinces of Jaen, Murcia and Almeria, the chief center being Linares. But much business is done around Cartagena, where the Linares, Mazarron and Gurrucha ores are smelted. Lead exports for 1907 were 170,131 tons.

The Almaden mines increased their output of quicksilver in 1907 to about normal, i.e., 1500 tons, the average grade of cinnabar treated being 9.6 per cent. A recent commission reported that there were 400,000 tons of mineral above the twelfth level, and twice that amount below, and considered that the Almaden was well able to control the market.

The export statistics for 1907 of other

ments for the payment by mine-owners of lump sums. Foreign mining companies in Spain are likely to be seriously affected by the proposed measures restricting mining work to native engineers.

Moderate-Pressure Air Compressors

SPECIAL CORRESPONDENCE

Owing to the great demand for moderate-pressure air compressors for industrial air blast and exhaust service the General Electric Company has designed a centrifugal type of fan and is now prepared to furnish a line of standard centrifugal air compressors with pressures rated from 0.98 to 4 lb. per sq.in. and in capacities from 750 to 10,000 cu.ft. of free air per minute.

Sorting Chambers
and Entries
10 Level

ARRANGEMENT FOR HANDLING AND SORTING MATERIAL ON NO. 10 LEVEL

ward of 200,000 tons. There are other large deposits in Burgos province and in the Sierra Menara, but their situation for foreign transport is bad.

Of coal Spain in 1906 produced 3,095,043 tons; almost the same amount in 1905. In this field the English industry predominates, the imports last year being 2,544,466 tons.

Spain does a considerable business in tin plate in connection with the Gallician sardine-canning industry. About 20,000 tons is the annual consumption. The imports from England last year were 4475 tons, the rest came from the Hornos, Basconia and Lugones copper works. The product is said to be inferior to the Welsh plate. A duty of 140 *pesetas* per ton protects the industry. In 1907, 254 tons were exported, as against 94 in 1906, and 79 in 1905.

The north of Spain being productive of rich iron ores and fuel, the iron and steel business has grown important. In 1906 379,241 tons of pig were produced from

mineral products were, in tons, as follows: Calamine, 33,882; antimony, 362; copper, 1,239,874; manganese, 67,997; zinc 1391; blende, 120,184.

The 1907 figures for copper show an advance over those of 1905 of about 25 per cent.

Petroleum was worked in Cadiz province during the year, and some prospecting was done elsewhere.

The production of sulphur for 18 months ending December, 1907, was 6000 tons, a reduced output due to the flooding of the mines.

In Alicante the Torreveja salt mines produced nearly 140,000 tons; the salt pans of Cadiz about 250,000.

An increasing emigration due to low rates of wages has led the government to pass a restrictive emigration law, which, it is hoped, will stop the drain.

There is a 3 per cent. tax on the gross output of all mines, and the authorities have experienced considerable difficulty in collecting it. They are making experi-

In appearance and in operation this type is similar to the well known centrifugal pump for it consists of a rotating impeller surrounded by a suitable casing with an intake opening at the center and a discharge opening at the circumference. For driving these blowers hydraulic turbines or directly connected motors using either alternating or continuous current are used. The pressure in the mains leading from the compressor is entirely free from pulsation and practically constant for all volumes within the rated capacity of the compressor. Contrary to the results obtainable with positive pressure blowers, the power required to drive these so-called centrifugal compressors is said to vary approximately with the volume of air delivered when operating at a constant speed. This fact gives a greater flexibility, and improved economy to the centrifugal type where variable loads are required, satisfactory efficiency being obtained between the limits of 25 and 125 per cent. of the rated load.

Electric Recording Apparatus for Mine Watchmen

By CARL L. C. FICHEL*

An electric system for recording the movements of watchmen is installed and in operation at one of the deep shafts of the Calumet & Hecla mine. The apparatus is operated by means of electromagnet, current being obtained from storage batteries at 30 volts and a flow of 75 m.-amp. In the shaft there are at present 49 stations, representing the beat of seven watchmen and necessitating the running of seven complete circuits. All wires leading down the shaft are encased in a $1\frac{1}{2}$ -in. pipe. At each level, or station a junction box is placed, with a

switchboard. The storage batteries are composed of 15 cells each, each cell containing nine 6x8-in. plates inclosed in a glass jar. The motor-generator set consists of a three-phase, 440-volt induction motor, direct connected to a 3-kw., 30-volt direct current generator.

The switchboard panel for controlling the charging current has a voltmeter and an ammeter so connected that a reading on either set of storage batteries or the generator may be taken, and the voltmeter can also be used to get a ground-reading on any of the underground circuits. This switchboard also contains controlling switches, a rheostat and two I. T. E. circuit breakers.

The time element of the recording apparatus consists of a clock operated by means of heavy weights. Geared to this

through the wheel *A*, this wheel or any part of the mechanism being one side and the brush *B* which is insulated from it, the other. By turning the key one turn the spring is tightened, which then gradually works back, causing the wheel *A* to make one complete revolution and breaking the circuit the same number of times as there are notches in this wheel. The time of making this revolution is controlled by the pendulum *C*.

After the watchman has turned his key one complete revolution, the movements of the mechanism within the box are beyond his control; the winding device consists of a ratchet and arm placed on the under side of the box cover. The spring does not begin to actuate the movements until the shaft upon which it is fastened is turned to a point where it catches, by

STATION BOX MECHANISM

$\frac{1}{2}$ -in. pipe tap leading off to the station box and in which the electrical connections are made in series. The station boxes are of cast iron, and contain a clock-like mechanism mounted on a porcelain base and actuated by means of a spiral spring. These boxes are constructed so as to be as nearly moisture proof as possible, but the extreme variations of temperature caused considerable moisture to collect within the boxes and caused the steel parts to rust. This one disadvantage was overcome by filling the chamber with oil.

SURFACE EQUIPMENT.

Besides the recording apparatus with its switchboard, the surface equipment includes two sets of portable storage batteries and a motor-generator set for charging, together with the necessary

*Calumet, Mich.

CLOCK CIRCUIT

clock and in such a ratio as to make one complete revolution in eight hours, is a brass roller, 30 in. long and 20 in. in circumference; on this roller is fastened the log, or sheet, upon which the numbers corresponding to the underground stations are stamped. This log is a record for 24 hours, from 6 p.m. to 6 p.m. and is divided into spaces, each representing 10 minutes. It takes records of the movements of 30 watchmen.

The electrical arrangement consists of two independent circuits; the one leading from the apparatus to the underground boxes is a closed circuit and the one contained within the apparatus an open circuit.

METHOD OF OPERATION.

By referring to the accompanying sketch of the station box mechanism it will be seen that the circuit is opened and closed

means of a dog, the drive gear *D*, but simultaneously the arm is released from the ratchet, and any further turning of the key cannot hinder the action of the spring until the normal position has been resumed and the number of the station recorded.

The opening and closing of the circuit causes the arm *A*, which is held against the tension of the spring *B* by the pull of the magnets to operate back and forth and consequently to move the type wheel forward a number of spaces corresponding to the number of breaks. The instant this circuit is opened and the magnets release the catch *D* it drops, allowing the projecting point of the arm to fall on the ribbed roller. This roller is connected by means of a sprocket and chain to the clock and allows the arm to work slowly down, and its weight to bring the two points of the local, or clock circuit to-

gether; it takes about 30 sec. to accomplish this, which gives the underground box ample time to have returned to normal position and to close the circuit.

The closing of the local circuit energizes the solenoid *F*, which causes the type wheel to be brought down with great force upon the log, thereby stamping, with the aid of an inked ribbon, the number of the station. This same movement in conjunction with the adjustable rod closes the local circuit and again brings it under the control of the underground circuit. The lever is returned to its normal position by the action of the spring and the dashpot placed above the solenoid, the plunger of which is an extension of the solenoid plunger. This is done slowly allowing time for the type wheel to be returned to its starting position by the pull of the spring placed beneath the lever.

The switchboard is composed of three panels of white marble. Mounted upon it are lightning arresters, current indicators, ammeter plugs and push-button connections for ground readings on either side of the line. There are also the double set of knife switches for controlling the two circuits.

The records made by this recording apparatus show at a glance the time at a station and also the time intervening between stations.

The Opasatika Lake District, Province of Quebec

By FRITZ CIRKEL*

A number of discoveries have been made on the stretch of lakes extending from the lower arm of Wendigo lake, 35 miles north of Cobalt northeast toward Opasatika lake, on the Quebec side of the line; and although their proper exploitation seems to be handicapped at present by the difficult access, they are important for the fact that they demonstrate the extension of the mineralized belt into the province of Quebec.

The route of travel begins at Heaslip Station, about 30 miles north of Cobalt; a stage drive over a good government road leads through Toms-Town to Wilsons Landing on the western shore of Wendigo lake, a distance of $9\frac{1}{2}$ miles. Here the canoe route commences, and the trip leading through a whole stretch of lakes, ponds and rapids in high water, is somewhat hazardous. The distance from Wilsons Landing to Opasatika lake by this canoe route is about 30 miles; in low water 15 portages have to be made of which the longest is about half a mile. Under ordinary lake-level conditions these 15 portages may perhaps be reduced to about eight or nine.

Physically the country traversed is one

of the roughest; low hills change with mountainous ranges, rising abruptly in cliffs over the water's edge. No agricultural land could be seen along the whole canoe route; the country is of uneven, rocky nature, and is covered almost wholly with original forests, or with a second growth of timber. Toward lake Opasatika, on Birch lake and Green lake, high, straight cliffs partly form the lake shores, and the various colors of moss covering these rocks, impart to the whole a beauty of its own.

A year and a half ago Wendigo and Raven lakes were the scene of extensive travel to Larder lake, which was reached by trail from the upper arm of Raven lake.

THE ROCKS
The rocks along the route belong to

OPASATIKA LAKE DISTRICT, QUEBEC

different geologic horizons; no special study has as yet been made of them. Along Wendigo lake the rocks seem to consist mostly of a gray-greenish conglomerate, approximately the same conglomerate as that found around Cobalt. The conglomerate is cut by dioritic and basaltic rocks, and some discoveries of cobalt have already been made in this series.

Several years ago almost the whole shore of Wendigo lake was staked, but subsequent prospecting work showed, save for a few discoveries, that that part of the country is not bountiful in minerals. Arsenical pyrites is frequently found in the conglomerate and in one place, where more work has been done, the ore occurs in small veinlets or pockets irregularly distributed through the rock and not confined to what may be called a vein or

ore lode. Whether this arsenical pyrite carries any gold I am not able to say, but the work which consisted of a shallow cut into the hillside was subsequently abandoned. Several discoveries of cobalt bloom were made, some of them carrying silver, but exact and reliable data could not be obtained.

The most important discoveries have undoubtedly been made on the shores of Turtle lake, Moose lake and Mud lake, west of lake Opasatika. Access to these locations is difficult.

Around Turtle lake the rocks consist of a greenish slate, for the most part, with distinct bedding planes; the strike varies from northeast to strictly east-west, while the dip varies from the horizontal to almost vertical. These rocks are fine-grained, and represent probably the alteration product of gabbro and dolerite. They vary in color from pale gray-green through yellowish green to dark green; they are generally rather soft rocks, yielding to the scratch of the knife.

MINERALIZED VEIN

Fissures are numerous and are for the greatest part filled with a milkwhite quartz, carrying minute particles of iron pyrites or chalcocopyrite. These quartz veins either occur as a series of parallel stringers from $\frac{1}{2}$ in. up to 12 in. in thickness, or they occur as regular lodes of solid quartz, measuring all the way from 1 ft. to 70 ft. in thickness. Their general or approximate strike is east-west; their dip almost vertical. Almost all of the quartz lodes observed are metalliferous. The most frequent constituent is copper pyrites and in a less degree iron pyrite, the latter imparting to the quartz a rusty color wherever it occurs.

Altogether seven vein locations have been made, but several of the latter, according to survey, have been made in the same ore lode, and the number of metalliferous quartz veins may be reduced to four. The most important of these veins is one located on the north shore of Turtle lake. This vein strikes northeast 80 deg.; it dips almost vertically and consists of a rusty quartz carrying rich disseminations of copper pyrites, with green and blue carbonates interspersed; the lode is at some places 2 ft., in others 3, 5, or 10 ft., and in others it is split up into several separate quartz lodes, without, however, losing its ore.

The assay value ranges between 4.5 and 6.5 per cent. copper; in some places assays as high as 10 per cent. were obtained. Most of the accompanying country rock is impregnated with the mineral, and there is reason to believe that in actual mining operations, instead of a strictly silicious ore a semi-silicious copper ore may be produced. This ore lode has not been followed far inland, but judging from the strong character of the vein there is some ground for the assumption that its horizontal expansion is large.

*Mining engineer, Montreal, Canada.

All these locations were made close to the shore; no attempt has yet been made to follow farther inland; in fact not one discovery has been made farther than about 1000 ft. from shore.

TOWARD LAKE OPASATIKA

Proceeding from the Turtle lake region along the chain of lakes toward Lake Opasatika the formation changes entirely. Instead of the greenish varieties of rock we meet fine-grained grayish quartzites, graywacke, granitoid and purely feldspathic rocks. Reddish granites are frequent and form for the most part the steep shores of several of the smaller lakes. In the vicinity of Moose lake and Mud lake quartz lodes of considerable extent have been explored; they range in width from 10 to 70 ft., the strike being mostly east-west, or nearly so. They are not auriferous, but they carry fine disseminations of copper pyrites; the quartz lodes are divided by planes parallel to the walls into several parts, each of which carries a certain percentage of the ore. One part, say, of 3 ft. may contain an average of 3 per cent. of copper, while the next division may not carry more than $1\frac{1}{2}$ per cent. Exploration on these large quartz veins has not been carried far enough to allow of an average assay being taken, but from present indications it appears that a good part of some of these large veins may carry copper ore above the working limit.

The country, however, is not conveniently accessible for actual operations, and here, too, the lack of transportation facilities will prevent mining for some time to come.

All the discoveries along the stretch of lakes toward Lake Opasatika go to show that this country is not so devoid of mineral deposits as originally supposed, and it is likely that in the course of time additional discoveries may be made, which may induce the Quebec government to do something in the way of furnishing proper transportation facilities.

A Novel Stadia Rod

By J. H. GRANBERY*

In preliminary surveys and often in more accurate work, the use of stadia measurements is rapidly increasing. This is primarily due to the convenience of such methods, as well as to the saving of time resulting; such measurements compare favorably for accuracy with ordinary chaining, and bring the responsibility for the work directly to the instrumentman who is generally more accurate and careful than the subordinate chainmen. Stadia work has, however, been limited to sights of 1000 ft. or less. Beyond this distance

most of the characters upon the ordinary stadia rod are so indistinct that the rod cannot be read; at even less distances the red characters appear black, and the figures used to denote the unit divisions are confusing and often illegible.

In surveying marshy islands on the Georgia coast, the interior of which was often inaccessible, a system of primary triangulation was used for the establishment of points from which measurements might be taken and referred to the base lines used in the triangulation system.

urement, by a single sight, of distances as great as 3800 to 4400 ft. The rod has no figures; the divisions being indicated by characters of varying form, but each foot of division bears the same characters, in the same relative position, as every other foot. In practice it is found easier to count the divisions than to decipher a printed figure; indeed, counting divisions is itself dispensed with after a short use of the rod, as the location of signs, rather than the counted divisions guides the instrumentman, in much the same manner that time is usually read by the position of the hands on the clock face rather than by reference to the numerals. Consequently, readings may be made with great rapidity.

DIVISIONS

The rod is divided as shown in Fig. 1, the T-shaped characters being used for the major divisions; the stem of the T is 0.1 ft. in vertical width, and the arms extend 0.1 ft. beyond the stem. Each of the minor divisions is also 0.1 ft. in vertical width, and reference to the figure will show that by the grouping adopted every tenth of a foot is marked by the edge of a solid black figure so that the rod is easily read at a considerable distance.

Subdivisions into 0.01 ft. are made by the small forms or characters shown in Fig. 2; each of these is so formed that the division is at the edge of a solid black figure, in the same manner as provided for the tenths divisions. By making the divisions as shown it is seen that reading to half tenths, or to fiftieths, is facilitated; hundredths are also equally prominent and read with the same degree of ease. The fact that every hundredth is represented by a different combination of length, or position, of the edge of the character makes the reading as plain, after practice, as if the numeral itself were seen. By placing the characters representing feet and tenths at opposite edges of the face of the rod for alternate feet the reading may also be facilitated, as all the even feet divisions are then at one side and all the odd feet divisions are at the other side. This has been found unnecessary in practice, however, as the characters are so clear and distinct that mistakes of observation are rarely due to reading.

In making the sights referred to, a rod 23 ft. long was used; it was made of two long strips of light, dry wood, secured to each other in the form of a T so as to prevent warping and twisting. The rod was handled by one man, and the readings were made first between the lower stadia wire and the horizontal cross-hair, and then (without removing the eye from the telescope of the transit) between the cross-hair and the upper stadia wire. The mean of the two readings was used—with an instrument in perfect adjustment a single reading, however, would suffice.

FIG. 1

FIG. 2

The base lines were chained with great accuracy in every instance, but the character of the shore was prohibitive of meandering, or of instrumental determination using only one instrument, unless stadia measurements were resorted to. The ordinary stadia rod was tried, but, except in a limited number of instances, the length of sight required was too great for its use. Accordingly, I designed for the work a stadia rod which has several novel features.

A ROD WITHOUT FIGURES

The method of division is the striking feature of the rod. It was developed after trial of various forms and has proved of accurate service in the meas-

*Consulting civil engineer, 20 Broad street, New York City.

Sand Boils

By J. J. FRED BRAND*

CONTROL OF FURNACE

All the constituents of the pig iron (carbon excepted) were specified, but in the absence of a laboratory it was necessary to judge the progress of the metal during the oxidation period, and the condition of the scrap, by test plugs which measured 1x1x6 in., which were cast in sand. Those taken by the melter on the platform were allowed to remain in the sand for two minutes before drawing, when they were slowly cooled by quenching in water. The first test was taken immediately after the metal was melted; the remaining tests were taken at intervals of 10 to 20 minutes. Those taken at the spout at certain intervals during the pour were allowed to cool in the sand. Thus we were able to judge within close limits the percentage of silicon in the scrap.

According to the memoranda there was but little difference in the appearance of the scrap which was charged into the above heats, but the melter's first tests show that melt No. 204 contained a little less silicon than melt No. 203 at the time charges were melted.

Those first heats were dreaded, except when some new remedy was to be tried; we were many times led to believe that a remedy had been found, only to find out sooner or later that another cause contributed to the success of that particular heat.

The general opinion was that the bottom, not being thoroughly fused, would peel off and rise to the surface of the metal, thus causing the slag to become acid from which silicon would be reduced and absorbed by the metal. In accordance with the above opinion special efforts were made to fuse the bottom thoroughly before charging.

The best grade of quartz sand was considered too refractory to be used alone; therefore, various proportions ranging from a few shovelfuls to half of the batch of a poorer grade of silica were added; at other times various proportions of fireclay or firebrick dust were added or sprinkled over the top. Crushed slag was always thrown in just before the metal was charged, that is, after the bottom had been burned well, which was (unless the freman happened to be irregular) heated intensely.

Many trials, covering a period of two years or more, were made to solve the problem along this line, and all failed. In view of the past failures and the following evidence, the writer had reasons to believe that the above conclusion regarding the reduction of the silica in the slag was wrong.

The slag from a first melt differed from the slags of the succeeding melts in that it was yellow and more basic than the black slags of the succeeding melts, as the following analysis will show:

No. 1 is a yellow slag from a first melt

on a new bottom, while No. 2 is a black slag of the succeeding melts.

	No. 1, Per Cent.	No. 2, Per Cent.
SiO ₂	37.05	51.52
Al ₂ O ₃	16.30	18.10
FeO	3.60	22.00
MnO	1.65	1.85
CaO	32.11	3.81
Fl.	8.33	trace

It is highly improbable that silicon would be reduced from No. 1 slag, when no irregularities were experienced from No. 2 slag. It is also reasonable to suppose that if the silicon came from the slag, a test taken from the metal nearest the slag should give a fracture as dark as one taken after rabbling. No doubt existed in my mind at any time that the reduced silicon did not come from an acid slag, but that it came from the sides and bottom of the hearth.

There was every reason to believe that such was the case. Take, for example, the analogous killing or dead-melting stage in crucible steel manufacture, during which silicon is reduced from the walls of the crucible; provided, that the proper percentage of silica is present in the walls of the crucible, and sufficient carbon in the iron, with the required high temperature. It is self-evident that this latter condition is present in both iron and crucible, as externally applied heat must pass through the crucible walls before the whole is raised to a casting temperature.

In malleable practice both the carbon and silica are necessarily present in such amounts as would favor the reduction, but unless the silica hearth is of a proper temperature it cannot take place. In the attempt to keep the hearth from peeling off by the excessive heating, the conditions were made ideal for the reduction of silica from it.

Finally an opportunity was taken to put the theory to test and a succeeding bottom of the best grade of silica was put in, and heated only to redness; a barrow of crushed slag was then scattered over it and allowed to melt. A mixture of the same iron which gave good results on the previous old bottom was charged, but was melted, hot, and ready to tap in 18 minutes less time than had been required for the preceding charge.

The result of this single experiment, however, was not accepted as conclusive evidence that the theory was correct; we made further trials which were satisfactory, and we have every reason to believe that the cause of the phenomena has been discovered, as no more trouble is being experienced from "sand boils."

Shipments of tin from the Straits Settlements to the United States and Europe in January were 5733 long tons; an increase of 500 tons over January, 1908.

There seems to be but little published information on the subject of sand boils. An explanation of their causes, and a method of preventing them, which works well in practice, came only after much thought and many experiments.

The furnace at which the experiments were conducted is of the air, or reverberatory type, having a capacity of 10 tons. The blast is supplied by a fan blower through a 9-in. pipe which leads to the ash pit. A 70-ft. stack, 48 in. in diameter carries off the products of combustion.

The hearth, which measures 12x0.5 ft., is separated from the firebox by a 16-in. bridgewall, built 22 in. higher than the grate bars; the opposite end of the hearth gradually slopes into the neck leading to the stack. The silica bottom is put in when the furnace is cold and is heated before charging the metal. The life of the bottom is 6 to 15 heats, before it is necessary to renew it. The first charge on new bottoms usually gave trouble. Charges of a certain analysis, melted on an old bottom, were ready to tap at the scheduled time, while another charge of the same mixture melted on a new bottom, would remain in the furnace anywhere from one to four or more hours longer.

The following record of two such heats taken from my memoranda will serve as an illustration: The first is the record of heat No. 203, weight 5850 lb., and was the last charge melted on an old bottom. The second is the record of heat No. 204, weight 5875 lb., the first charge melted on a new bottom.

No. 1: 585 lb. of pig containing 1.58 per cent. Si; 585 lb., 1.31 per cent. Si; 585 lb., 2.21 per cent. Si; 1170 lb., 1.51 per cent. Si; and 2925 lb. scrap containing, approximately, 0.60 per cent. Si. The scrap and pig charged at 9:32 o'clock, melted in 1 hr. and 43 min., and was tapped 59 min. later. The first test was only slightly turned; this heat was tapped when the test gave a clear fracture. Metal ran well.

No. 2: 585 lb. of pig containing 1.58 per cent. Si; 585 lb., 1.31 per cent. Si; 585 lb., 2.21 per cent. Si; 1170 lb., 1.51 per cent. Si, and 2950 lb. scrap containing, approximately, 0.60 per cent. Si. The scrap and pig charged at 11:30 o'clock melted in 1 hour and 23 minutes, and was tapped 3 hours and 52 minutes later. The first test was dark speckled; 23 more tests were taken, none showing any improvement over the second test, which was somewhat lighter than the first. This heat was tapped when the test gave a clear fracture. Metal ran well.

*Findlay, Ohio.

The Heroult Electric Furnace, in the United States *

The United States Steel Corporation has decided to introduce the Heroult electric furnace and steel process, its engineers having made a close study of the general subject, extending over two years, and having made a number of visits to the localities abroad where electric furnaces and methods are in operation. At the same time its patent attorneys and experts made a thorough examination of the patents and of the state of the art.

The outcome of these investigations is that it has been decided to put up one 15-ton Heroult furnace at the South Chicago works of the Illinois Steel Company and one 15-ton furnace at the Washburn & Moen plant of the American Steel and Wire Company at Worcester, Mass. Probably a furnace at Homestead will follow. At the South Chicago plant, where three-phase current is available, both locally and from Gary, the purpose is to take the blown metal from the bessemer converter and refine it in the Heroult furnace for the manufacture of a specially high grade of steel rail, the capacity of the electric furnace being about 500 tons per day of 24 hours. As to the ability of the Heroult process to eliminate phosphorus and sulphur and to deoxidize the bath, overwhelming evidence has been accumulated abroad.

At Worcester the Heroult furnace will be served by two 50-ton open-hearth furnaces, and will be devoted particularly to the refining of the metal for use for the high-grade steels which the plant requires for the many lines of special wire products.

The United States Steel Corporation will, therefore, be the pioneer in introducing electric refining both in the manufacture of tonnage products like rails and special steels for the wire industry. The quality of rails has been a burning subject in recent years, and the plan of producing what will be equivalent to tool steel quality is one which raises high hopes for the future. In fact, the question suggests itself whether the verdict in favor of open-hearth steel which has been so freely given of late may not be reversed and whether the bessemer converter backed by the Heroult electric refining furnace may not yet come to its own within the enlarged field which the ability to utilize impurer ores will offer. It is even within the range of probability that for this service the 15-ton electric furnace does not represent the maximum unit, and that furnaces of larger capacity may be found practicable.

Hardly less interest attaches to the refining of open-hearth steel as at Worcester. Starting with a purer product from the steel furnace—whether it be acid with

selected raw materials or basic open hearth steel from materials of moderate purity—the electric refining process will yield a final metal very low in impurities, and thoroughly deoxidized, which will greatly raise the standard of quality.

Plans for the two plants are now being drawn, and construction will be pushed vigorously so that both installations will be in operation before the early summer.

D. W. Brunton

Mr. Brunton, who has just been elected president of the American Institute of Mining Engineers, was born at Ayr, Canada, in 1840. He studied engineering at

D. W. BRUNTON

Toronto, practiced three years in the East, then took a post-graduate course at the University of Michigan, and went to Colorado as mining engineer for the Dakota & San Juan Mining Company in the spring of 1875. He next took a position as engineer for the Hunt, Douglas & Stewart mill at Georgetown, Colo., where he remained until the summer of 1876, when he became engineer for the Clear Creek Reduction Works. In 1876 he went to Silver Peak, first as mining engineer and later as manager, for the Silver Peak Mining Company, and in 1880 went to Leadville, and in partnership with F. M. Taylor, built the Taylor & Brunton mill in California Gulch. The business management of the plant was placed in the hands of

Mr. Taylor, leaving Mr. Brunton free to devote himself entirely to professional work, in the course of which he became consulting engineer for the Dunkin, Robert E. Lee, Wolfstone and Dinero mining companies, and for a time was manager of the Colonel Sellers mine. In 1889 he became consulting engineer for the side-line mining interests in Aspen, and had engineering charge of the long and bitter litigation in that district. On the termination of the lawsuits Mr. Brunton became manager of the mines at Aspen where he remained until the spring of 1893, when he removed to Denver and opened an office as consulting engineer.

One of the most important undertakings carried on by Mr. Brunton during his management at Aspen was the Cowenhoven tunnel, a 2½-mile double-track bore, driven under Smuggler mountain for the purpose of affording drainage, transportation and ventilation to the principal mines of the district. This work, which was attended by many difficulties, attracted the attention of tunnel engineers in all parts of the United States. A paper on the methods employed in driving this tunnel, read before the Institution of Civil Engineers, brought him a Telford medal, and the miners, to show their appreciation of the care and forethought which made it possible to carry on the work from start to finish without a single accident, presented him with an elaborately engraved gold medal.

Mr. Brunton was one of the first to perceive the defects of the old-fashioned system of determining the value of ore by hand sampling, and after an investigation of the subject, invented what is known as the Brunton mechanical sampler, which was first installed in the Mathews & Webb plant at Denver. To realize greater returns from the invention than was possible by selling it under royalty, Taylor & Brunton built a public sampling works, utilizing this system throughout, in Aspen in the summer of 1889, and later extended this business until they now have a chain of samplers in Colorado, Utah and Nevada, which is perhaps the largest business of this kind in the world.

In the course of his professional career Mr. Brunton's mining trips have taken him into most of the principal mining districts of the world. He has made examinations from Alaska to Argentina, in addition to which he has traveled through Europe, Asia, Africa, Australia and New Zealand. Among his clients have been the Mines Limited of London, the Anaconda Copper Mining Company, Amalgamated Copper Company, New Jersey Zinc Company, Rio Tinto Mining Company, of Spain, and the Drainage Association of Cripple Creek.

The Robinson mine in the Transvaal reports for 1908 a total profit of 5,500,000 from its mill of 220 stamps.

Power from Copper Blast-Furnace Gases

Furnaces at Mansfeld, Germany, Carry Nearly 20 Per Cent. Coke and Yield Gas for Power Equivalent to 7.4 H.P. per Ton of Ore Treated

BY ROBERT SCHORR*

The famous Mansfeld district near Eisleben, Germany, and the metallurgical processes employed there are too well known to require description here. Some time ago the 700th year jubilee of the copper smelting works was celebrated, the occasion being honored by the presence of the German Emperor. The present company, which amalgamated the many independent interests, was organized in 1852. Since that time great progress has been made. The yearly report for 1907 states that 524,524 tons of *Kupferschiefer* (bituminous copper schist) and 151,890 tons of *Dachberge* (nonbituminous limestone, containing small amounts of copper) were mined, or a total of 676,414 metric tons. The copper schist contains from 1.8 to 3.7 per cent. copper in the form of bornite, chalcopyrite and chalcocite, and there are also small quantities of silver. The balance consists of about 40 per cent. silica,

to 0.5 per cent. of the total ore charge treated. From this source more than 200 tons copper, 383 tons lead, carrying 0.2 to 0.3 per cent. silver and 11.7 tons of nickelspeiss were obtained. It will be noted that the flue dust yielded more than 13 per cent. lead. The dust is mixed with ground shale and pressed into bricks which are calcined with schist before being smelted. There is a small blast furnace with four tuyeres at the Eckardt plant which is run periodically for this work.

The gas-engine plant of the Krughütte furnished in 1906 almost 7,000,000 kw. hours, and somewhat less in 1907. There are also a number of boilers fired with furnace gases, most important being the new installation of three 300-h.p. water-tube boilers at the Kupferkammerhütte.

OPERATIONS OF THE MANSFELD WORKS

Tables I and II summarize the smelting

products, reached a total of \$12,000,000, and the net profits were about \$1,400,000. About 23,000 men are steadily employed.

GAS-ENGINE POWER

In former years the waste furnace gases were used for raising steam and for heating the blast. The furnace gases at the first three works named in Table I have a heating value of from 590 to 630 cal. per cu.m., but in the fourth plant they are considerably poorer. The economy of central generating stations at this place is indicated by the fact that there are more than 350 steam engines representing 34,000 h.p. scattered over an area of about 60 square kilometers.

So far only the Krughütte has been equipped with gas engines. These are directly connected with electric generators, which furnish a three-phase current of 50 cycles and 3000 volts. Underground

Koch-Hütte	193,700	39,708	205	4	29.51	0.150	531	22.1	135
Eckardt-Hütte	128,700	22,812	189	2 to 3	29.95	0.163	331	13.8	151.1
Cu-Kammer Hütte.	130,400	19,299	148	2	28.35	0.161	356	14.8	168.5
Totals.	677,310	135,064	199.8		28.47	0.155	1854		

10.7 per cent. alumina, 5 per cent. ferric oxide, 19.5 per cent. calcium carbonate, 2 per cent. sodium carbonate and 10.3 per cent. water and bitumen. In the stated tonnage of *Dachberge* some nickel ores and sand are included. The average yield per ton of ore charge amounted, in 1907, to 2.847 per cent. copper and 0.0155 per cent. silver. More than 135,000 tons of coke, or almost 20 per cent. of the ore burden, were consumed in the matte-smelting operations.

In view of the low grade of the ore and the high cost per ton for mining and treatment (about \$9), great efforts have been made to utilize all waste products. The income from such sources amounted to almost 3,000,000 marks, two-thirds of this amount having been obtained from the sale of more than 18,000,000 slag bricks. The fumes from the matte-roasting kilns yielded about 24,000 tons of sulphuric acid, ranging from 55 to 66 deg. B., and 27 tons of ferrous sulphate. Only 2867 tons of flue dust were made, or recovered, equal

operations for matte (coarse metal) at the various Mansfeld works, and they give some segregated data pertaining to average daily charges and coke consumption. Round blast furnaces with deep crucibles are used throughout. They vary in size from 5 ft. 3 in. to 6 ft. 2 in. at the tuyeres, and are equipped with bell-and-hopper feed arrangements. The feed floor is from 24 to 30 ft. above the floor level, and the connections with the gas mains are placed directly below the feed floor. Spacious dust bins are provided. Each furnace has six tuyeres, and the blast pressure ranges from 2.9 to 4.4 in. of mercury, equivalent to a pressure of 22,765 to 34,540 oz. per square inch.

The ore charge consists of 1700 lb. of roasted schist, 600 lb. *Dachberge*, 100 lb. slag and 100 lb. skimmings. Table II shows the amounts of matte produced and the grade. The work of the reverberatory furnaces is outlined in Table III. The production amounted to 19,240 tons of copper, and more than 96 tons of silver. The receipts from sales, inclusive of by-

TABLE II. MATTE PRODUCTION, MANSFELD WORKS, 1907.

	Tons.	Copper per Ton Kilograms.
Krug-Hütte	16,785	72
Koch-Hütte	11,059	59
Eckardt-Hütte	8,769	73
Kupfer-Kammer-Hütte.	9,400	72
Total.	46,012	

cables are employed for distribution. Table I shows that the Krug furnaces smelted at an average 636 tons of ore daily, or 26½ tons per hour. For every ton of ore approximately 800 cu.m., or 28,250 cu.ft. of gas is evolved, or 21,200 cu.m., 748,680 cu.ft. per hour for the whole charge. These quantities vary to some extent, depending entirely upon how the furnaces are operated.

The gas supply is fairly steady, as it is aimed never to have more than one furnace cut off from the mains; it is necessary to cut off the furnace while feeding. The average heat value of these gases is 600 cal. per cu.m., or about 68 B.t.u. per cu.ft. This is about two-thirds of the calorific value of an average gas from iron-blast furnaces, which always contains 13½ to 2 per cent. of hydrogen; copper-furnace gas carries no hydrogen and consists of 9.2 to 10.8 per cent. carbon dioxide, 19 to 24 per cent. carbon monoxide, the remainder being nitrogen. The fluctuation in heat value amounts to about 10 per cent.

EFFICIENCY

In view of the large power expenditure

*Consulting engineer, San Francisco, Cal.

required for cleaning the gas and for the compressing of such lean charges in the engine itself, it will not be safe to figure on less than 2700 cal. or 10,711 B.t.u. per effective horsepower-hour, corresponding to a gas supply of $4\frac{1}{2}$ cu.m. or 159 cu.ft. The heat equivalent of one horsepower being 736 cal. or 2545 B.t.u., we have $2545 \div E. 10,711$ or the thermal efficiency of the gas engine $E. = 23.76$ per cent. Better performances are on record, established by careful tests made under ordinary conditions and without previous cleaning of valve chests and cylinders. Since 21,200 cu.m. of gas is available per hour, this represents a total of $21,200 \div 4.5 = 4700$ h.p. equivalent or continuously 7.4 h.p. equivalent for every ton of ore treated in 24 hours. The power equivalent for every ton of copper made in 24 hours is then $7.4 \times 37 = 273.8$ h.p., since 37 tons of ore are smelted for every ton of copper produced. In all more than 41,000,000 horsepower-hours, or more than 30,000,000 kilowatt-hours could be generated at the Krughütte alone.

The gas as it leaves the four furnaces is entirely unsuitable for direct use in gas engines, because it contains 17 grams of

passed into a gasholder of 500 cu.m. capacity. More recently a second holder of 4000 cu.m. has been added, and also gas filters placed at the engine house. These filters are similar in construction to an ordinary scrubber, but they are arranged horizontally, and instead of wooden trays, beds of iron turnings are placed vertically at intervals. The gas leaves the filters with a temperature of 21 deg. C., and it is under a pressure varying from 1 to 5 cm. of water column.

THE GAS ENGINES

The first installation of two 125-h.p. four-cycle Körting gas engines has been working almost steadily since 1901. The two 1300-h.p. Oechelhauser-Borsig engines operate on a two-cycle, and are single acting. They have been continuously in commission, day and night, for more than $3\frac{1}{2}$ years. The latest addition is an 1800-h.p. two-cycle Körting engine built by the Klein Engineering Works of Domburh. This unit was completed last April, was placed in service June 9, 1909, and has since run satisfactorily. This completes the original plan for the Krughütte gas-engine central station, bringing

per kg., or 6300 B.t.u. per lb., are employed with coke breeze in the proportion of three to one, the cost of enrichment being only 2 pfennigs per kilowatt-hour. These generators are arranged for hand feeding. The generator gases pass through coolers and scrubbers, as in the usual standard gas plant, to remove tar, ammonia, etc. In view of the small quantity of gas which will be required for the enrichment of the blast-furnace gases, there may have been no necessity to go to this complication and expense. It is also contemplated to use at times coke breeze and brown-coal coke screenings (*Grude*) instead of locomotive cinders.

The gas-engine plant of the Krughütte has been utilized to less than its full capacity, in order to avoid temporary overloads caused by the many and widely distributed secondary movers. In spite of this the financial result has been rather satisfactory. The total expenditure for operating and fixed charges in 1907 amounted to 122,512 marks, equal to about 0.67c. per kilowatt-hour. The results in 1906 were a little better, figuring 0.51c. per kilowatt-hour, or about \$33 per horsepower-year. With the full plant in operation the average yearly load factor will be considerably higher, and a further marked reduction in the power cost will be effected.

I am indebted to Otto Scharenberg, the engineer-in-charge, for much of the information used in the preparation of this article.

Australian Gold Production

The Queensland Mines Department reports the gold production of the State in January at 24,500 oz., or \$506,415. Of this, 400 oz. was placer gold, the rest from quartz mines. Mount Morgan reported 5409 oz. of the total.

Victoria gold production in January was 40,848 oz., or \$844,328 in value.

The production of Western Australia in January was 132,267 oz. fine gold, or \$2,713,059. This output was 17,552 oz. less than in December, and 6893 oz. less than in January of last year.

The gold production of New South Wales in January was 19,885 oz. or \$411,023. The mineral production of the State for the year 1908 is valued at £8,609,607. This includes £954,854 for gold; £2,947,824 for lead and silver; £502,812 for copper; £205,447 for tin; £3,353,093 for coal. The coal production was 9,147,025 tons.

Correction

In the article on the "Progress of Gold Mining in North Carolina," by E. W. Lyon, in the JOURNAL of Feb. 6, 1909, the beginning of the third paragraph of the third column on page 206 should read: "The discharge ends of machines are set 8 in. and 4 in. higher, respectively, than the feed end."

TABLE III. REVERBERATORY SMELTING, MANSFELD WORKS, 1907.

Plant.	MATTE, TONS.		Flux (Sand-arcs), Tons.	COAL, TONS.		Matte Per Day Per Furnace, Tons.	Copper in Product, Per Cent.	Silver in Product, Per Cent.	Number of Furnaces.	Black Copper Product, Tons.

dust per cu.m. and also sulphur, arsenic, potassium, cyanide, etc. It is therefore, first cleaned, the two gas mains feeding from the furnaces to Theisen gas washers. There are three washers housed in one building; two have a capacity of 6500 cu.m. of gas per hour each, and one is built for 15,000 cu.m. This makes a total capacity for the whole installation, of 28,000 cu.m. of gas per hour. The temperature of the entering gases is about 300 deg. C. or 752 deg. F. About 25 gal. of water are required for every 1000 cu.ft. of gas, or about three liters per cu.m. The power consumption for every 1000 cu.m. is at an average 6 h.p. or above 234 per cent. of the power represented by the purified gases.

The gas contains, after cleaning, only 0.003 to 0.005 gram solid matter per cu.m. The water from the washers is run into large settling tanks, the deposits in which carry up to 25 per cent. lead. The deposits are filter-pressed and treated for lead and silver with the balance of the flue dust, as obtained from the dust chambers in the furnace building.

In the original installation, the gases, after leaving the washing plant, were

it up to a rated capacity of 4650 h.p. The new large engine has a stroke of 1300 mm. and is designed for 86 r.p.m.; the 1300-h.p. engines have a stroke of 950 mm. and make 125 r.p.m. All engines are directly connected to three-phase generators of 50 cycles and 3000 volts. The two smaller engines are in a separate building.

Much trouble has been caused by fluctuations in the percentage of carbon monoxide and carbon dioxide. As long as the ratio $CO_2:CO$ is in the neighborhood of 1:2 the engines work perfectly, the compression averaging 16 atmospheres, or 227.6 lb. per sq.in. This is very high, and only possible with poor gas, without causing premature explosions. The work of compression is correspondingly high, amounting to about 9 per cent. of the cylinder duty. The pressure of explosion is 25 atmospheres, or 355 lb. per square inch.

To assure a uniform quality of gas, or to permit enrichment in the case of a sudden rise in carbon dioxide, the company has installed quite recently two Pintch gas generators with a combined capacity of 3000 cu.m. per hour. Locomotive cinders, which average about 3500 cal.

Economics of Steel Prices

The announcement on Feb. 19 that "official price schedules" for steel products, rails excepted, had been abandoned—in other words, that competition now is to be free and that all producers will sell at such prices as they may see fit—was in some ways the most important and most truly historic event since the panic of 1907, remarked *The Evening Post*. That it marked the withdrawal from the publically promulgated theory of 1908, that economic depression and paralysis of consuming power were no conclusive reasons for reducing prices, was itself a matter of great significance; because, if that theory had been vindicated, a good part of the time-honored principles of political economy would have had to be discarded. But the scope of the steel trade's action is wider than the steel trade; it has to do with the whole problem of consumption and prices in hard times.

Even the three-dollar concession of last June was granted unwillingly and under protest; it was alleged, by way of argument against it, that it would not elicit an additional dollar's worth of orders. But this, quite obviously, was an argument wholly from the producer's point of view. If every industry dominated by a great corporation had adopted the same principle and had been able to hold prices permanently, any consumer of merchandise can see what his position would have been.

There are two distinct views expressed, in both financial and industrial circles, over the recourse to an "open market" in the steel trade. One, and the most obvious, was that a dangerously unsettling condition of things had come about, that profits in a basic industry were presently to be slaughtered, and that no one could read the future. The other held that a wholly artificial and untenable situation had been abandoned with a view to readjusting conditions to a basis where makers and consumers might meet on equal terms, break the long deadlock by gradual resumption of activity, and build from the bottom up for the new and certain era of prosperity. Even if the breaking-down of the "stand-pat policy" on prices means a leap into the unknown, the continued maintenance of that policy would equally have meant a pause on the brink of the gulf, into which the trade was well aware it must sooner or later plunge.

The "open market" of 1900 was in reality a result of the Boer war panic; for our steel trade, during 1899, had been relying largely on the huge mass of export orders placed by the booming industry of Europe. The financial collapse in England and Germany, and the fall in foreign steel prices, forced a reduction in our own steel market; it was not until October, 1900, when steel prices had been cut from the exorbitant \$41 per ton of October, 1901, to \$17, that the market righted

itself. The price was back at \$22, on a greatly improved trade, before the ensuing spring; after that, the United States Steel Corporation took the field.

In other words, little more than half a year elapsed, after the panic of 1893, before the open market had brought producers and consumers together on a stable basis; in 1900, a full year had elapsed. In neither year was there present the conserving and restraining power of a dominant corporation in the trade; in both, the lower level fixed turned out to be a spur to American ingenuity and enterprise, which presently sent our steel manufacturers into a broader field, where we met and conquered the rest of the producing world.

Duty on Zinc Ores

SPECIAL CORRESPONDENCE

The Treasury Department has acquiesced in the decision of the court in the zinc ore case. It is now expected that the next move in the controversy will be the raising of a case in court to determine the meaning of the words "lead-bearing ores" in paragraph 181 of the Dingley act reading "lead-bearing ores of all kinds 1½¢. per pound on the lead contained therein." This grows naturally out of the points settled in the case now accepted by the Government as closed. The Treasury Department makes its official announcement in a letter to the Collector of Customs at Corpus Christi, Texas, in which it says in part: "The Department is in receipt of a letter from the Attorney-General in which he states that no steps will be taken looking to a review of the decision of the United States Circuit Court of Appeals for the Fifth Circuit in suit No. 1961, United States vs. C. G. Brewster, involving the classification of zinc ore known as carbonate, silicate, and sulphide of zinc. The carbonates and sulphides were assessed with duty under paragraph 183 of the tariff act as crude, metallic, mineral substances, and the court affirmed the decision of the Board and Circuit Court that the carbonates are free of duty under paragraph 514 as calamine, and the sulphides are free of duty as minerals crude under paragraph 614. You are, therefore, hereby authorized to forward a certified statement for the refund of the duties collected in excess in this case. While the Circuit Court of Appeals affirms the decision of the Board and Circuit Court that the ores are free of duty, it sustained your assessment of duty under paragraph 181 upon the lead contents without regard to the percentage of lead contained therein and you are hereby instructed to assess duty upon the actual lead contents in future importations of such ores."

Economic Law Prevails

The meaning of the situation which was publicly recognized in the steel trade, today, is not at all mysterious, said *The Evening Post*, Feb. 19. Economic law has asserted itself, and the attempt, honestly but mistakenly entered upon last year, to prevent its operation through the power of aggregated capital, has broken down. That it was bound to do so eventually, on any other supposition except that the financial panic of 1907 was a mere teapot tempest, has been the belief of perhaps the majority of experienced business men. The mistake in last year's "stand-pat policy" on prices lay in its fundamental assumption that, since buying orders would not be instantaneously stimulated by a cut in prices during severe industrial depression, therefore no decline whatever in prices ought to be permitted. From such a position it was but one short step to the corollary which the Steel Corporation's chairman openly accepted, last April, that increased demand was not a deciding factor in higher, or increased supply in lower prices. The quite conclusive answer to that theory was, that it discarded entirely the function of great corporations as the regulators of prices—a perfectly normal office—and made them the absolute dictators. To hold the price of an industrial staple at the high level of prosperity, in the face of industrial depression and impaired consuming power, was every whit as unreasonable, from an economic point of view, as to have made a radical cut in prices at the height of legitimate trade demand in 1906. The Steel Corporation wisely regulated trade that year by preventing a "runaway" advance in prices; it might have used, and still may use, its powers wisely in the existing situation to prevent an absolute slaughtering of values such as should throw industrial projects into chaos.

Recent investigation by the Government, through the Forest Service, as to the effect of bleeding pine trees of their resin has shown the following results: (1) that bled timber is as strong as unbled if of the same weight; (2) that the weight and shrinkage of the heartwood is not affected by bleeding; (3) that the durability of the heartwood is not affected by bleeding, since the resin comes from sapwood only. The investigation involved mechanical tests and the physical and chemical analyses of the wood of bled and unbled trees from the same locality.

The world's output of graphite is estimated by the Geological Survey of India to be in the neighborhood of 70,000 to 80,000 tons per annum. Of this about one-third comes from Ceylon. The Travancor state, of India, in 1906 produced about 2600 tons.

Rescue Apparatus

Mining men have recently busied themselves in studying the different types of rescue apparatus now on the market. Each manufacturer claims that his machine has all the virtues, while among the miners themselves, each rescue brigade at its respective station appears to have some favored form. Among the many machines now being used are the Draeger, Fleuss, Shamrock, Weg, and a liquid-air apparatus. A number of engineers are coming to favor the use of liquid air as an agency in rescue work, basing their preference for this machine on the fact that it provides a low, refreshing temperature to the air supplied to the wearer. Another point in favor of this apparatus is that it has only one valve (the outlet valve) which is an item of much importance, as valves are generally looked upon with suspicion. The chief argument advanced against this type of apparatus is the rapid evaporation that takes place, amounting in some instances to as much as 5 per cent. per day. One large coal company, however, has ordered a complete equipment of this type, and is now putting in a liquid-air plant of its own.

Many engineers object to the Draeger apparatus, because it uses a helmet, and the fact that the pressure gage is not accessible for inspection by the wearer of the apparatus. This gage is fixed behind, and another person must consult it for the wearer. Those who advocate the Draeger apparatus claim that the giddiness and faintness sometimes experienced, are not due to the head being boxed up in a helmet. They declare these symptoms are caused by poisoning from CO_2 , there being at the time a preponderance of this gas in the breathing bag.

With regard to the gage being situated at the back of the wearer, this, of course, could be remedied at the cost of introducing a rubber-tube connection, which, however, would provide another source of weakness. Some of those who oppose the oxygen breathing apparatus claim that the men work at a greater rate than when a normal atmosphere is breathed. One authority in investigating this condition states that men breathing pure oxygen do not consume any more than they would if they were breathing atmospheric air. This same authority says that in breathing air containing from 9 to 63 per cent. of oxygen, there is no noticeable change in the sensations of the rescuer. It is only when the percentage of oxygen falls to 7 or 8 that a condition of numbness sets in. The human body is able to satisfy its needs of oxygen, provided that the inspired air contains from 10 per cent. the inspired air contains from 10 per cent. upward. It is difficult, therefore, to understand how increased energy can arise from breathing air containing an excess of oxygen.

Colliery Notes

In order to protect men at the shaft bottom, cage bonnets should be made high enough so that falling coal striking the bonnets will not be thrown into the entry.

On the continent, three-phase alternating current is often preferred to the continuous current in coal mines, on account of the danger supposed to lie in the commutator. Continuous-current motors generally spark at the brushes.

In inclined workings, tapered or sharpened props last much longer than those of uniform thickness. The former are also more economical, more efficient, and safer. Tapered props can also be taken out of the mine, re-tapered, and used in a thinner seam. Lastly, the tapered prop is more easily withdrawn.

The most favorable months of the year for cutting timber are December, January and February. During these months there is comparatively little sap in the trees. Timber cut when the sap is circulating through the tree decays rapidly. Seasoned timber will last fully one-quarter longer than green timber.

The efficiency of safety catches should be carefully tested at regular intervals. In making this test, the cage is generally raised above the top platform, and heavy timbers are laid across the head of the shaft to catch the cage, should the catches fail to work. The rope is then cut and the cage stopped by the catches.

The cost of electric power depends largely on the size of the plant. Centralization is the idea now being supported by good authorities. Statistics from England show that at a plant having an output of 2500 kw., the cost per kilowatt was \$268. The total cost of this plant was \$700,000. At another station having an output of 40,000 kw. and costing \$5,800,000, the total cost per kilowatt was only \$139.

When mules are used to gather cars at the face, the maximum distance the animal should haul is generally determined by the ability of the mule to haul the required quantity of coal to the parting as fast as it is hauled to the shaft bottom. This distance may vary from 600 to 2000 ft. In mule haulage, two drivers are preferable, since they can assist each other when cars are derailed. Except where the grades are steep, the drivers should follow each other rather than make alternate trips.

Where there are several landings in a shaft, great care should be taken in the arrangement of signals. A good plan is to safeguard against danger by providing for each landing a distinct bell that cannot be mistaken as belonging to any other level than the one with which it is connected. Strict rules should be enforced, prohibiting the movement of a cage from any

landing before the engineer has received and responded to the signal given at that landing. When work is temporarily abandoned at any level, the safety gates should be locked or otherwise made secure.

In firing shots of high explosives, safety is obtained in proportion as the stemming is complete. One authority says that in ordinary shot-holes, he considers a safe proportion is a minimum of 9 in. of stemming to a charge of 3 oz. of high explosive, with a proportionate increase of stemming for larger charges. The knowledge that shots charged with a high explosive will blast the work required with little or no stemming, has caused a mistaken idea that the stemming of shot-holes is of only minor importance. Every experienced miner knows that shots fired without proper stemming emit a dangerous amount of flame, sufficient in most cases to ignite either firedamp or coal dust.

Every coal mine should have as a part of its equipment, a reliable barometer, so that careful readings of atmospheric conditions may be registered daily. An electric barometer has recently been invented, which depends for its operation upon the short-circuiting of a U-shaped carbon filament by means of a barometric mercury column. The filament dips into the top of the column, and as the atmospheric pressure increases the mercury rises in the tube, cutting down the length of the exposed part of the filament, and thus reducing the resistance. As the mercury is also affected by temperature, a second filament and mercury column is provided. In this latter column, the tube is sealed, so that the mercury will not be affected by atmospheric conditions.

Sixteen highly insulated, lead-covered, and armored cables, each carrying 100 e.h.p., will be much more expensive than four cables each carrying 400 e.h.p. Where all the current is required for a long-distance transmission, it is probable that for a great part of the distance all the current can go in large cables and at a reduction of perhaps 20 per cent. in the average cost per horsepower transmitted. If, for instance, we transmit our current two miles, with 400 volts at the motor, and a drop of 10 per cent. per mile from generator to motor, the cost of the cable for 100 e.h.p. will be approximately \$12,000, and erection \$2000. If these figures were multiplied by 16, we would have nearly \$230,000 as the cost of the cables and of erection; however, if all the power were taken this distance in four large cables, each of 400 h.p., the cost of the cables would be reduced 20 per cent. In deciding a problem of this character, we have to reconcile two conflicting needs: First, the convenience and safety of low-tension motors; second, the economy of high-tension mains.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Pres. and Treas. ROBERT MCKEAN, Sec'y.

505 Pearl St., New York.

London Office: 6 Bouverie Street, London, E. C., Eng.

CABLE ADDRESS "ENGINEING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines. \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newspapers generally.

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for January, 1909, was 54,000 copies.

February 6, ...	12,000
February 13, ...	10,000
February 20, ...	10,000
February 27, ...	10,000

None sent free regularly, no back numbers. Figures are live, net circulation.

The Cut in Steel Prices

In the JOURNAL of Feb. 6, we said: "In this country the Steel Corporation has been the leading exponent of the theory that reductions of prices were unwise and unnecessary. We have repeatedly argued against that fallacy, as have other journals. We understand that the directors of the Steel Corporation at last recognize among themselves that they were mistaken."

With that change of mind, it was, of course, only a question of time when a reversal of policy would be made. This was announced on Feb. 19, when radical cuts in the prices for steel products were made. This led to more or less demoralization in the stock market, where it is reckoned that the profits of the Steel Corporation will be seriously diminished. That does not necessarily follow. In the first place, there is likely to be a readjustment of wages, which matter is indeed taken care of in the cases of those companies which pay their men upon a sliding scale; in the second place, the cut will sooner or later stimulate business and enable the works to operate more nearly at full capacity, which will be more economical than the half scale or five-eighths scale of the last year and more; in the third place, it is apt to be more profitable to sell a lot of goods at a small profit than a small amount at a large profit, the latter being what the Steel Corporation has lately been doing.

If there be anything in economic theory—all recent experience, as well as all prior, proves that there is—the fallacious ideas of the managers of great aggregations of capital have been one of the most influential factors in retarding the return of prosperity, and consequently their retreat, is one of the best things that could happen.

Mr. Carnegie remarked recently that it is a great mistake to try to hold up prices in time of panic. If he had been at the head of the Steel Corporation, he said, his policy would have been to reduce prices enormously, so that a man contemplating the erection of a skyscraper would say: "Here's a bargain. I will buy my steel and start work at once." This would be followed in other parts of the country and business would begin to pick up. We do not doubt that this will now come about—not right away, but much more quickly than otherwise was to be expected.

Chinese and Negro Labor in the Transvaal

The question of mine labor in the Transvaal having been finally decided by the legislature of that colony, which enacted a law requiring the deportation of the Chinese laborers as fast as their contract terms expired, the work of returning them to their own country has gone on steadily for over two years, without seriously interfering with the operation of the mines, notwithstanding the predictions made when the law was under discussion.

The total number of laborers reported in Transvaal mines—excluding white men—has been as follows for two years past, at half-yearly intervals:

	Kafirs.	Chinamen.	Total.
Jan. 1, 1907.....	83,507	53,828	137,335
July 1, 1907.....	89,593	51,441	141,034
Jan. 1, 1908.....	118,204	31,840	150,044
July 1, 1908.....	132,339	18,413	150,752
Jan. 1, 1909.....	148,722	12,283	161,005

In the two years there was an increase of 65,155 Kafirs, and a decrease of 41,545 Chinamen; a net gain of 23,610 laborers. This does not imply that the efficiency of the Kafir is less than that of the Chinaman. More laborers have been needed, owing to the extended operation of many mines, the increase in tonnage taken out owing to the working of lower-grade ore, and to the inclusion of some new mines. The handling of the lower-grade ore alone required a considerable increase in the working force in the mines and at the mills.

The larger force of natives has been obtained with little difficulty, owing to the concurrence of several causes. These were the discontinuance of railroad and other public works; the impoverishment of the natives over a considerable part of South Africa by the loss of cattle from plague; and the extension of recruiting operations for the mines over Portuguese and other territory heretofore untouched. A considerable number of negro laborers are now being brought to the Transvaal from the Zambesi country. These men are hardly the equal of the Kafirs in physical strength and in intelligence, and they require acclimation after their transition from their own hot, moist climate to the cooler region of the high veldt; but they are generally tractable and make good laborers when they become accustomed to the climate and the work.

The enactment of the deportation law

was the result of political rather than economical considerations, since the Chinese, as a rule, were fairly good mine laborers. The question has been heretofore fully discussed, so that it is sufficient to say here that the government seems to have been wise in its determination to eliminate the Asiatic element from the already mixed population of the Transvaal. It may be added that the importation of some 60,000 foreign laborers into the country within a few months, and their return to their native country in three years—for the last of them will probably go during the present year—with so little disturbance, constitutes one of the remarkable industrial movements of modern times.

The Revelation of a Metallurgical Secret

For many years, until a portion of it was destroyed by fire, the Argo works (near Denver, Colo.) under Dr. Richard Pearce, was one of the most instructive metallurgical plants of the world. Its rather exceptional processes were always an object of interest to visitors in Denver, to whom the works were thrown open, and they were described in important papers in the *Transactions* of the Institute. However, there was one department of the works to which visitors were never admitted, and of which no description was ever published. This was the department in which the gold-copper bottoms were refined. Doctor Pearce remarked in his presidential address before the Institute in 1883, "The treatment of this alloy and the separation of the gold from the copper is a part of the process which, for certain business considerations, I am not at liberty to describe." Many efforts were made by rival and curious metallurgists to discover this secret, but always without success.

The gold and silver refinery of the plant was destroyed by fire in 1906. In view of the development of modern practice in the refining of copper matte, etc., the management decided that it would be inadvisable to rebuild that part of the works. In a paper by Harold V. Pearce, in the *Bulletin* of the Institute for February, 1900, he says: "This decision probably removes altogether from the sphere of practice the Pearce method for the separation of gold. At all events, it removes the business reasons which have prevented

hitherto the publication of the principles involved. At the suggestion of Doctor Raymond, secretary of the Institute, my father, Richard Pearce, the former manager of these works, has requested me to prepare a brief description of this process for the benefit of our members."

In the first place, it is interesting to chronicle how the process was evolved. In the early days of smelting at Black Hawk, the gold-copper bottoms were shipped to Boston for refining. This led to many annoying features of business. Doctor Pearce inaugurated a series of experiments, unknown to Professor Hill, to prove whether an idea that had occurred to him had any merit. Having satisfied himself by producing a lump of gold weighing 2 or 3 lb., and having explained to Professor Hill how it was done, the latter immediately ordered the Boston works to be closed after finishing the stock of material on hand, inasmuch as future refining was to be done at Black Hawk. The new process solved the whole problem, each metal being put into marketable form; the gold in bars ranging upward from 900 fine; silver in bars 999 fine, and copper as bluestone. During the 30 years that this process was used, 1,532,905 oz. of gold were extracted by it from 54,549 tons of copper.

Now for the secret disclosed by Mr. Pearce. If the gold-copper alloy in the form of copper bottoms be granulated and melted with a suitable quantity of pyrite, there results a matte and a copper-bottom, the latter carrying the bulk of the gold present in the original alloy. The iron sulphide acts upon the copper, producing a compound of copper with iron and sulphur, corresponding closely to the mineral bornite both in appearance and composition. The second bottom, being melted, refined, and again granulated, is once more melted with pyrite, a further quantity of copper combining with it to form matte, and a smaller amount remaining as metallic copper, still carrying the major portion of the gold. The process is, therefore, a series of refining with granulations and subsequent treatments, or "strippings," with pyrite, with the result that the whole of the copper is finally extracted or "stripped" from the gold. A certain quantity of gold passes into the matte at each stripping, but any attempt to remove too large a proportion of the copper in one operation results in too much gold being taken up by the matte. The process is

described in detail in the paper by Mr. Pearce, from which we have been quoting.

In conclusion, Mr. Pearce remarked that "the process was never materially changed from the time it was first placed in operation in Black Hawk until the works were destroyed by fire. It is quite possible that the simplicity of the method of separation accounts for the fact that it was not developed before." Perhaps also it is the reason why the nature of the process was not surmised by outsiders; it is always the simple and obvious to which eyes are shut. However, it is certainly remarkable that this secret was preserved so completely for the long period of its use.

Carroll D. Wright

The death of Carroll D. Wright removes a public servant who for many years was content to do his work faithfully and with understanding without seeking for special reward; and this course brought him into the prominence which he had not sought. Few men understood the true value and uses of statistics better than he; and few had studied labor questions in their various phases more thoroughly and carefully. Perhaps the service which brought him most into general public notice was on the Anthracite Strike Commission of 1902-3. The shaping of the work of that commission was largely due to Colonel Wright's advice; and to him and to Judge Gray was due the organization of the conciliation board, which proved such a valuable part of the commission's settlement.

Colonel Wright was an indefatigable worker, and not even the incurable disease which shadowed the closing year of his life could keep him from doing what he could to forward his chosen work.

THE SECRETARY of a Comstock Mining Company, who is now a fugitive, appears to have developed the art of milking suckers to the highest point yet reached in the history of 50 years of nefarious transactions in connection with the Comstock lode. This brilliant gentleman issued 22,500 shares of fictitious stock of the Belcher Silver Mining Company, sold it, put the money in his own pocket, levied assessments on the fictitious stock along with the real stock, and appropriated those proceeds.

Spelter Statistics for 1908

BY W. R. INGALLS

For the sake of promptness I am publishing the statistics of production without waiting for those pertaining to consumption, the collection of which is more laborious.

The production of spelter in 1908 is given in Table I, which is based on reports from all of the smelters.

I. PRODUCTION OF SPELTER.

(IN TONS OF 2,000 LB.)

State.	1907. Tons.	1908. Tons.
Colorado.....	5,200	3,079
Illinois.....	56,103	59,244
Kansas.....	133,561	99,136
Missouri.....	11,594	10,196
Oklahoma.....	5,094	14,867
South and East.....	38,060	32,989
Total.....	249,612	210,511

There was no addition to smelting capacity in 1908, excluding the new plant at Danville, Ill., and the two new works at Bartlesville, Okla., which went into operation just before the end of 1907 and were completed early in 1908. Otherwise no smelter added so much as a furnace. So far as I am aware no plans for new plants were prepared during the year.

All of the smelters but three reported the stock of spelter at their works on Dec. 31, including that held for speculation. The total of their reports is 19,848 tons. This is a little less than was previously reported to me as of Dec. 15. Allowing for the companies that did not report I estimate the stock in first hands on Dec. 31 to have been 25,000 tons. The delivery into consumption is computed in Table II.

II. DELIVERIES FOR CONSUMPTION.

(IN TONS OF 2,000 LB.)

	1907. Tons.	1908. Tons.
Stock January 1.....	4,550	32,883
Production.....	249,612	210,511
Imports.....	1,778	881
Total supply.....	255,940	244,275
Exports.....	563	2,640
Stock, December 31.....	32,883	25,000
Deliveries.....	222,494	216,635

In considering the figures in Table II it is important to make a distinction between "deliveries" and "consumption." The zinc industry joins hands with iron and copper, which are represented by the galvanizers on one hand and the brass-makers on the other. The consumption of iron and copper in 1908 was not more than 70 per cent. of that in 1907. It is unreasonable to suppose that the consumption of spelter did not fall off more than 5 per cent. Discussion of this subject must be deferred until the reports from the smelters of dross and other secondary material are in hand, together with the reports from the consumers.

PRODUCTION OF ZINC ORE

Every smelter in the United States re-

ported his receipts of ore, enumerated according to State and country of origin. The totals are given in Table III.

III. PRODUCTION OF ZINC ORE IN THE UNITED STATES.

(IN TONS OF 2,000 LB.)

State.	1907. Tons.	1908. Tons.
Arizona.....	285	879
Arkansas.....	4,088	2,582
Colorado.....	(a) 142,510	(b) 82,852
Idaho.....	11,847	1,558
Kentucky.....	1,005	341
Missouri-Kansas.....	297,126	273,420
Montana.....	1,218	2,783
Nevada.....	4,593	1,445
New Mexico.....	4,281	2,290
New Jersey.....	368,710	(c)
Oklahoma.....	3,250	9,300
Tennessee.....	1,071	566
Utah.....	9,043	709
Wisconsin.....	53,011	58,135
Others.....	885	85
Totals.....	902,923	6,157
British Columbia.....	1,157	6,157
Mexico.....	108,800	66,383
Grand totals.....	1,012,880	

(a) Includes receipts of ore for making zinc-lead pigment at Canon City, Colo. (b) Does not include receipts of ore for making zinc-lead pigment at Canon City, Colo. (c) Not given, because it would practically disclose the business of a single company.

Determination of Gold in Copper Bullion

BY FRED F. HUNT*

The amount of work necessary in the "all-fire" method for the determination of gold in copper bullion has led to investigation for shorter methods for this purpose. Experience has shown that with only concentrated sulphuric acid too much sulphide of copper was formed to allow of good cupellation with only one scorification. To overcome this, mercuric sulphate has been used, but owing to the formation of globules of mercury and their possible loss, with a resultant loss in gold, this method has not been generally employed.

In dissolving the borings with sulphuric acid there seems to be more sulphides formed at the beginning of the action than later. This suggested the use of cupric sulphate with sulphuric acid and I found that this combination left such a small amount of sulphides that the usual scorification with 35 grams of test lead gave a button that was readily cupelled.

The following details are observed: To 80 c.c. of concentrated sulphuric acid add 25 c.c. of a solution of cupric sulphate (160 grams per 1000 c.c.), using a low, wide No. 5 beaker. Heat this mixture to such a temperature that on the addition of the borings action commences immediately; add 1 a.t. borings, spreading them over the bottom of the beaker, heat until all dissolving action has ceased (from 1 to 1½ hours), cool, add about 400 c.c. water, stirring to prevent caking of the crystals, bring just to a boil, filter and wash the beaker thoroughly, using a rubber-tipped glass rod as "scrubber." Place filter paper with precipitate in a 2½-in. scorifier, dry and burn off the paper, add

about 35 grams test lead and 1 gram ground silica, scorify to button of about 9 grams, cupel and part as usual.

Silver may also be determined by this method by adding to the filtrate from the gold enough solution of permanganate of potash to produce a permanent color, then 1 drop of saturated salt solution and 10 c.c. of a 10-per cent. solution of acetate of lead; stir well and let stand over night, filter with the usual precautions, add paper and precipitate to the same scorifier with the gold and proceed as in the case of gold only.

"Blue Gas," a New Illuminant Used in Germany

BY ROBERT GRIMSHAW*

In Germany there is being introduced a new system of illumination based on the same principles as that for railway-car lighting. This illuminant is called "blue gas." The gas is delivered in liquid form, in such shape that it may be used in closed rooms in hanging burners giving from 50 to 1000 c.p. To use the gas all that is necessary is to pour the liquid from the steel cylinders, in which it is delivered, into the gasometer. This is almost as convenient as having one's own gas plant, for one can protect himself against accidents at the factory or delays in transit by always having on hand several filled cylinders. A cylinder contains 22 lb. of the gas, and costs 12 marks, or about \$2.86. This quantity will supply a 50-c.p. burner for 480 hours, so that this illuminant appears to be cheaper than petroleum. This "blue gas" can, of course, be used for heating and cooking as well as for forging, hardening and tempering, and other industrial processes. It is a hydrocarbon compound, free from carbon monoxide, and is not poisonous; its heating effect is 15,000 units against 4500 of ordinary coal gas. The gas is burned at a pressure of about an inch of mercury, or 13.6 in. of water at the burner. Almost any apparatus that is arranged to burn ordinary coal gas or acetylene gas can be altered without much difficulty to burn this; and in such cases all that is necessary is to make the connection between the cylinder and the house pipes through a reducing valve.

As regards its explosibility, Professor Götz of Augsburg reports that, while the range of explosibility of acetylene gas when mixed with air is between 2 and 49 per cent. (a range of 47 per cent.), and that of ordinary coal gas is between 6½ and 19½ per cent. (a range of 13 per cent.), that of "blue gas" is only between 4 and 8 per cent. (a range of 4 per cent.). No special permission from the authorities or the insurance companies is necessary for its use.

*Chemist, 77 Pine street, New York.

*Mechanical engineer, Dresden, Germany.

The International Conservation Conference

SPECIAL CORRESPONDENCE

The meeting of the International Conference called by President Roosevelt, began in Washington on Feb. 18, with a reception by the President for the Canadian and Mexican commissioners at 10 o'clock in the East room of the White House. Later the conferees proceeded to the Diplomatic room of the State department for regular sessions. The remainder of the morning was taken up with formal addresses of welcome and responses of the visitors. In the afternoon the conference began its work in earnest.

The delegations from Canada and Mexico include men known as experts in the natural resources of their countries. Canada is represented by Hon. Sydney Fisher, minister of agriculture of the Dominion; Hon. Clifford Sifton, ex-minister of the Interior, under whose administration many of the regulations concerning the use of Canada's resources were adopted, and Dr. Henri S. Beland, a member of the Canadian parliament, a well known authority on these subjects. The Canadian delegation is accompanied by Robert E. Young, land expert in the Canadian Department of the Interior, who acts as its secretary.

To represent Mexico, President Diaz sent Romulo Escobar, Manuel A. De Quevedo and Carlos Sollier. Señor Escobar, who heads the delegation, is one of the foremost authorities in Mexico on the agriculture of the country. He has been at different times minister of the Department of Agriculture and of the Department of Forestry. With his brother he edits the farm paper *El Agricultor Mexicano*, and he presented a paper on "Agriculture in Mexico" at the time of the St. Louis exposition. Señor De Quevedo is the present minister of forestry. The conference is open to members of the Cabinet, and is shared in by all members of the National Conservation Commission.

The foreign delegates have prepared outlines of the conservation movement in their own countries. Early last year the whole of the public timberlands in British Columbia, except what has been leased, was placed in forest reserves. This action was taken to check waste by bringing the care and cutting of timber resources more effectually under government control. The action affected 150,000,000 acres—as much land as was put into all national forests of this country up to 1907. In the Yukon all water-power rights are now granted for only 20 years, and at the expiration of that time their control reverts to the public. President Diaz, of Mexico, is already applying the principles of forestry, and understands fully the benefits to be gained. He is also interested in the improvement

of agricultural methods. Mexico has few large waterways, but has provided for the expenditure of several million dollars for the improvement of internal navigation.

Reports received here concerning recent discussion in the Canadian parliament of President Roosevelt's proposal for coöperation for the conservation of the natural resources of the whole continent indicate that the support of the conservation movement in the Dominion will be nonpartisan. R. L. Borden, leader of the opposition, was as enthusiastic in his support as Sir Wilfrid Laurier, the premier, who expressed his deepest approval of the movement.

Canada has sent to the National Conservation Commission a number of carefully prepared maps which show the present status of the public lands of the Dominion, as well as the distribution of the principal natural resources and the development of its transportation systems. The Canadian authorities have also gathered together and sent to the chairman of the commission a comprehensive collection of government documents bearing on the natural resources of the country. These have been carefully indexed and bound according to subjects for use at the conference.

The first meeting of the committee on coöperation recently appointed by the chairman of the Conservation Commission to block out methods of joint work on the part of the States and of the United States will be held in Washington for the purpose of determining upon some concerted action. No program has as yet been decided upon.

Gifford Pinchot, Chairman of the National Conservation Commission, was chosen chairman of the International Conservation Conference at the first regular session of the conference which met in Washington Feb. 18. In attendance the conference was limited to the commissioners from the three countries participating. A few members of the National Conservation Commission were present in an advisory capacity.

Secretary of State Bacon called the afternoon session to order. Mr. Sydney Fisher, the Canadian Minister of Agriculture, and chairman of the Canadian delegation, placed Mr. Pinchot in nomination, and Mr. Romulo Escobar, chairman of the Mexican Commission, seconded the nomination. No other name was proposed.

At the suggestion of the chairman of the Canadian delegation, the conference agreed to begin its deliberations by hearing statements from the commissioners of the respective countries as to the extent, condition, and regulations governing the resources of those nations. The first subject taken up was Forests, the first statement on which was made by Miguel A. de Quevedo, President of the Mexican Forestry Commission, who is one of the Mexican commissioners. Mr. Quevedo spoke in French. This was followed by a

statement of forest conditions in the United States by Mr. Pinchot. The statement as to Canadian forests was made on the following morning by Commissioner Fisher. Other speakers followed with special papers.

The striking feature of the conference has been the effort to give it a world-wide scope. Anticipating the interest which would naturally be aroused in other countries by the present North American Conference, President Roosevelt believed that it could be made the precursor of a world congress on the same subject. By an *aide-memoire* in January last, the principal governments were informally sounded to ascertain whether they would look with favor upon an invitation to send delegates to such a conference. The responses have so far been uniformly favorable, and the Conference at Washington has suggested to the President that a general conference be called by him. The President feels, therefore, that it is timely to initiate the suggested world conference for the conservation of natural resources, by a formal invitation.

It is intended to have the conference consider a general plan for an inventory of the natural resources of the world and devise a uniform scheme for the expression of the results of such inventory to the end that there may be a general understanding and appreciation of the world's supply of the material elements which underlie the development of civilization. The conference will also probably consider the general phases of the correlated problem of checking and when possible, repairing, the injuries caused by the waste and destruction of natural resources and utilities, and make recommendations in the interest of their conservation, development, and replenishment.

With such a world-inventory and such recommendation, the various producing countries of the whole world would it be believed be in a better position to coöperate, in the safeguarding and betterment of their common means of support. As was said by the President in the preliminary *aide memoire*, "the people of the whole world are interested in the natural resources of the whole world, benefited by their conservation, and injured by their destruction. The people of every country are interested in the supply of food and of material for the manufacture in every other country, not only because these are interchangeable through processes of trade but because a knowledge of the total supply is necessary to the intelligent treatment of each nation's share of the supply."

Capital expenditure, according to Hugh F. Marriott, should include only the cost of the property and the cost of equipment. If more ground is acquired or additional equipment installed so as to increase the output, then these should be added to the capital-expenditure account.

Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Superheated Steam for Winding Engines

The statement in "Colliery Notes" in the JOURNAL for Oct. 24, 1908, to the effect that at a large English colliery by using superheated steam the number of winds had been increased from 60 to 70 per hour, giving an increased output of 400 tons per day, is of great interest and importance. When it was first introduced superheating was not always successful, and even now is not always successful. As in so many other cases, some engineers who adopted superheating, in the early days of its introduction, omitted to consider one important factor, the temperature of the steam with which they had to deal.

REASON FOR USING SUPERHEATED STEAM

Superheating was introduced to overcome the losses arising from cylinder condensation, and the winding engine affords probably one of the extreme cases. Assume that the steam enters the cylinder at a pressure of 120 lb. per sq.in. and at 350 deg. F., and is cut off, say, at half-stroke. Assume also, for simplicity, that the steam issues from the exhaust at atmospheric pressure, or at a temperature of 212 deg. F. The cylinder walls closely follow the changes of temperature in the steam, and a good deal besides happens in consequence. The winding engine stands, for a certain time, after each wind, and during that period, the engine is cooling and fairly quickly, too, by conduction, radiation, and convection. So that before the commencement of the next wind, the temperature of the cylinder will probably be several degrees below that of the exhaust steam. It may quite easily, in certain cases, be as low as 150 deg. F. The entering steam, at the commencement of the next wind being at a temperature of 350 deg. F., finds itself in the presence of a large mass of metal at, say, a temperature 200 deg. F., or lower. The large mass of metal comprising the engine cylinder is in metallic, and, therefore, thermal-conductive, connection with the large mass of the winding drum and with the rope, which also carries off some heat. As a result, the steam which enters the cylinder at the commencement of the first stroke is cooled very considerably, and the steam which enters the cylinder at each of the working strokes after the first few is also cooled to a certain extent, although not so much as that which enters at the commencement of the wind.

And now comes in another important, though rather a complicated, series of phenomena. We are accustomed to the three states of matter, the solid, the liquid, and the gaseous, but there is also a fourth condition into which many substances may enter, viz., that of vapor. Steam is a gas, and behaves as a gas. Water vapor is not a gas, and does not behave as a gas. Gases have the property of carrying a certain quantity of the vapors of certain substances. Steam, therefore, has a capacity for absorbing the vapor of water, the capacity increasing with the temperature. In the operation of the steam boiler a certain amount of water vapor is formed, and this is carried along by the steam. There is also a certain mechanical action going on in the steam boiler that results in the formation of minute globules of water; these are also carried over with the steam and add to the trouble. Consequently, the steam which enters the cylinders carries with it a certain quantity of the vapor.

The saturation curve for steam with vapor is steep between 200 and 350 deg. F.; so a large portion of the vapor is deposited upon the comparatively cold surface of the cylinder walls. Later on, this vapor which has been deposited, and which has become liquid, is reconverted, not to vapor, but to steam. In order that it may become steam, however, it must absorb heat from somewhere, and the only source is the steam which remains in the cylinder. This means that the steam, which has probably, by this time, commenced the expansive portion of the stroke, is cooled to a greater extent than simple expansion would cause. And as temperature and pressure go together with all gases, cooling the steam means lowering its pressure, and this means the lowering of the mean pressure against the piston.

BENEFITS OF USING SUPERHEATED STEAM

I believe that it has not been possible in winding engines to use a very high expansion, but in all engines expansion is carried on to as great an extent as possible. The pressure of the steam is falling from the moment the entry valve is closed, and, therefore, the mean pressure is always less than the boiler pressure. Assuming a cut-off at half-stroke, the mean pressure behind the piston would be about 115 lb. per sq.in., and with a cut-off at one-third the stroke, about 94 lb. per sq.in. The temperature of steam at 115 lb. per sq.in. is 347 deg. F., and at 95 lb., 334 deg. F. Assume, for the sake of

calculation, that the mean temperature of the steam throughout the stroke is reduced 20 deg. F. With a cut-off at one-third the stroke, the mean pressure would be reduced to about 65 lb. per sq.in., or approximately a loss of 30 per cent. in the power obtained from the engine. With greater expansion, the loss would be greater.

The benefit of superheating is that it converts the vapor which comes over with the steam, and also any water that may be held in mechanical suspension, into steam, and any superheater or system of superheating, is efficient, exactly in the proportion that it accomplishes this. While steam which carries water vapor with it deposits that vapor upon the comparatively cold surfaces of the cylinder walls, superheated or "dried" steam is merely cooled to a certain extent and loses a certain amount of its pressure, and if the superheating is great enough the steam does not condense. Therefore, with properly superheated steam entering the cylinder, considerably more work should be done because, as there is no condensed steam to reabsorb heat at a later period of the stroke, there is less loss of heat energy.

One caution, perhaps, is necessary. Engineers sometimes imagine that applying superheat, in any way and to any extent, will cure the evils of cylinder condensation. Superheating is only effective, and economy only results when the vapor carried by the steam is completely converted into steam.

SYDNEY F. WALKER.

Bath, England, Dec. 29, 1908.

Windy Shots in Coal Mines

The most common cause of coal-mine explosions is usually attributed to blown-out or windy shots which have been tamped with fine coal or dust by a careless miner; as a matter of fact, no miner with a minimum of intelligence, ever thinks of tamping his hole with fine coal or dust without first thoroughly wetting it, for he knows very well that dry coal or dust as tamping would not adhere or pack around his needle sufficiently tight to allow the squib unrestricted passage to the cartridge.

I am aware that in many places the indiscriminate use of a blasting barrel is permitted, which practice cannot be too severely condemned, because it engenders gross carelessness in tamping the hole, this fact often furnishing the means of

a blowout shot. When a needle is used, conditions are different, because the miner must be careful in tamping his hole lest the same become clogged in withdrawing the needle thus preventing his squib from igniting the powder; in this latter case, the miner knows that he may have to drill out his hole and try it again.

Fine coal or dust that has been thoroughly moistened and used for tamping, never was and never will be the means of conveying a flame beyond the mouth of the hole. We sprinkle the mine to keep down the dust, the object being to prevent it from circulating with the air, and to render it less liable to ignition from any cause; the purpose is accomplished when the dust has been sprinkled thoroughly. The miner wets his fine coal for tamping, not with a view of preventing it from flaming, but because he knows that it would be worthless to him as tamping in a dry condition.

AN UNUSUAL EXPERIENCE

That shots are an important factor in coal-mine explosions is too evident to be slighted even for a moment, but that the miner is invariably at fault in placing the blame where it does not always belong. In corroboration of this fact I will relate the following experience I had while managing a coal mine for a well-known Western company: The third level of this mine had advanced about 3000 ft. from the slope, and two practical miners were working in the entry face. One day they fired a shot as usual and immediately afterward repaired to the face to load the coal it broke down; the shot was an ordinary one, having just enough powder to do the work required. A few moments after the shot had been fired and while the drivers and other laborers were gathered on the entry near the slope, a gust of wind having the force of a cyclone hurled them in all directions, extinguished their lights and filled the place with dust from the roof and sides until they were almost suffocated, producing consternation in their minds and causing them to believe their hour of doom had come.

Two gas-watchmen were in the level above and having distinctly heard and felt the shock, at once concluded that an explosion had occurred somewhere in the mine. They hastened to the third level and an investigation was immediately begun to ascertain what damage, if any, had been done, and to discover if possible the cause of this unusual disturbance.

Here were all the characteristics of an explosion, save that there was no flame; the miners in the rooms along the entry had the same experience as the drivers and laborers, all had felt and heard the shock, which extinguished their lights and threw them to the floor. We learned that none of the miners had fired

recently and all declared that the wind had come from the direction of the entry face. Accordingly we went on to the entry face and found the two miners there busily engaged loading their coal into a car. We questioned them closely and examined the effects of the shot carefully and saw no reason why such a commotion should result from a commonplace shot such as this one proved to be. The only solution we could arrive at was that the shot in question had in some manner created an air wave which had traveled against a strong current until it reached the slope where its force was spent in the larger area of the mine.

Had there been standing gas anywhere along the entry or in the rooms, an explosion must have occurred the moment it was carried by this wave in contact with an open light. This phenomenon, if such it might be called, occurred many times afterward, always from the entry, and always having the same characteristics, the entry miners at no time noticing anything unusual at the time the shot was fired.

A PRACTICAL SUGGESTION

A burglar, it is said, sometimes spreads a blanket over a safe before he blows or cracks it, his idea being to deaden the noise made by the explosion as much as possible; if he has the correct idea, then why should we not carry this idea into our coal mines, and hang a heavy curtain or door near the entry face the same to be tightly closed just before a shot is fired. The recent disaster at Marianna is said to have originated from a windy shot in the face of one of the Blanche entries; had a curtain or a door been suspended between the last crosscut and the entry face I venture to assert that the shot in question would not have occasioned any serious trouble.

My experience has been that a windy shot is liable to occur at any time regardless of what kind of tamping is used, and since they are bound to happen, we should endeavor to devise some means to prevent them from spreading the least possible distance from their source.

D. G. THOMAS, Supt.

Evanston Coal Company.

Evanston, Wyoming.

Jan. 25, 1909.

The Gordon Drill

Recently I have learned that the makers of both the Murphy and Waugh drills, who are using "vanadium steel" for the hammers in the drills, have found that it is not necessary to drill the centers out of the hammer, as vanadium steel can be made to take the desired temper *all the way through*. No other steel will do this.

The few of us who know of the break-

ing of the drills, which I mentioned in previous correspondence, are greatly puzzled over the peculiar action of the steel. I have thought that there might be such a thing as a "critical point" in the fatigue of steel; that is, if the weight and number of blows were increased or decreased slightly the steel, in this instance in the shape of drills, would "stand."

While the shapes of the hammers vary

AVERAGE TYPE OF HAMMER IN WHICH VANADIUM STEEL IS EMPLOYED

somewhat in the different makes of hammer drills, the accompanying sketch shows about the average type of hammer when vanadium steel is used.

W.

Denver, Colo., Jan. 31, 1909.

According to the report of the Secretary for Mines the tin ore raised in Tasmania for the quarter ending Sept. 30, 1908, was 1187 tons, valued at £111,004, against 1035 tons valued at £101,626, for the quarter ending June 30, 1908.

Questions and Answers

Inquiries for information are answered in this department as promptly as possible, but more or less delay is often unavoidable. Many inquiries involve a good deal of investigation and these can be answered only when the general interest in the subject is conceived to justify the expenditure of the time required. Correspondents should refrain from asking for advice that ought to be obtained by professional consultation with an engineer. We will not answer questions pertaining to the value of specific mining enterprises. Inquiries should be framed concisely.

PLACERS

What valuable metals other than gold are found in placers?

R. S.

Chiefly tin and platinum. Metallic copper is found in certain placers in Alaska.

MONAZITE

What is the value of monazite sand?

R. S.

This varies according to the percentage of thorium, which ranges from five to seven in the ordinary commercial sand. The American production in 1907 was valued at 12c. per lb.

SHORTHAND BY MACHINERY

What is the address of the maker of the machine for taking shorthand notes that was described in the JOURNAL of July 11, 1908?

F. H.

Address, The Stenotyper Shorthand Machine Company, 105 New Bond street, London, W.

MEERSCHAUM IN THE UNITED STATES

Is any meerschaum mined in the United States? Who are buyers of the mineral?

O. F. R.

So far as we are aware no meerschaum has been produced in the United States. The Meerschaum Company of America, 25 Broad street, New York, is reported to own a deposit in the Alunogen district, Grant county, N. M. Dana reports the occurrence of meerschaum in Utah and at Webster, N. C. The purchasers of meerschaum are the manufacturers of smoking pipes. William Demuth & Co., 507 Broadway, New York, is an important concern.

VALUE OF ALLANITE

What is the market value of allanite? Who buys it?

C. McW.

The value of allanite depends upon the content of thorium oxide, which is very variable; so much so, that the mineral is not commonly regarded as a source of thorium. Sufficient cerium oxide is obtained as a by-product from monazite sand to prevent allanite from becoming a source of that oxide. The Welsbach Incandescent Lighting Company, Gloucester, N. J., would probably be interested in examining samples of allanite.

HYDROMETALLURGICAL EXTRACTION OF COPPER

Are there any plants in successful operation recovering copper directly from its

ore by roasting, lixiviation and precipitation? If so, please give a brief description of the plant, quality of ore treated, and results obtained.

A. B. W.

Such a process, with electrolytic precipitation, employed in Poland, was described in a recent number of the JOURNAL. The Henderson process for burned pyrites is in constant use at Natrona, Penn. See *The Mineral Industry*, Vols. VIII and IX.

WEIGHING GOLD AND SILVER

In the buying and selling of fine gold and silver on the large scale, what difference is permitted, commercially, between the weights of the buyer and the seller, arising from small discrepancies between the scales used by each one and the variation arising from differences in latitude and altitude? What differences is it customary to accept in the marketing of the precious metals at New York?

F. R.

The weights of the buyer are always taken, though the shipper has a right to be represented, and in case he is not satisfied with the weights rendered he may arrange for a referee who will weigh them on scales mutually accepted and this result be final. In selling silver in London less than $\frac{1}{4}$ oz. is disregarded; for instance, should the scale weight show 1000.37 the return would be 1000.25 oz. If the weight were 1000.15 the weight reported would be 1000 ounces.

MEERSCHAUM

What is meerschaum, where is it found, and what are its uses?

A. G. M.

Meerschaum, or sepiolite, is the hydrated silicate of magnesium, containing varying amounts of water and frequently having some of the magnesium replaced by the oxides of iron, copper or nickel. $H = 2$ to 2.5; sp. gr. = 2 [Dana].

It is found in Greece and Asiatic Turkey; in the United States deposits have been discovered in Utah, North Carolina and New Mexico. The Utah and North Carolina deposits are said to be idle, but the Meerschaum Company of America, 25 Broad street, New York, is working the deposit in Grant county, New Mexico.

The meerschaum is found admixed with calcite and other impurities, and these are removed by dry concentration. The finely divided meerschaum is then pressed into blocks or other forms at a temperature of 1080 deg. C., and under certain secret conditions.

The largest use for meerschaum is in the manufacture of smoking pipes. The New Mexico variety is also used to make poker chips, toilet articles, and backs of mirrors.

GAYLEY DRY BLAST

Will you name the blast-furnace plants at which the Gayley dry blast has been installed?

W. F. C.

The following companies have installed

the Gayley dry blast. The first figure given represents the number of furnaces equipped, and the second the year started: United States Steel Corporation, Isabella furnaces, Etna, Penn., 2, 1904; South Chicago Furnaces, South Chicago, Ill., 3, 1908; Warwick Iron and Steel Company, Pottstown, Penn., 2, 1906; E. G. Brooke Iron Company, Birdsboro, Penn., 1, 1906; Guest, Keen & Nettelfolds, Ltd., Cardiff, Wales, 2, 1907; total furnaces in operation, 10.

The following have plants under construction: Toledo Furnace Company, Toledo, O., 2 furnaces; N. W. Iron Company, Mayville, Wis., 2; Pioneer Iron Company, Marquette, Mich., 2; Thyssen, Deutscher Kaiser Works, Germany, 2 (also Bessemer plant); total under construction, 7.

Additional licenses have been sold to the following: Youngstown Sheet and Tube Company, Youngstown, O., 2 furnaces; Federal Furnace Company, Chicago, Ill., 2; Brier Hill Iron and Coal Company, Youngstown, O., 1; Hamilton Iron and Steel Company, Hamilton, Ont., 2; total additional licenses, 7. This gives a total of 24 furnaces equipped, in course of equipment, and licensed.

FLOATED BARYTES

Please give me some information regarding the grinding and floating of barytes. What is the best machinery to use for reducing the mineral to an impalpable powder?

A. L. F.

There are two methods in use for the preparation of barytes for the market. The first method involves crushing the mineral to from $\frac{1}{4}$ to $\frac{3}{8}$ in. size, bleaching, drying, and then reducing to an impalpable powder in bur mills. The other method involves preliminary crushing in a rock breaker, reduction to an impalpable powder in bur mills or tube mills, bleaching and drying. In the second process the mineral is usually crushed wet, and when the final product is classified by floating, it is referred to as "floated" barytes.

The essential machinery for producing floated barytes includes crusher, tube mill, bleaching tank of wood or vitrified brick, classification tank, and dryer for the bleached and floated material. Bur mills may be substituted for tube mills, but in this case the crusher should be followed by rolls.

The operation of drying the floated material often presents many difficulties. As far as we know, rotary dryers give about as good results as any other kind. This part of the work must be carried on carefully, for the bleached mineral is liable to become discolored; the cause of the trouble is often hard to determine. Details of the methods used at different plants are not easy to secure, as most works operate behind closed gates.

Regarding the makers of the machinery required, reference should be made to the advertising pages of the JOURNAL.

Patents Relating To Mining and Metallurgy

A Selected and Classified List of New Inventions Described during the Past Month in the Publications of the Patent Offices

UNITED STATES AND BRITISH PATENTS

A copy of the specifications of any of these patents issued by the United States Patent Office will be mailed by THE ENGINEERING AND MINING JOURNAL upon the receipt of 25 cents. British patents are supplied at 40 cents. In ordering specifications, correspondents are requested to give the number, name of inventor and date of issue.

ALUMINUM

ALUMINUM SILICATE—Method of Treating Aluminum Silicate. Frank J. Tone, Niagara Falls, N. Y., assignor to the Carborundum Company, Niagara Falls, N. Y., a Corporation of Pennsylvania. (U. S. No. 906,173; Dec. 8, 1908.)

SOLDERING—Improvements in Soldering Aluminum. Thomas Harden. Fulham, and Amalgam, Limited, London. (Brit. No. 26,932 of 1907.)

SOLDERING—Improvements in the Method of Soldering Aluminum. Albert Nielson, Nedre Strandgade, Brageønes, Drammen, Norway. (Brit. No. 5055 of 1908.)

WELDING—Improvements in Welding or Melting Objects of Aluminum. Max U. Schoep, Garene-Colombes, France. (Brit. No. 24,283 of 1907.)

BORAX

PROCESS OF MAKING BORAX. Gilbert E. Bailley, Los Angeles, Cal., assignor of one-half to Archie Stevenson, Los Angeles, Cal. (U. S. No. 911,695; Feb. 9, 1909.)

CHROMIUM

PRODUCTION FROM FERRO CHROMIUM—Process for the Production of Pure Chromium from Commercial Ferro-Chromium. Emillen A. O. Viel, Paris. (Brit. No. 24,875 of 1907.)

COAL AND COKE

BRIQUETTING—Method of Briquetting Carbonaceous Materials. Walter T. Griffin, Limoges, France; James Eddy Blake, Isabelle S. Graves, and Charles H. Clarke, executors of said Walter T. Griffin, deceased. (U. S. No. 905,693; Dec. 1, 1908.)

COAL CUTTING—Improvement in, or Relating to Machinery for Cutting Coal. Hubert V. Neukirch and Ernst E. Freytag, Zwickau, Germany. (Brit. No. 10,946 of 1908.)

COAL-CUTTING MACHINES—Improvements in Mechanism for Driving Coal-Cutting Machines. Anderson, Boyes & Company, Ltd., Motherwell, Scotland. (Brit. No. 19,110 of 1908.)

COKE—An Improvement in Coke Quenching Apparatus. Aktiengesellschaft für Kohlendestillation, Gelsenkirchen-Balme, Germany. (Brit. No. 18,110 of 1908.)

COKE-DRAWING APPARATUS. Charles M. Clarke, Pittsburg, Penn. (U. S. No. 907,681; Dec. 22, 1908.)

COKE OVENS—Door for Coke Ovens or Furnaces. John Whitaker, Newhaven, Penn. (U. S. No. 912,218; Feb. 9, 1909.)

COKE OVENS—Horizontally-Moving Leveling-Rod for Horizontal Furnaces. Heinrich Köpfer, Essen on the Ruhr, Germany. (U. S. No. 907,818; Dec. 29, 1908.)

COKE OVENS—Improvements in, and Relating to Coke Ovens. Victor B. F. Fleischl, Douai, France. (Brit. No. 28,049 of 1907.)

COKE OVENS—Improvements in and Relating to Coke Ovens for the Recovery of By-products. Theodor von Bauer, Berlin. (Brit. No. 28,290 of 1907.)

CONVEYING—Improvements in, and Relating to Appliances for Carrying Coal or Other Minerals from the Headlines, Rooms, Walls or Excavating Tunnels of Mines to the Hutches. Thomas P. Neilson, Conbridge, Scotland. (Brit. No. 3193 of 1908.)

RESPIRATION APPARATUS for Use in Coal-Mines and other Places. William E. Garforth, Northampton, England. (U. S. No. 911,389; Feb. 2, 1909.)

COPPER

ELECTROLYTIC REFINING—Process for the Electrolytic Refining of Copper. Joseph

Awallow, St. Petersburg, Russia. (Brit. No. 26,829 of 1907.)

PYRITIC ORE TREATMENT—Improvements in Treating Pyritic Copper and Nickel Ores. James T. Carrick and Basil S. Pattison, Johannesburg, Transvaal. (Brit. No. 296 of 1908.)

PYRITIC SMELTING. James T. Carrick, Johannesburg, Transvaal, assignor of one-half to Basil Stuart Pattison, Johannesburg, Transvaal. (U. S. No. 912,540; Feb. 16, 1909.)

GOLD AND SILVER

AMALGAMATOR. William F. Bedell, North Yakima, Wash. (U. S. No. 907,443; Dec. 22, 1908.)

AMMONIA-CYANIDE PROCESS of Treating Ores Containing Precious Metals. David Mosher, San Francisco, Cal., assignor to Ammonia Cyanide Engineering Company, San Francisco, Cal., a Corporation of California. (U. S. No. 911,254; Feb. 2, 1909.)

CYANIDE PROCESS—Improvements Connected with the Recovery of Gold by the Cyanide Process, and with other Chemical Processes Wherein Zinc is Employed. Edward H. Strange, Charles A. Pim and Francis E. Matthews, London. (Brit. No. 7211 of 1908.)

ELECTROMAGNETIC STAMP-BATTERY. James P. Lynn, Trefalgar, Kalgoolie, Western Australia. (U. S. No. 910,834; Jan. 26, 1909.)

IRON AND STEEL

ALLOYS—Improvements in the Manufacture of Steel Alloys. Jack R. Crawford, Pasadena, Cal. (Brit. No. 21,356 of 1907.)

BASIC BESSEMER PROCESS—An Improvement in the Basic Bessemer Process. Louis P. J. A. H. Messier, Lille, France. (Brit. No. 8168 of 1908.)

BLAST-FURNACE. Joseph E. Johnson, Long Dale, Va. (U. S. No. 906,717; December 15, 1908.)

BLAST-FURNACE CASTING APPARATUS. Michael Killen, Bradford, Penn. (U. S. No. 912,588; Feb. 16, 1909.)

BLAST-FURNACE GASES—Centrifugal Apparatus for the Purification of Blast Furnace, Generator and Other Gases. Communicated from the Société Anonyme John Cockrill, Seraing, Belgium. (Brit. No. 13,563 of 1908.)

BLAST-FURNACE PRACTICE—Method of Effecting the Precipitation of Fine-Dust in Blast-Furnaces and of Preventing the Formation of the Same. Ralph W. H. Atcherson and William Suddall, Leilaire, Ohio. (U. S. No. 912,641; Feb. 16, 1909.)

CASTING PIPE—Mode of Casting Sill, Water and Gas Pipe Direct from the Blast-Furnace in Permanent Molds. Edgar A. Foster, Philadelphia, Penn. (U. S. No. 904,759; November 24, 1908.)

CASTING PLANT. William J. Patterson, Springdale, Penn., and Albrecht B. Neumann, Chicago, Ill. (U. S. No. 912,406; Feb. 16, 1909.)

CHARGING BLAST-FURNACES—Improvements in and Relating to Charging Apparatus for Blast Furnaces and the Like. Allgemeine Elektricitäts Gesellschaft, Berlin. (Brit. No. 4969 of 1908.)

CUPOLA CARBUMPING MECHANISM. James Hyslop, Harvey, Ill., assignor to Whiting Foundry Equipment Company, Harvey, Ill., a Corporation of Illinois. (U. S. No. 911,723; Feb. 9, 1909.)

INGOT STRIPPER. Henry Aiken, Pittsburg, Penn. (U. S. No. 905,827; Dec. 8, 1908.)

MANUFACTURE—An Improved Process for Manufacturing Steel From Chromiferous Pig Iron. Frank D. Curney, Steelton, Penn. (Brit. No. 16,693 of 1908.)

MANUFACTURE—Process of Manufacturing Iron and Steel. Carleton Ellis, White Plains, N. Y. (U. S. No. 911,870; Feb. 9, 1909.)

ORE TREATMENT—Process of Treating Iron Ore. Charles B. Morgan, Cal. (U. S. No. 910,707; Jan. 26, 1909.)

RECEIVER FOR MOLTEN METAL. Harry H. Campbell, Steelton, Penn. (U. S. No. 907,690; Dec. 22, 1908.)

REDUCTION PROCESS—Process of Reducing Ores. George L. Fogler, Pittsburg, Penn., assignor to Fogler Heat and Reduction Company, Tacoma, Wash., a Corporation of Washington. (U. S. No. 908,234; Dec. 29, 1908.)

ROLLING MILLS—Roll for Rolling Mills. Evan Williams, New Castle, Penn. (U. S. No. 907,930; Dec. 29, 1908.)

TUYERE for Blast-Furnaces and Converters. Cyrus Robinson, Mount Vernon, N. Y. (U. S. No. 911,614; Feb. 6, 1909.)

MAGNESIUM

CASTING—Preparing Magnesium and Alloys Thereof for Casting. Paul Rakowicz, Griesheim-on-the-Main, Germany, assignor to Chemische Fabrik Griesheim-Electron, Frankfurt-on-the-Main, Germany. (U. S. No. 906,820; Dec. 15, 1908.)

RARE METALS

THORIUM—Art of Treating Ores. Robert McKnight, Pittsburg, Penn. (U. S. No. 912,485; Feb. 16, 1909.)

TITANIUM ALLOYS—Process of Making Titanium Alloys. Frederick M. Becket, Niagara Falls, N. Y., assignor to Electro Metallurgical Company, New York, N. Y., a Corporation of West Virginia. (U. S. No. 910,894; Jan. 26, 1909.)

TIN

DETINNING—Apparatus for Detinning Tin-Scrap. Meredith Leitich, Elizabeth, N. J., assignor by mesne assignments, to Metal Process Company, a Corporation of New York. (U. S. No. 906,723; Dec. 15, 1908.)

DETINNING—Improvements in, or Relating to Apparatus for Removing Tin from Tin Plate Waste. Dr. Heinrich Brandenburg, Kempen-on-Rhine, Germany. (Brit. No. 2222 of 1908.)

ZINC

EXTRACTION PROCESS—Improvements Relating to the Extraction of Zinc from Ores by the Precipitation Process. Antoine H. Inbert, Grand-Montrouge, Seine, France. (Brit. No. 13,492 of 1908.)

SEPARATION—Improvements in the Separation of Zinc from Its Ores and Compounds. Weldemar Hommel and Henry L. Sulman, London. (Brit. No. 23,901 of 1907.)

MINING—GENERAL

BOLTING—A Method of Consolidating Water Bearing Sands in the Staking of Bore Holes. Compagnie des Mines de Béthune, Les de Calais, France. (Brit. No. 28,541 of 1907.)

EXCAVATING AND LOADING MACHINE. Joseph Bingham, Garrett, Kan., assignor of one-half to George W. Hunley, Garrett, Kan. (U. S. No. 909,928; Jan. 19, 1909.)

EXCAVATING SHAFTS, ETC.—Process for Excavating Shafts, Tunnels and the Like. Friedrich Koepe, Bochum, Germany. (Brit. No. 29,788 of 1908.)

MINING METHOD—Method of Minning. William G. Anderson, Smuggler, Colo. (U. S. No. 906,765; Dec. 15, 1908.)

PROPS—Improvements in Mining Props. John H. Ekershoff, Düsseldorf, Germany. (Brit. No. 22,223 of 1908.)

SIGNALING—Improvements in Signaling Systems for Mines and the Like. George T. Plumb, Johannesburg, Transvaal. (Brit. No. 10,104 of 1908.)

TIMBERING—Improved Method of Walling, Timbering and Proping Mines. Friedrich Nellen, Essen on the Ruhr, Germany. (Brit. No. 14,273 of 1908.)

VENTILATING SYSTEM for Mines. John Quin, Houtzdale, Penn. (U. S. No. 911,525; Feb. 2, 1909.)

ORE DRESSING

AGITATOR. David H. Sherman, Los Angeles, Cal. (U. S. No. 912,628; Feb. 16, 1909).

CLASSIFIER. Charles W. Merrill, Lead, S. D. (U. S. No. 907,387; Dec. 22, 1908).

CONCENTRATOR—Apparatus for Concentrating Ores, Walter M. Sanders, Marion, Ky. (U. S. No. 911,077; Feb. 2, 1909).

CONCENTRATION—Improvements in Ore Concentrating and Separating Apparatus, Francis and Henri Dallenage, Passages, Bretagne, France. (U. S. No. 908,449; Dec. 29, 1908).

CONCENTRATING-TABLE. Willis G. Dodd, San Francisco, Cal. (U. S. No. 908,758; Jan. 5, 1909).

CONCENTRATORS—Actuating Mechanism for Concentrators, William L. Card and Frank S. Card, Denver, Colo., assignors to the Card Manufacturing Company, Denver, Colo., a Corporation of Colorado. (U. S. No. 907,736; Dec. 23, 1908).

DISINTEGRATING APPARATUS—Apparatus for Disintegrating Ores and Other Materials, Harry W. Harding, New York, N. Y. (U. S. No. 908,861; Jan. 5, 1909).

ELECTROMAGNETIC ORE-SEPARATOR. Thomas Charlton, Chicago, Ill., assignor of right to Robert L. Dornan and one-fifth to James H. Parker, El Paso, Tex. (U. S. No. 912,363; Feb. 16, 1909).

FLOTATION PROCESS—Apparatus for Separating Ores by Flotation, Auguste J. F. de Bayay, Kew, Victoria, Australia. (U. S. No. 912,497; Feb. 16, 1909).

GRINDING—Improvements in Grinding Machines for Minerals and Other Substances, Lawrence S. Burt, Logdon. (Brit. No. 8955 of 1908).

GRINDING MILLS—Improvements in Grinding Mills, Joseph B. Alentown and William J. Montz, Ormrod, Penn. (Brit. No. 14,398 of 1908).

MAGNETIC SEPARATION—Improvements in, and Relating to Magnetic Separating Machines, The Empire Magnetic Machine Company, Ltd., Herbert H. Thompson and Alfred E. Davies, Birmingham, Eng. (Brit. No. 2203 of 1908).

ORE-CONCENTRATOR. Ulysses S. James, Newrick, N. J., assignor, by direct and mesne assignments, to James O. Concentrator Company, a Corporation of New Jersey. (U. S. No. 906,433; Dec. 8, 1908).

ORE-FEEDER. Thomas M. Topp, San Francisco, Cal. (U. S. No. 910,097; Jan. 19, 1909).

ORE-GRINDING MACHINE. George A. Henny, London, England. (U. S. No. 900,286; Jan. 12, 1909).

ORE SEPARATION—Improvements in Ore Separating Processes, Marcus Rutenburg, Lockport, N. Y. (Brit. No. 28,191 of 1907).

ORE SEPARATORS—Improvements in Centrifugal Ore Separators, Philip F. Peck, Chicago, Ill. (Brit. No. 3683 of 1908).

ORE-TREATING MACHINE. John W. R. Tuxton, Lynn, Mass. (U. S. No. 909,429; Jan. 12, 1909).

SCREEN—Oscillating Screen for Ore and Other Materials, Albion B. Colcord, Kokomo, Colo., assignor to Robert B. McConney and Charles L. Buckingham, Denver, Colo. (U. S. No. 911,113; Feb. 2, 1909).

SCREEN—Rotary Screen for Ores and Other Materials, Howard G. King, Denver, Colo. (U. S. No. 905,325; Jan. 1, 1908).

SEPARATION—Improved Apparatus for Separating Metals and the Like from Extraneous Matter, Charles M. Simpson, Wellington, N. Z. (Brit. No. 16,863 of 1908).

SEPARATION PROCESS—Improvements in Apparatus for More or Less Completely Separating Subdivided Solid Matter from a Liquid, Particularly Applicable for Thickening Ore Pulp and for Feeding or Measuring the Pulp or Solid, Francis E. Elmore and Alexander E. Elmore, London. (Brit. No. 26,821 of 1907).

STAMP MILLING—Improvements in Ore Feeders for Stamp Mills and the Like, Arthur H. P. Fitzpatrick, Chester, Eng. (Brit. No. 14,555 of 1908).

METALLURGY—GENERAL

ALLOY of Iron and Nickel with Vanadium Carbide, Walter H. Hubel, Germany. (U. S. No. 906,937; Dec. 15, 1908).

ORE ROASTING—Method of Roasting Ores, Henry K. Hess, Philadelphia, Penn. (U. S. No. 912,568; Feb. 16, 1909).

SMEETING—Improvements in the Metallurgical Treatment of Ores and Other Materials, Kristian Birkeland, Christiania, Norway. (Brit. No. 913 of 1908).

MINING MACHINERY AND APPARATUS

BORE HOLES—Device for Ascertaining the Deviation of Bore Holes, Louis Gerhardt

Northhausen, Germany. (Brit. No. 11,628 of 1908).

BORE HOLES—Improvements in, or Relating to Device for Determining the Deviations of Bore Holes from the Vertical, Karl Haussmann, Aix-la-Chapelle, Prussia. (Brit. No. 3068 of 1908).

CANDLESTICK—Miners' Safety-Candlestick, Frederick Muenger, Hill City, S. D., assignor of one-half to Camillo von Woehmann, Hill City, S. D. (U. S. No. 906,449; Dec. 8, 1908).

CENTRIFUGAL PUMPS—Improvements in, or Relating to Centrifugal Pumps, James T. Hosier, London. (Brit. No. 21,584 of 1908).

CONVEYER-BELT SUPPORT. Edwin E. Vrooman, Hyattsville, Md., assignor, by direct and mesne assignments, of one-half to John J. Ridgway, Chicago, Ill., and one-half to Edward G. Thomas, Brookline, Mass. (U. S. No. 909,833; Jan. 12, 1909).

CRUSHING MACHINES—Improvements in Machines for Crushing Stone and Other Hard Substances, Saxon Engineering Company, Ltd., Saxon Iron and Steel Works and Edward G. P. Bousfield, Fenton, Eng. (Brit. No. 25,536 of 1907).

DREDGE—Suction-Dredge or the Like, Franklin H. Jackson, Berkeley, Cal., assignor to Byron Iron Works, West Berkeley, Cal., a Corporation of California. (U. S. No. 906,234; Dec. 8, 1908).

DREDGES—Suction Mouthpiece for Dredges, Horace J. Clark, Chicago, Ill., assignor to Chicago Dredge Manufacturing Company, Chicago, Ill., a Corporation of Maine. (U. S. No. 909,062; Jan. 5, 1909).

DRILL-HOLE-CLEANING ATTACHMENT for Hammer-Drills, Daniel S. Waugh, Denver, Colo., assignor to the Denver Rock Drill and Machine Company, Denver, Colo. (U. S. No. 907,430; Dec. 22, 1908).

DRILLING—Core Drilling Apparatus, Coleman A. Terry, New York, N. Y. (U. S. No. 904,161; November 17, 1908).

DRILLS—Improvements Relating to Hammer-Drills, H. H. Rayner, Sheffield, and Cecil Walton, Moresby, Whitehaven, Eng. (Brit. No. 27,371 of 1907).

DRILLS—Improvements Relating to Miners' Drills, The Hardy Patent Pick Company, Ltd., Heeley, and Mark Watwright, Sheffield, Eng. (Brit. No. 16,503 of 1908).

DYNAMITE-HEATER. Alexander H. Vanauker, Hazleton, Penn. (U. S. No. 911,463; Feb. 2, 1909).

MINE-CAR PEDESTAL. John R. Roberts, Wilkes-Barre, Penn. (U. S. No. 905,000; November 24, 1908).

MINERS' CANDLESTICK. Benjamin F. Kelly, Salt Lake City, Utah. (U. S. No. 910,390; Jan. 19, 1909).

MINERS' CANDLESTICKS—Attachment for Miners' Candlesticks, Sanford M. Thurman, Los Angeles, Cal. (U. S. No. 908,821; Jan. 19, 1909).

MINERS' DRINKING CANS—Improvements in, or Relating to Miners' Drinking Cans, Marks Garelick, Cardiff, Wales. (Brit. No. 9252 of 1908).

MINERS' SAFETY-LAMP. Ernest A. Hallwood, Morley, England. (U. S. No. 908,765; Jan. 5, 1909).

PICKS—Improvements in Miners' and Like Picks, Arthur Roughley, Spenmoor, Eng. (Brit. No. 2772 of 1908).

ROCK-DRILL. John H. Huhn, Fairmont, W. Va., assignor of one-half to John R. Sted, Barrsville, W. Va. (U. S. No. 904,436; November 17, 1908).

ROCK-DRILLING MACHINES—Improvements in Rock-Drilling Machines, Henry Ball, John Ball and Robert Arth, Knights, Treanure, (Brit. No. 9084 of 1908).

ROCK-DRILLING TOOL. Hugh G. Williams, Granville, N. Y., assignor of one-half to Samuel F. Culbertson, Baltimore, Md. (U. S. No. 912,925; Feb. 16, 1909).

ROCK DRILLS—An Improved Chuck for Rock Drills, Dickerson, Derby, Bunt, Penzance, Eng. (Brit. No. 25,002 of 1907).

ROCK DRILLS—An Improved Valve for Rock Drills and Analogous Reciprocating Appliances, George H. Rayner, Nether Edge, Sheffield, Eng. (Brit. No. 20,899 of 1908).

SAFETY APPARATUS for Mine-Railways, Norman W. Dickerson, Derby, Ohio. (U. S. No. 911,298; Feb. 2, 1909).

SAFETY-LAMP. Nickotas B. Ippolito, Pittsburgh, Penn. (U. S. Nos. 909,415 and 909,416; Jan. 12, 1909).

SAFETY LAMPS—Igniting Device for Miners' Safety-Lamps, Frederick A. Weice, Barmen, and Rudolf Gartenmeister, Elberfeld, Germany. (U. S. No. 908,432; Dec. 29, 1908).

SAFETY LAMPS—Improvements in Apparatus for Igniting Miners' Safety Lamps,

Ernest A. Hallwood, Morley, Eng. (Brit. No. 25,596 of 1908).

SAFETY LAMPS—Improvements in Apparatus for Igniting Miners' Safety Lamps, Especially Suitable for Use in the Underground Workings of Mines and in the Like Places, Ernest A. Hallwood, Morley, Eng. (Brit. No. 27,140 of 1907 and 24,414 of 1908).

STEAM DRILLING—Steam-Motor for Operating Tools in Drilling Holes, Frank S. Barkedew, Los Angeles, Cal., assignor to the California Steam Drilling Rig Company. (U. S. No. 12,904; Release, Dec. 29, 1908).

TUNNELING-MACHINE. Charles A. Case, New York, N. Y., assignor to Case Tunnel and Engineering Company, New York, N. Y., a Corporation of Arizona. (U. S. No. 910,500; Jan. 26, 1909).

TUNNELING MACHINES—Improvements in Rotary Tunneling Machines, Russell B. Sigafos, Denver, Colo. (Brit. No. 6916 of 1908).

METALLURGICAL MACHINERY AND APPARATUS

ELECTRIC FURNACES—Improvements in, and Relating to Electric Furnaces, Communicated from the General Electric Company, Schenectady, N. Y. (Brit. No. 23,071 of 1908).

ELECTRIC FURNACES—Improvements in, and Relating to Electric Furnaces, Antoine H. Imbert, Grand Montrouge, Seine, France. (Brit. No. 17,281 of 1908).

ELECTRIC FURNACES—Improvements in, or Relating to Electric Furnaces, Charles A. Keller, Paris, France. (Brit. No. 21,741 of 1908).

ELECTRIC FURNACES—Improvements in, or Relating to Electric Furnaces, Hans Wabnitz and Wilhelm Thomsen, Thomsen's Werke Gesellschaft, Berlin. (Brit. No. 7923 of 1908).

FURNACE—Universal Ore-Treating Furnace, Chaucey C. Medbery, New York, N. Y. (U. S. No. 912,394; Feb. 16, 1909).

FURNACE CHARGING MECHANISM. David Baker, Philadelphia, Penn. (U. S. No. 909,049; Jan. 5, 1909).

FURNACE GRATES—Improvements in, and Relating to Furnace Grates, Heinrich Uehdelt, Cassel, Germany. (Brit. No. 23,350 of 1907).

FURNACE GRATES—Improvements in Furnace Fire Grates, Albert Jones and the Trimsaran Company, Ltd., Trimsaran, Kidwellie, South Wales. (Brit. No. 23,208 of 1907).

HOIST FOR FURNACES—Bottom-Door Hoist for Furnaces of Cupolas, James Hyslop, Harvey, Ill., assignor to Whiting Foundry Equipment Company, Harvey, Ill., a Corporation of Illinois. (U. S. No. 911,726; Feb. 9, 1909).

HYDROMETALLURGICAL APPARATUS—Mobile Hydrometallurgical Apparatus, Hiram W. Blaisdell and Joseph R. Brown, Los Angeles, Cal., assignors to Blaisdell & Brown, Los Angeles, Cal., a Corporation of California. (U. S. No. 907,300; Dec. 22, 1908).

MOLD—Water-Cooled Mold for Receiving Supermolten Metal from an Electric Furnace, George O. Seward, Holcombs Rock, Va., assignor to Virginia Laboratory Company, New York, N. Y., a Corporation of New York. (U. S. No. 905,373; Dec. 1, 1908).

ORE TREATMENT—Improvements in, or Relating to the Treatment of Ores for the Extraction of Metals Therefrom, Hugues Reinit, Paris. (Brit. No. 25,357 of 1907).

PRECIPITATING APPARATUS. John E. Greenawald, Denver, Colo. (U. S. No. 906,011; Dec. 8, 1908).

REDUCTION-FURNACE. Charles Van Brunt, Schenectady, N. Y., assignor to General Electric Company, Schenectady, New York. (U. S. No. 905,922; November 17, 1908).

RETORT-FURNACES—Improvements in, or Relating to Retort Furnaces and the Like, Hans Ries, Munich, Germany. (Brit. No. 8270 of 1908).

ROTARY KILN. Maunfred G. Semper, Weferlingen, Germany. (U. S. No. 909,464; Jan. 12, 1909).

SMEETING FURNACE Heated with Oil and Having Two or More Chambers Acting Accurately as Smelting or Preliminary Heating Chambers, (August Hock, Hannover-List, Germany. (Brit. No. 17,687 of 1907).

SMEETING FURNACES—Improvements in, and Relating to Smelting Furnaces, Herbert H. Haveler, Norton Abbey, Eng. (Brit. No. 25,997 of 1907).

TAP-SPOUT for Smelting-Furnaces, Frederick D. Gross, Denver, Colo., assignor of one-half to Colorado Iron Works Company, Denver, Colo. (U. S. No. 910,571; Jan. 19, 1909.)

Personals

Mining and metallurgical engineers are invited to keep *THE ENGINEERING AND MINING JOURNAL* informed of their movements and appointments.

There is a vacancy on the editorial staff of the *JOURNAL* open to a young mining engineer, who should have had some literary experience. Candidates are requested to call in person.

S. W. Mudd has returned to Los Angeles, California.

Wm. C. Ralston, of San Francisco, has been a visitor in New York.

S. F. Shaw, of Pasadena, Cal., is examining mines in Cochise county, Arizona.

J. W. Bryant, of Victoria, B. C., one of the Tyee Copper Company's mining engineers, is in Mexico.

Dr. William B. Phillips, of Birmingham, Ala., is examining iron-ore properties in Llano county, Texas.

E. B. Stahlknecht has established an office as consulting mining engineer at Torreon, Coahuila, Mexico.

John T. Fuller, Little Rock, Ark., has been appointed general manager of the Arkansas Diamond Company.

H. C. Hoover has returned from California and will shortly begin his course of lectures at Columbia University, New York.

Mortimer B. Fuller has been elected president of the International Salt Company, to succeed his father, the late E. L. Fuller.

George Stilwell, superintendent of the Hewitt mine, Silverton, Slocan district, B. C., has gone to England for two months.

Charles Briggs, president of the Calumet & Arizona Copper Company, of Bisbee, Arizona, is seriously ill at his home in Calumet, Michigan.

George M. Bloomer, manager of the Alamos Mines Corporation, Alamos, Sonora, Mexico, is in New York on business connected with the mines.

G. Harold Grant will shortly leave Victoria, B. C., on a professional visit to Japan. He may also go to Korea before returning to British Columbia.

Henry M. Adkinson has returned to Denver from a three weeks' trip of inspection to the properties under his management at Telluride, Colorado.

T. F. Cole, president of the Oliver Iron Mining Company, has been chosen to represent Minnesota on the reception committee to serve at the coming inauguration of President-elect Taft.

Frank Van Orden, superintendent of the Wyandot Copper Company in the Lake Superior district, has returned to the

property after an extended visit to the Globe district in Arizona.

Allan Edyvean, formerly superintendent of the Arcadian stamp mill, has been appointed to take charge of the erection of the new Winona-King Phillip stamp mill in the Lake Superior copper district.

Edward G. Acheson, president of the International Acheson Graphite Company, of Niagara Falls, N. Y., has had the degree of doctor of science conferred upon him by the Western University of Pennsylvania, of Pittsburgh.

H. H. Dyer, for five years past, superintendent of mines of the Shannon Copper Company, at Metcalf, Ariz., has resigned that position, to take effect March 1, and will open an office at Los Angeles, Cal., as consulting mining engineer.

Obituary

Edward Myers, formerly in charge of the Combination Fraction, at Goldfield, and recently operating a mine in the Gold Crater district, shot himself at Goldfield, Nev., Feb. 19, dying in a very short time.

J. H. Blanchard, a prominent mining engineer and operator, of Goldfield, Nev., died suddenly Feb. 11. At the time of his demise, Mr. Blanchard was operating the Combined Mining and Leasing Company, and the Grizzly Bear lease on the Consolidated ground.

John D. Bailey, who died in Pittsburg, Jan. 17, was born in that city in 1826. He was for a number of years connected with the Wayne Iron Works, and had charge at one time of the manufacture of the plates used on the ironclad vessels built for river service during the Civil war. Later he was prominent as an oil operator, and for some time was superintendent of the Chartiers Valley Gas Company. For many years past he had been a member of the Pittsburg Oil Exchange.

Carroll D. Wright died in Worcester, Mass., Feb. 20. Born in New Hampshire in 1830, he received a fair education in local schools. After serving with credit through the Civil war he began the practice of the law in Boston and also served two terms in the State Senate. In 1873 he was appointed chief of the Massachusetts Bureau of Statistics of Labor, and his intelligent and careful work in that position soon attracted attention. Before long his reports on labor questions were accepted as high authority. When the United States Bureau of Labor was established in 1885, Colonel Wright was appointed the first commissioner, and he held the position until 1905, a period of 20 years, during which his work was maintained at the same high standard which had marked it in Massachusetts. At different times he was called on to deliver special courses of lectures at Harvard

University, at Oxford University, at Berlin, Heidelberg and elsewhere. He was also at different times president of the American Statistical Association and the American Association for the Advancement of Science. He was a member of many foreign societies. In 1902-3 he served as a member of the Anthracite Strike Commission, and his influence and advice did much toward securing the settlement reached by the commission. In 1905 Colonel Wright resigned his position as commissioner of labor, and was chosen president of Clark University at Worcester, Mass., but failing health prevented him from taking as active a part in that position as he might otherwise have done. His literary work is found mainly in his yearly reports.

Societies and Technical Schools

Canadian Mining Institute—The preliminary program for the annual meeting at Montreal provides for three sessions on each day of the meeting. On Wednesday, March 3, the morning session will be the business meeting, at which the reports of the officers and council will be presented. The afternoon and evening sessions will be devoted to reading and discussion of papers. On Thursday, March 4, the morning session will be devoted to the reading of papers. In the afternoon there will be one executive session to consider proposed amendments to the by-laws and in the evening a smoking concert.

On Friday, March 5, the morning session will be devoted to papers and discussions; the afternoon to any unfinished business which may remain. In the evening the meeting will close with the annual dinner.

College of the City of New York—Prof. Charles Baskerville, director of the Department of Chemistry, which has excellent laboratory and other facilities, gives notice that a special course in physical chemistry is offered to properly qualified persons. The course which is given by Dr. Leo Frank Guttman, instructor in physical chemistry, involves 15 lectures Wednesday afternoons, accompanied by laboratory practice on Thursdays. The lectures, which begin Feb. 24, will cover the following topics: Introductory and Theoretical Foundations; Changes of State and the Kinetic Theory; Thermal Chemistry; the Phase Rule; Relation between Physical Properties and Chemical Constitution; Solutions and Osmotic Pressure; Atoms and Radioactivity; Faraday's Law and Electrolytic Transport; Influence of Mass and Temperature on the Progress of Reactions; Applications of Dissociation Theory; Electromotive Force. The laboratory work includes experimental verification of the above principles. The only expense attached is the actual cost of chemicals used and breakage.

News of the Industry Reported by Special Representatives at
San Francisco, Goldfield, Salt Lake City, Denver, London and Paris

REVIEWS OF IMPORTANT EVENTS

San Francisco

Feb. 17—The gold-dredging men have taken a leaf out of the hydraulic miner's book by adopting the use of water under pressure through nozzles to break down cemented banks into the dredge buckets and have greatly expedited their work thereby. Indeed, they are now increasing the size of the giants. They at first used 4-in. giants, but are now adopting 6-in. ones. By the use of three-step centrifugal pumps they get about 160 ft. head of water for use against the cemented banks. Two streams are kept playing, one on each side of the digging end of the bucket ladder, and these are moved as the ladder and line of buckets move, so as to play close to the buckets in the banks. The plan is quite effective where the gravel is at all cemented. And now some of the hydraulic miners of Trinity county are going to adopt a dredge to assist their operations. The higher banks will be piped as usual, and, as a supplementary appliance, a dredge will be installed to work the low benches of the hydraulic property. This is quite a concession to the cheapness of dredge work, for hydraulic mining has usually been considered the cheapest method of gaining gold. However, late work of large and heavy dredges is showing a very low cost, especially when the machines are new and repairs not necessary.

E. O. Miller, of Visalia, has brought suit against the Edison Electric Company, of Los Angeles, for damages to his mining claim in the upper Kern river cañon, by the erection of the electric company's big dam. Senator Miller's Hard Rock claim embraces the entire channel of the river and a strip on each side. The dam erected below the claim flooded it to such a depth that mining for gold is no longer possible. Hence the suit.

Attention is again being called to the deposits of chrome iron in Humboldt and Del Norte counties. One large deposit in the latter county was worked years ago and shipments made through Crescent City, but the expense of transportation was found to be too high for profitable working, and nothing has been done for the past 10 years. The deposits are owned by Philadelphia people. There are known to be several good sized deposits in the neighborhood of Bear river and in the Horse mountain copper district, near Willow creek, in Humboldt county. The Bear river deposit appears to be now coming into notice owing to the nearness

of the new shipping point established at the mouth of the Mattole river.

State Senator Caminetti, who, when in Congress was the author of the act establishing the California Débris Commission, has a bill in the legislature which has been reported favorably, in relation to caring for hydraulic mining debris. The bill calls for the appointment of a consulting board of five members to the department of engineering who shall devise plans for preventing debris from mining or other causes from encroaching on navigable streams or the lands adjacent thereto; to select sites for settling reservoirs and storage of debris; to inspect hydraulic mines and pass upon their methods of storing debris; to determine the effect of hydraulic mining carried on by or under permission of the California Débris Commission; to construct restraining barriers and dams and other works as may be authorized by law jointly with the United States government. Three of the members of this consulting board are to be actively engaged in gravel mining in the hydraulic mining regions.

Goldfield, Nevada

Feb. 16—It is reported that George Wingfield is working on a consolidation to include the Booth, Columbia Mountain, Nighthawk, Ethel, Oro, Kewanas and Berkeley companies. The sums in the treasuries of the various companies would give a working capital of over \$70,000 to the merger company, and the property would contain more than 300 acres of mineral ground adjoining the Consolidated on the north.

On March 1 the case between the Goldfield Consolidated and the Frances Mohawk Leasing companies will come to trial before Judge Stevens, of the District Court. The amount involved is \$125,000 and arises from the contention of the Consolidated company that the mining operations of the leasing company were not performed in a miner-like fashion and that the workings were left in a dangerous condition due to the robbing of the mine. When the leasing company deposited \$125,000 in a local bank some time ago, the Consolidated company filed a damage suit and attached the funds, whereupon the leasing company furnished bonds for the release of the same; this was contested in turn by the parent company which questioned the responsibility of the sureties.

A Tonopah miner was arrested in that city last week charged with high-grading

from the Broken Hills mine, where he had been employed. A search of the quarters occupied by the prisoner disclosed about 600 lb. of rock averaging \$3 per pound. High-grading has been suspected by the management for some time, and it is thought that the arrest will lead to the detection of several others similarly implicated.

Ore shipments from Tonopah for the week ending Feb. 13 were: Tonopah Mining Company, 3200 tons; Montana Tonopah, 640; Tonopah Belmont, 700; Jim Butler, 250; MacNamara, 200; Tonopah Midway, 100; and West End 100 tons, having a total estimated value of \$130,000.

A deal was recently closed in the Pioneer district whereby E. S. Giles and W. B. Milliken assume control of the Indiana group. The new owners have started a working shaft about 200 ft. distant from the main shaft of the Pioneer. A hoisting plant will soon be installed. The Mayflower mill is now practically completed and on the arrival of the pump will be placed in commission.

The first dividend to the employees of the Ophir and Consolidated Virginia companies at Virginia City was paid Feb. 11. The dividend, amounting to \$1956, was for the last three months and was divided among the employees according to their wage-earning capacity. This is an innovation in Nevada and its operation will be watched with interest.

Salt Lake City

Feb. 19—The Conkling Mining Company has filed supplemental proceedings in the Federal court against the Silver King Coalition Mines Company. The Conkling affidavit states that the King company shipped 14,400 tons of ore worth about \$40 per ton, or a total of \$576,000, besides 18,720 tons of concentrating ore, which when treated gave 6240 tons of concentrates valued at \$40 per ton or \$249,600. This gives a total gross value of \$825,600. The cost of mining, milling, etc., is given at \$421,440, leaving an alleged net value of \$404,160 said to have been taken from the Elephant stope. The Conkling company, owning three-fourths interest in the ground, in which the Elephant stope is said to be, brings suit for \$303,120. Mr. Treweek states that the Conkling company will sink a three-compartment shaft on the Conkling claim and expects to strike the ore near or over the Elephant stope at a depth of approximately 850 feet.

It is rumored that the United States

Smelting, Refining and Mining Company is trying to purchase the Knight smelter and the Colorado mine at Tintic.

Another test run of the Fink smelter will be made at Garfield as soon as Mr. Fink returns. Heretofore, coal was employed as fuel, but in the coming test oil will be used.

On account of the heavy storms, the Utah Copper Company has been experiencing considerable difficulty in getting ore transported between the mine and the mill at Garfield. The company will probably build a line of its own in the near future.

The annual report of the Ohio Copper Company for the year ending Jan. 1, 1909, which was published this week shows the following: Assets—Development, \$75,151; mine surface equipment, \$33,645; mining properties, \$11,257,625; Columbia shaft, \$38,142; treasury bonds, \$129,000; treasury stock, \$1,797,500; accounts receivable, \$5317; construction concentrator, \$778,034; cash, \$60,540; miscellaneous, \$19,538; total, \$14,194,492. Liabilities—Capital stock issued \$13,000,000; first-mortgage bonds, \$1,000,000; accounts and bills payable, \$194,492; total, \$14,194,492. Authorized capital, 1,500,000 shares; held for conversion of bonds, 200,000 shares; \$2,000,000 bonds are authorized, but only one half issued.

A body of low-grade ore was cut last week by the east drift of the Iron Blossom, about 140 ft. east of the north shaft. A raise from this drift has developed 15 ft. of black carbonate ore, high in lead and carrying considerable silver. This strike in the Iron Blossom made Feb. 15 the biggest day on the Salt Lake Stock Exchange since last June. This stock, which sold at \$2.80 on Feb. 13, went as high as \$3.25, and nearly 25,000 shares were sold. On the same day, 180,000 shares of Tintic Central sold at 20 to 25c. During the day 464,764 shares, having a value of \$199,327, were sold. With the Iron Blossom stock selling at its present price, the property is worth about \$3,200,000.

The Tintic ore shipments for the week ending Feb. 12 were: Centennial Eureka, 46 carloads; Eureka Hill, 5; Yankee, 2; May Day, 2; Eagle and Blue Bell, 1; Bullion Beck, 2; Sioux Consolidated, 15; Iron Blossom, 2; Ajax, 2; Dragon Iron, 23; Colorado, 20; Brooklyn, 6; total, 126 carloads.

Butte

Feb. 18—E. F. Frisbie, president of the Raven Copper Company, in a circular letter to stockholders, has placed the critical position of the company before them and has made a further appeal for subscriptions for the 63,000 shares recently offered. In the letter he states that unless a better showing is made by the stockholders by Feb. 24, the money already subscribed will be returned and the prop-

erty closed down permanently until a plan of reorganization can be perfected. At the continued hearing of the case of Bliss against the Anaconda Copper Mining Company, held before Judge Hunt at Helena last Monday, the possibility of further abating the injurious effects of the Washoe smelter fumes was taken up. Superintendent Matthewson and J. R. Faulding, a chemical engineer from New York City, gave testimony on behalf of the company to the effect that the methods now employed by the smelter were the most advanced known to science and that the installation of any other method would mean the expenditure of several millions of dollars with merely problematical results. Further hearing was adjourned until Feb. 19.

At a recent meeting of directors of the Butte-Montana company, held in Pittsburgh, an offer of Duluth capitalists to finance the company was favorably considered and the plan will now be put up to the stockholders. The plan contemplates the purchase by the Butte Alex Scott company of the property of the Butte-Montana in exchange for 50,000 shares of the former company's stock. The Butte-Alex Scott company is a Delaware corporation with a capital of \$1,250,000, divided into shares of the par value of \$10 each. In addition to giving the Butte-Montana company 50,000 shares of stock the Butte-Alex Scott company will also agree to pay off all indebtedness of the old company.

Deadwood, S. D.

Feb. 20—Notwithstanding the severity of the winter, mining and milling in the Black hills has been little affected. The North Homestake Company has temporarily suspended operations. It is generally reported that a change will be made in the method of ore treatment. The Gilt Edge Maid has also closed down, awaiting the completion of financial arrangements for enlarging the mill. The large slime tonnage handled by the Homestake company is soon to be increased by the addition of two new Merrill presses. The addition being made to the building will accommodate four presses, which should increase the total capacity to above 2000 tons.

The Golden Reward Mining Company is installing Moore filters for the treatment of the slimes. The present treatment is: Gates crusher to rolls, to Chilean and Huntington mills, to classifiers. The sand from the classifiers goes to leaching vats, and slime is treated partly in a Chamberlin press and partly by decantation. In the remodeled mill the slimes will go to a Dorr thickener, from which the underflow will go direct to the Moore filters. Stearns, Roger & Co., of Denver, Colo., are putting in the new equipment. The Moore process of filtration will also

be used in the new mill now under construction for the Golden Crest Mining Company. Here the pulp from the stamps will go to the Dorr classifiers, the sand being reground in tube mills; the tube mill discharge joining the slime overflow from the classifiers, will go to Dorr thickeners, from which the underflow will be agitated by a Gordon worm. The feed from the latter will flow direct to the Moore filters.

Denver

Feb. 20—Work in the tungsten belt in Boulder county seems to be increasing, but operators in general appear to be awaiting the action of Congress on a revision of the tariff, and a hoped-for duty to be imposed on foreign imports of that metal. The fight for the control of the Daly-West mine at Park City, Utah, which has been waged in Denver for some days past, between McCormick, the Salt Lake banker, and his friends, and J. J. Daly, the discoverer, and his friends among the Cincinnati stockholders, has resulted in defeat for the Daly party, and the old management remains in control. Charges and countercharges of mismanagement and fraudulent intent were freely made on both sides. It was stated that there is \$320,000 in the operating fund, and that owing to the low price of silver and lead, no dividend was paid last year—the first time in nine years that a dividend has not been declared.

There is now a good deal of activity in what is known as the Rangely oil district, in Raven Park, Rio Blanco county, and on the projected line of the Denver, Northwestern & Pacific railway, now under construction. Some years ago six test wells were drilled, and oil was struck in several of these wells, which were put down as deep as 2000 ft., and have 200 ft. of oil in them, and of such fine quality that the people in the vicinity burn it in their lamps instead of buying refined oil. Owing to the then uncertainty of a railway, and other causes, work ceased. Now, however, the Gilson Asphalt Company has a drill in there, with a capacity of 6000 ft. depth, and a private syndicate of Vernal, Utah, men has installed a drill with a 2500-ft. capacity, commencing operations on Jan. 19, and are now down 1000 ft. The activity in railway construction in this part of the West is the stimulus for these and many other mining operations.

Indianapolis

Feb. 22—The prospects for a good summer's work at the mines in the Jasonville field was never brighter than at the present time. It is stated that the Lattas Creek, Island Valley and Bogle mines, three of the largest in the field, have closed contracts for sufficient orders to

keep the mines running at full time for at least four months.

An important sale of mining property in Greene county was closed by the transfer of 560 acres in Stafford township to a Chicago syndicate. The land is underlaid with a $4\frac{1}{2}$ -ft. vein of the best coal that has been discovered in the Linton district for several years.

The coke ovens at Black creek mine in Greene county will soon be placed in operation. Fires have been kindled in the ovens, and it is asserted that a big contract for coke for Gary is promised if the product proves satisfactory.

Victoria, B.C.

Feb. 16.—A bill was recently introduced into the provincial legislature of British Columbia with the object of protecting miners and other wage earners against a class of men, chiefly foreigners, who obtain options or working bonds on mining properties, employ men to do work, and then fail to pay them. The bill required such an operator to obtain from a responsible banker a certificate that he had on deposit in the bank sufficient money to pay two months' wages to the men he employed. While the government admitted that in some cases men were defrauded of their wages by irresponsible operators, in the way indicated by the supporters of the bill, it was not deemed advisable to pass the legislation asked for, since it could be carried to extremes, for it should not be applied to miners only, but to all classes of labor. Other serious objections were also raised to the measure, which was voted down by a vote of 22 to 13.

An attempt made by a socialist member of the provincial legislature of British Columbia to secure the enactment of a measure providing for the extension of the provincial eight-hour law, which limits the work of miners underground to eight hours per day, so as to apply to men working in open-pit mines, has been defeated. The premier, who is also minister of mines, argued, first, that there does not exist a general demand throughout the province for the enactment of the proposed amendment to the existing law, and, second, that it is not necessary for the physical protection, as had been claimed it is, of any large number of men. The socialists, the premier added, would like to have the eight-hour law made applicable to all phases of industry, which would greatly retard industry in the province. Particularly with the mining industry, as proposed in this instance, would it prove a drawback, and that industry, owing among other things to the considerable fall in the price of copper, needed encouragement rather than more restrictive legislation. Under the circumstances, therefore, it was necessary for the provincial government to move slowly

in making changes. The bill was rejected by a vote of 23 to 14.

London

Feb. 13.—During the six months ending Dec. 31, 1908, the report of the Dolcoath mine, Cornwall, shows that there were raised and milled 49,860 tons of tin ore, producing 902 tons of black tin or 49.52 lb. per long ton. The average price of black tin during this period was £77 17s. 2d., and the amount realized £70,238. The average receipts per ton of ore were 28s. 11d., and the total working costs 24s. 8d. per ton. The lords' royalties amounted to 1s. 11d. per ton, so that the company's net profit amounted only to 2s. 4d. per ton, or a total of £5891.

Some good ore is being met with at the bottom of the mine, a depth of 2940 ft.

The new vertical shaft being sunk to cut the lode at the 490-fathom level was down 2274 ft. at the close of the year, when there were still 666 ft. to sink. During the last six months the rate of sinking has been only 42 ft. per month, owing to trouble with water. Progress had been previously at the rate of 60 ft. per month. The cost of sinking during the last six months has averaged £30 per foot. The scheme of equipment for the new shaft has not yet been finally decided on, but it is understood that the pumping and hoisting plant will be electrically driven. To meet the capital expenditure required to complete the shaft the company has over £50,000 in cash or investments. The company's issued capital is £340,000 in £1 shares, which are valued today in the market at about 15s. Deducting the cash reserve, the mine may be said to be valued at £200,000.

If this is a fair value for the most famous mine in Cornwall, which is making some profits, and which promises to do much better in the future on account of the facilities for cheaper working that the new vertical shaft will afford, one wonders how it is that people can be found to buy shares in undeveloped mines in the same locality capitalized at double the amount. Yet at the present time business is being done, at prices that make the property far more valuable than Dolcoath, in the shares of a company that has acquired some of the old tin mines in the St. Ives district. The foundation of the boom in these particular mines is the occurrence of pitchblende, the radium contents of which are in some vague way to bring immense riches to the shareholders. How much pitchblende there is and what its commercial value is are questions that those who are buying the shares at high prices do not apparently stop to inquire. They must not, therefore, be surprised to find some years hence that mining for radium is not so profitable a business as the company promoter would have them believe.

Paris, France

Feb. 5.—The government of the Régency of Tunis is going to receive bids for the last portions of the line of the Nefzas. This line—length 75 km.—will secure an outlet on the Bizerta harbor for the rich iron mines of Kroumirie. The concessions, covering 5437 hectares, belong to the Compagnie des Mines de Fer de la Kroumirie et des Nefzas, which was promoted in 1906 by the Compagnie de Mokta-el-Hadid and the Compagnie des Mines de Fer des Nefzas. The mines were discovered early in the French occupation, but the presence of arsenic, though in small quantity (0.07 per cent. on an average) for a long time prevented their opening. They are mostly workable by open pit, rich, generally above 55 per cent. iron, and free from sulphur. They consist of very irregularly shaped lenses of partly hydrated silicious hematites, having generally an interstratified appearance, under the upper Eocene sandstone and over marl deposits of the same age. These ores will secure a return freight for the steamers that supply the important military harbor of Bizerta with coal. The absence of sulphur and phosphorus makes them compare favorably with the Bilbao ores.

The Nefzas line will also serve important concessions of zinc and lead, especially the Djebel-el-Grefa, belonging to the Compagnie Royale Asturienne des Mines. The ore appears as clayey lead carbonate of an almost constant average of 10 to 12 per cent., cementing together beds of conglomerates resting on Trias and of a thickness ranging between 100 and 200 m. The concentrating plant now erected has a capacity of 200 to 220 metric tons of ore per 24 hours.

A company is being formed to work alluvial gravels and auriferous laterite in Vakinankaratra province, in Madagascar. This company proposes to use Turner gold-saving tables in place of the old-fashioned batea, or pan.

It is also reported from Madagascar that an English engineer, Mr. Burls, has just discovered bituminous deposits in the Mlevatanana region, at 200 km. from the coast, which may be evidence of the presence of oil deeper down.

The Compagnie des Chemins de Fer du Congo Supérieur aux Grands Lacs Africains has discovered a chalcoprite bed of high tenor at 7 km. from Pontierville station. The last steamers from the Congo brought over specimens of ore, the average yield of which is said to be 30 per cent. copper. The company has started prospecting to determine the importance of this bed.

The French Chambers are about to discuss the matter of the Ouenza iron mines, Algeria, belonging to a syndicate in which some important French, English and German firms are concerned.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

Alabama

ETOWAH COUNTY

Quinn furnace at Gadsden is to be sold at public sale April 17. It has not been in blast for some time.

FRANKLIN COUNTY

Eureka Mining and Development Company—This company has sold its brown ore mines near Russellville to a syndicate represented by Henry B. McCormack, of Pennsylvania, for \$180,000. The property consists of 420 acres of ore lands and two mines which can ship 500 tons daily.

JEFFERSON COUNTY

Woodward Iron Company—Contracts have been let for grading and stripping at No. 2 iron mine at Red Mountain. A large tippie and crushers will be put up and the shipping capacity increased to 1000 tons of ore daily; at present it is 500 tons.

California

AMADOR COUNTY

Central Eureka—The main shaft is now 2120 ft. deep. The bottom of the old caved shaft will be reached in about four months.

South Eureka—Twenty stamps of the Central Eureka Mining Company's mill are working ore from this mine. The ore is conveyed from mine to mill by electric overhead tramway.

BUTTE COUNTY

Francisco—A stamp mill will soon be installed at this property at Enterprise where a rich vein was found some months ago.

DEL NORTE COUNTY

Oro Del Norte—This company, Dr. T. R. Heintz manager, has purchased the Dowdle property on the ocean beach near Crescent City, and an electric plant for saving the gold from the black sands of the ocean beach will be installed.

EL DORADO COUNTY

Sherman—Handsome specimen rock is being taken from this mine, near Placerville. Thos. Clark is superintendent.

Union—M. L. Effinger, resident manager of the San Francisco company which recently took charge of this mine at El

Dorado has kept 10 stamps running during January and will soon start up the other 10. This is a very old mine which has only been worked intermittently of late years.

HUMBOLDT COUNTY

David Minor has found a bed of talc 2 ft. thick at Glendale in the northern end of the county.

INYO COUNTY

Custer District—A new railroad is being built within 15 miles of this new mining camp, which is in the Argus range northwest of Death Valley and east of the Mohave desert. A great number of locations have been made and numerous prospectors have gone into the district in the past two months.

MONO COUNTY

Casa Diablo—The drifts which have followed the Dawn of Hope and Dry Bone veins have come together at about 300 ft. in from the tunnel. The ledge shows about 20 in. of good ore.

NEVADA COUNTY

Banner Ridge Drift—This company has been formed at Grass Valley with S. H. Dille as president and J. M. Wiley as secretary, to develop claims on the Wallace Macdonald ranch on Banner Ridge. There is already a hoisting and pumping outfit in place and an incline is being run to tap the gravel channel.

Brunswick—This company, with J. W. Pew as president, will sink a new vertical shaft to the east of the old one. The mine was formerly a producer; C. H. Malen is now superintendent.

Last Chance—This mine near Maybirt has been bonded by J. M. Fly, of the Marcotte company.

Oustomah—Operations have been partially suspended and the mill has been closed. Certain development work, however, is to be continued. The mine has reverted to its owners, the bondees having quit.

PLACER COUNTY

Southern Cross—The dam went out about two weeks since and it was impossible to run the mill, while the dam could not be repaired until spring. Therefore a gasoline engine was purchased and hauled with great difficulty over the narrow mountain trail through the snow from Gorge.

PLUMAS COUNTY

Star Spangled Banner—This group, including the Flagstaff and Pennant claims, on Rush creek not far from Greenville, is about to be thoroughly prospected.

SHASTA COUNTY

Hazel—The company, operating the Gladstone mine at French Gulch, has purchased an electric locomotive for use in its 4000-ft. tunnel.

SISKIYOU COUNTY

Gardner & Weed—Water has been turned into the ditches at Fort Jones and a full crew is now handling the three giants.

Granite & Crosscut—At the Granite mine on Humbug creek, Chas. A. Mitchell manager, very good ore has lately been taken out. The mill has been overhauled and put in order.

TRINITY COUNTY

Trinity Gold and Timber Company—This company, W. V. Whipple manager, operating the Beaudry mines at Minersville, has installed three giants and has an abundant water supply. The company is making arrangements to install a dredge on the low benches of the property.

TUOLUMNE COUNTY

McCormick—The property near Jacksonville, Edward Butt superintendent, has a new pipe line, and high-grade ore is being taken out.

Springfield Tunnel—This mine, near Columbia, has had considerable trouble with water and heavier machinery has been installed, including a new air compressor.

Gold Ship—At Groveland, Wm. Graham superintendent, arrangements for working on a large scale are being made. It is owned principally by Kansas City and Boston men.

Colorado

LAKE COUNTY—LEADVILLE

Alice Placer—A new shaft is being sunk on this ground, Carbonate hill, by lessees and when sufficient depth is gained, drifting toward the Penrose will be started. A large body of iron ore exists on the Penrose line.

Baby Shaft—A large body of low-grade iron ore has been opened in this property.

Iron hill, but as work proceeds on it the value increases.

Cleveland Shaft—This shaft, South Evans gulch, is now down 760 ft., leaving 65 ft. to be sunk to complete the present contract of 200 ft. The shaft is being sunk in porphyry and but little trouble is encountered from water.

Coronado—The lessees on this property, Down-town section, have opened up a large body of argentiferous iron, and during the week put on a double shift of men. Shipments at the rate of 30 tons daily are being sent to the smelter.

Ibex—Connections have been made between shaft No. 3 and No. 4 from the lower level of the latter shaft. This permits the ground between the two shafts to be thoroughly drained, and will also allow development work to be carried on at greater depth in No. 3 shaft.

Lilian—The lessees on this property, Iowa gulch, are shipping ore that will run high in gold. The work is being carried on at the lower levels.

Yak Tunnel—Ten drill holes have tapped the water in the Resurrection and it is being lowered at the rate of 12 ft. per day. The tunnel is now being driven ahead into Big Evans basin.

SAN JUAN COUNTY

Ross Mining and Milling Company—This company is now operating the old Congress mine at Red Mountain. Development work has been begun on the 270-ft. level of the old shaft. J. B. Ross is manager and Patrick Loneragan, superintendent.

Florida

Prairie Pebble Phosphate Company—The Holmboe Company, Louisville, Ky., has taken the contract to build extensive additions to this company's plant at Mulberry.

Georgia

LUMPKIN COUNTY

Liberty Bell Gold Mining Company—A new ditch, 22 miles long, is being built to carry water to this company's mine near Auraria.

Indiana

SULLIVAN COUNTY

Following the suit for a receiver for the Hudson Coal and Mining Company, other suits on account are being filed. The debt was supposed to be about \$3000, but the amount has grown to nearly \$50,000, and other claims and assets are to follow.

Fire broke out again in the Shirley Hill Company's Clover Leaf mine, in the east part of the county. The fire is the fifth in a few months in that mine. The coal contains an unusual quantity of gas.

WARRICK COUNTY

Patrick Bartley, boss of the Menden coal mine, near Boonville, has been arraigned before Justice Youngblood on three charges prepared by the State mine inspector. The charge of acting as his own fireboss was sustained and a fine imposed. The charge of not having his mine inspected on Aug. 10 was continued for a future hearing.

Michigan

COPPER

Winona—This company has levied an assessment of \$1 per share payable March 9. This is to furnish additional funds for development work and the erection of a stamp mill, which will be owned jointly by this and the King Phillips company, now under the same management. This will be a four-head mill located on the banks of the Sleepy river and near the working shafts of the two companies. The lower levels of both companies are encountering good ground and the Winona has sufficient ground blocked out to ship about 800 tons daily to the mill, for a number of years.

Isle Royal—The shaft that this company is sinking to open up the Baltic lode is down about 110 ft. At No. 6 shaft the new boiler house and the air compressor have gone into service and will soon be followed by the new high-duty hoisting engine.

Lake—Sinking continues below a depth of 460 ft. in good, copper ground. Preparations for the third level have been made at a depth of 415 ft. Drifting continues on the two upper levels.

North Lake—Diamond drilling continues at this property making two parallel cross-sections of the tract.

Seneca—This company has driven the crosscut from the first level, a distance of 250 ft. from surface, a distance of 75 ft., and the formation indicates close proximity to the formation. Diamond-drill cores taken from the site showed mineralization.

Ahmeek—The erection of the structural steel for the new stamp mill is to be rushed so that the building will be ready in the early spring. At the mine alterations are being made at the central crushing plant to take care of the increased production that will be made when its mill is ready to go into commission. Sinking has been resumed at No. 3 shaft after completing the concrete collar which extends through the overburden a distance of about 70 feet.

Missouri

WAYNE COUNTY

Wayne Iron and Lumber Company—Development work has been begun on a large deposit of iron ore near Green-

ville. W. N. Mitchell, of Chicago, is president.

ZINC-LEAD DISTRICT

Kenmore—This company has been incorporated with a capital stock of \$100,000 to operate near Carl Junction. H. D. Hanway, manager, D. V. Sholl and other Joplin parties are the stockholders.

Little Princess—This company has sold the largest pile of reserve ore in the district. The sale amounted to 1,991,920 lb. of jack.

Little Maxine—A contract for a 200-ton mill on this lease near the Emma Gordon, has been let. J. L. Call is manager.

Maltes Brothers—The new 500-ton mill west of Joplin has started grinding ore.

Sarcxie—This camp is taking on the appearance of a boom; 21 shafts have been sunk since the middle of December. The Optimo company has let six subleases on its ground.

Montana

BUTTE DISTRICT

Amalgamated—At the St. Lawrence, Never Sweat and Anaconda mines operations are still considerably retarded by gases from the mine fires. On the 1600 level of the Anaconda a connection has been made with the Belmont shaft. The Belmont is being sunk for the purpose of enabling the working of the Anaconda group at a point below the fire zone, the plan being similar to that being put in execution at the Tramway shaft of the Red Metal Company, where the Minnie Healy mine is being worked at a depth below the fire zone. Although there has been no recent reduction in the force employed in the Amalgamated properties, the number is only about two-thirds as great as that of two years ago. Production in comparison to the number of men working is greater than ever before.

Butte-Montana—The mine was shut down the latter part of last week for the purpose of installing new machinery, the present plant being no longer able to do the work at the depth reached.

Reins—It is reported that this property is shortly to be opened up.

JEFFERSON COUNTY

Corbin Consolidated Mining Company—The entire outstanding stock of the company is under option to J. L. Meixell, of Butte. This property directly adjoins that of the Boston Corbin Company and comprises four claims.

Nevada

ESMERALDA COUNTY—GOLDFIELD

St. Ives Lease—This lease, managed by A. A. Codd and located on the St. Ives claim of the Goldfield Merger Company's ground, shipped 15 tons last week to the

Nevada Goldfield Reduction Company; the ore averaged about \$60 per ton.

Great Bend Diadem—Recent developments in connection with the strike reported on this property last week have proved it to be one of very great importance, since examination has shown the orebody to be associated with dacite. This fact has great bearing on the question of permanency, as in no instance in Goldfield, excepting the Sandstorm, have permanent orebodies been found unassociated with the dacite. A shipment is now being prepared.

Goldfield Daisy—Sinking is to be resumed in the No. 2 or Truett shaft, and carried on from the 400-ft. to the 700-ft. level. At present most of the ore shipped is taken from the old shoot on the 200-ft. level, and a lesser amount from the 300-ft. level. The crosscut on the 400-ft. level is being pushed to get under the ore-shoot.

ESMERALDA COUNTY—PALMETTO

Palmetto Death Valley Mining Company—Work has been resumed on this ground by men holding an 18-months' lease on the mine and mill. Ore is being taken out and hauled to the mill, five miles distant. The ore is of milling grade averaging about \$18 per ton.

ESMERALDA COUNTY—GOLD MOUNTAIN

Nevada Empress—It is reported that the mill will be placed in commission by March 15. In a well recently sunk, sufficient water has been developed to supply a 30-ton mill; a pipe line connecting the well and mill has been laid, and an engine and pump installed. A new vein, 3 ft. wide, was recently cut; samples from it assay \$20 per ton. Fifteen men are now employed on the property.

ESMERALDA COUNTY—HORNSILVER

Great Western—The outlook for this property is favorable, as ore is being shipped from both levels. Development work is also being carried on. On the 200-ft. level ore is mined in both the east and the west drifts, the ore assaying well in gold and silver. On the 300-ft. level in a raise east of the shaft, a streak, 18 in. wide has been opened which also assays well in gold and silver. The ore is at present shipped to the Belmont mill at Millers.

Cottrell Group—A strike is reported on this property which lies immediately east of the Great Western. The property has been worked intermittently for some months. Ore was first found at a depth of 15 ft. in a shaft sunk to intercept a blind lode. The vein was lost, and a new shaft was sunk to prospect for it. In this new shaft at a depth of 55 ft. the vein was picked up and had been drifted upon for a distance of 35 ft. The vein is 4 ft. wide and contains much shipping ore.

About ten tons of this gold and silver ore are now ready for shipment.

ESMERALDA COUNTY—RAWHIDE

Rawhide Queen—The company has found the orebody in the Kerns No. 2 lease which was abandoned some time ago by the leasers after considerable prospecting for the oreshoot. This shoot of ore is rich and contains considerable visible gold, some large specimens of native gold having been found in the vein. The Kerns No. 1 lease continues to ship a good grade of ore. The Domic lease also continues to ship a good grade of ore. The shaft at this lease is to be sunk deeper. At the St. Ives lease, also on the Queen property, a drift is being driven to catch the oreshoot worked in the Kerns No. 2 lease. Lately a body of rich ore was struck in this lease.

Murray Lease—The mill is running regularly on the ore from the lease. Recently a streak of rich ore was found on the 200-ft. level of this lease.

Marigold Lease—A good body of rich ore was found on the 130-ft. level last week. The Marigold lease and the Grutt Hill-Truitt leases are worked through the same shaft.

Grutt Hill Mint—Rich ore has been found on the 320-ft. level of this lease on the Coalition property. The orebody has been crosscutted for 6 ft. without reaching the footwall. This company has acquired the Grutt Hill Coalition lease which adjoins the Mint lease. The two leases will henceforth be worked through the Coalition shaft, which is vertical, instead of through the Mint shaft which is an incline.

NYE COUNTY—TONOPAH

Jim Butler—This property shipped 250 tons of ore during the week ending Feb. 13. This ore came from the 100-ft. and the 200-ft. levels. No development work is carried on at present.

MacNamara—At a meeting held Feb. 6 a dividend of 1c. per share was declared payable March 5, the books of the company closing for transfer Feb. 20. Sinking was resumed Feb. 10 in the main shaft, now 500 ft. deep. This shaft is to be sunk to a depth of 800 ft., at which point a drift will be started to find the body of quartz cut by the drill at a depth of 785 feet.

Tonopah Mining Company—At the Mizpah shaft the water column was placed in position last week from the 1200-ft. level to the surface. The station has been completed, and work has commenced on the foundation for the pump. The usual amount of development work was carried on in all the levels, 360 ft. of new ground being broken. At the Silver Top shaft, the drill hole from the 740-ft. level is now 435 ft. below that level; 126 ft. of new ground was broken during the week. At the Red Plume shaft, sinking was resumed on Feb. 10; this shaft, now 500 ft.

deep, will be sunk to a depth of 700 ft. On the 600-ft. level, prospecting for the quartz cut by the drill at that depth will be done. At the mill 3170 tons of ore, valued at \$21.50 per ton, were crushed during the week; 64 bars of bullion worth \$53,760 and 52,000 lb. of concentrates valued at \$12,300 were shipped.

Tonopah Belmont—In a raise from the west drift on the south vein on the 1000-ft. level, 4 ft. of good milling ore was opened last week, and in a raise from the west drift following the Mizpah fault on the 1000-ft. level another orebody 4 ft. wide and containing good milling ore has been found. The stope from the 1100-ft. level shows a big orebody of good milling grade, more than 10 ft. wide.

NYE COUNTY—ROUND MOUNTAIN

Round Mountain Mining Company—The clean-up for the month of January, during which month 2770 tons of ore was treated, amounted to \$33,600. The company will increase the capacity of the mill to 110 tons; it is negotiating with the Nevada Electric Power Company for an extension of its lines from Millers to Round Mountain.

HUMBOLDT COUNTY—SEVEN TROUGHS

Harris Lease—In sinking a winze from the 200-ft. level an oxidized vein was cut which shows a good milling ore for a width of 10 ft. In drifting on an east and west vein that was cut in a crosscut on the bottom level of the property, a round of shots disclosed the entire breast to be of high-grade shipping ore.

Wihuja Lease—This property is preparing a shipment to the Kindergarten mill. This ore comes from the 375-ft. level and is the best ore ever taken from the mine.

Mazuma Hills—At the Prior-Chadbourne lease, a rich strike is reported on the 250-ft. level where 15 in. of rich ore has been opened. Three inches of this is very rich tale, and the remaining 12 in. black quartz of shipping grade. The oreshoot is on the Reagan vein from which one carload sent to the smelter averaged \$1030 per ton.

Pennsylvania

BITUMINOUS COAL.

Pittsburg-Westmoreland Coal Company—This company is offering \$500,000 in 5 per cent. first-mortgage bonds, part of an authorized total of \$6,000,000, of which \$3,325,000 are outstanding. The company owns 16,500 acres of coal lands, and has eight large mines in operation, with two others being opened.

Texas

LLANO COUNTY

The rich deposits of iron ore in this county are being examined by Dr. William B. Phillips, of Birmingham, Ala. The

property will be prospected by diamond-core drilling, test pits and shafts. Steam drills will be used and a thorough examination made; the work will probably take several months. The ores are magnetites and hematites, in granite and gneiss, and are known to be rich, carrying 60 to 65 per cent. iron, and not over 0.05 phosphorus. The property belongs to R. H. Downman, of New Orleans, and the Wakefield Iron Company, of Minneapolis. It is about 15 miles northwest of the town of Llano, which is 100 miles northwest of Austin. The chief object of this examination is to determine the commercial value of the deposits.

South Dakota

LAWRENCE COUNTY

Burlington—It is reported that development work is to be resumed upon the property. The shaft is down 180 ft., and will be sunk 250 ft. before drifting is commenced. The vein followed dips almost vertically.

Rainbow—At the annual stockholders' meeting, held at Deadwood Feb. 15, the following directors were elected: John Baker, W. H. Bonham, Clara D. Coe, E. M. Dale, J. H. Gerard, W. A. Ickes, E. P. Peterson. E. P. Peterson was elected president; E. M. Dale, vice-president, and Clara D. Coe, secretary and treasurer.

Utah

JOAB COUNTY

East Crown Point—The shaft, now 140 ft. deep, will be sunk to a depth of 300 feet.

Tintic Development Company—High-grade lead ore has been struck in the face of the north drift at a depth of 230 ft. Hoisting equipment and a four-drill compressor have been ordered.

SALT LAKE COUNTY

Boston Consolidated—The annual report of the company shows expenditures during last year of \$832,266 upon construction and development, of which \$651,883 was expended upon the Garfield mill and \$70,766 in steam-shovel stripping of overburden. A total of \$937,658 was received from the sale of metal, which was all put back in the property for operating and construction. At the Garfield mill recoveries range from 70 to 72 per cent., and milling costs were reduced from \$1 to 47.2c. per ton. About 2000 tons of ore are treated daily.

Philippine Islands

BENGUET

Benguet Consolidated—This company reports for the month of November a production of 209 oz. gold and 310 lb. cyanide bullion.

Headwaters Mining Company—The prospect adits on this company's property are showing good ore, carrying free gold. On the northern lead the adit showed good returns, but to avoid trouble from floods it has been closed, and another started higher up the hill, where the entrance and dumps will be safe from flood waters.

CAMARINES

Another dredge has arrived at Paracale and as soon as the pontoons are erected and the machinery installed active operations will begin on the headwaters of the Paracale river. J. H. Jones is in charge of the installation. This dredge is the property of New Zealand men.

Paracale Gold Dredging Company—This company, operating on the Paracale river, reports a saving of 626 oz. gold in November.

Tumbaga—This old mine has been pumped out and prepared for the installation of machinery. Samples taken out have proved satisfactory, and much of the old machinery is in good condition. This will be reinforced by additions to the equipment and it is expected that the mine will be in operation and milling started in February or March.

Canada

BRITISH COLUMBIA

A statement of the revenue and expenditure of the province for six months ended Dec. 31, 1908, recently submitted to the local legislature, reports that the revenue from the mining industry during that period was as follows: From free miners' certificates, \$11,067; general mining receipts, \$58,890; mineral tax, \$58,134; tax on unworked Crown-granted mineral claims, \$21,362; royalty and tax on coal, \$82,950; sundry receipts not specified, estimated at \$17,000; total, \$250,403 for the half-year.

BRITISH COLUMBIA—TRAIL

During 1908 there was smelted at the works of the Consolidated Mining and Smelting Company of Canada, Ltd., at Trail, ore as follows: In lead furnaces, ore and concentrates, 51,022 tons; in copper furnaces, 267,384 tons; total, 318,406 tons. The metal production was:

	Quantity.	Gross Value.
Gold, oz.	116,314	\$2,383,327
Silver, oz.	2,100,457	1,102,843
Copper, lb.	3,753,139	506,460
Lead, lb.	35,999,145	1,050,455
Total value.		\$5,043,085

Included in the output was the production of the company's St. Eugene lead-silver mine at Moyie, Centre Star group of gold-copper mines at Rossland, Snowshoe mine (leased) at Phenix, Boundary district, and custom ores and concentrates purchased.

BRITISH COLUMBIA—VANCOUVER ISLAND

The total output of coal in 1908 in the Coast district was 1,229,328 long tons. The greater part of this production was from the mines of the Wellington Colliery Company, at Cumberland and Extension, and of the Western Fuel Company near Nanaimo, all on Vancouver island.

The corporate name of the company heretofore known as the Britannia Smelting Company, Ltd., is to be changed to the Britannia Mining and Smelting Company, Ltd. The new company, the stock in which is largely held in New York, will be an amalgamation of the Britannia Smelting Company and the Britannia Copper Syndicate. The latter owned, and has been operating for several years, the Britannia group of copper mines, near Vancouver, and the former the smelting works at Crofton, Vancouver Island. T. Mason Adams will continue as general manager.

BRITISH COLUMBIA—BOUNDARY

At Vancouver, in the Supreme Court of British Columbia, Mr. Justice Clement has adjourned the case of the National Trust Company, of Toronto, Ont., acting as trustee for the bondholders, against the Dominion Copper Company, so as to give counsel opportunity to agree as to which of the assets of the defendant company are exempted from the plaintiff's security in connection with the bond issue made in June, 1905. Plaintiff asks for a foreclosure order to include all the assets, but defendant claims that certain of the assets are not included in the plaintiff's security.

BRITISH COLUMBIA—NELSON

J. McMartin, well known at Cobalt, where he is interested in the La Rose and other mining properties, has arranged to acquire the Kootenay Belle and Mother Lode groups of mineral claims, in Sheep Creek camp, Nelson division. From half a dozen properties in this camp nearly \$700,000 in gold has been produced, of which more than \$100,000 was from the Kootenay Belle and Mother Lode. Hitherto development of these two mines has been on only a small scale. On the Kootenay Belle tungsten, occurring here in association with the gold ore, is stated to be in the purest form yet found in Canada.

BRITISH COLUMBIA—TRAIL

A return made by the secretary of State for Canada shows that, beside gold and bronze coins made at the Canadian branch of the Royal Mint, Ottawa, Ontario, at which coinage was commenced last year, there has been coined \$313,338 in silver, purchased from the Consolidated Mining and Smelting Company, of Canada, Ltd. This company supplied the mint with 387,850 oz. of fine silver, which was smelted and refined at its works at Trail.

BRITISH COLUMBIA—SLOCAN

Another stage has been reached in the Star Mining and Milling Company vs. Byron N. White Company litigation, the Supreme Court of Canada having dismissed the appeal of the defendant company against the judgment of the Full Court of British Columbia, which was in favor of the plaintiff company. This case has been before the courts for years. It involves questions of extra lateral rights.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ending Feb. 13 were as follows: City of Cobalt, 61,000 lb.; Crown Reserve, 41,970; La Rose, 194,140; McKinley-Darragh, 40,000; Nipissing, 128,957; Silver Queen, 65,000; Trethewey, 92,530; total, 623,597 pounds.

Cobalt-Majestic—This company, formerly the Abitibi & Columbia, has been ordered by the Provincial secretary again to change its name on account of the confusion arising between it and the Kerr Lake-Majestic.

Right of Way—At the annual meeting held at Ottawa Feb. 17, a dividend of 6 per cent. with a 9-per cent. bonus was declared for the quarter ending March 31. It was announced that the company would be placed on a 6-per cent. quarterly basis with whatever bonus in addition might be advisable. The value of the output for the year was \$215,000.

Silver Queen—The directors have decided to pass the usual dividend of 3 per cent. per quarter. President F. L. Culver stated that the company had plenty of money on hand, but having run into a lean streak of ore, the directors considered it advisable to retain it in order to keep up development work until good paying ore was again reached.

ONTARIO—GOWGANDA

Bartlett—About 20 men are at work completing the construction of large camp buildings. Active mining work will begin in about two weeks.

YUKON TERRITORY—WHITEHORSE

The local board of trade has resolved to ask the Yukon territorial authorities for an appropriation of \$5000 for the cable ferry over the Donjek river and for improving the road from Whitehorse by Klauane to the White river country, in which numerous copper claims have been located on both sides of the International boundary line. It is claimed that those in charge of International boundary survey parties support the Whitehorse-Klauane route as the best.

Frederick T. Congdon, recently elected member of the Dominion House of Commons for Yukon Territory, has announced his intention to endeavor to secure an

adequate appropriation for more roads in the Yukon, especially along the White, Stewart and McMillan rivers, on which important mining enterprises have been undertaken.

Mexico

CHIHUAHUA

Bullion Shipments—Recent bullion shipments passing through the banks of Chihuahua include the following: Batopilas, 205 bars silver valued at 216,000 pesos; Watterson, 11 bars gold-silver of value of 26,000 pesos; Benito Martinez and Martinez & La Rive, each 2 bars silver valued at 2000 pesos each.

Naica—As the result of recent ore discoveries more interest is now evinced in this district and a number of the newer companies have increased the extent of development operations, among these being the Compañía des Mines de Chihuahua and Naica Mining Company. A recent directors' report shows that the Naica company shipped during 1908, 16,820 tons of ore and that there is still available for immediate extraction upward of 140,000 tons.

SONORA

Candelero—The mines, at La Barranca, have been acquired by this company of Oklahoma City and are opening up five different veins of gold-silver ore. A tunnel is being driven into Candelero mountain to cut the Candelero vein, the mother vein of the section. This tunnel is now in 500 ft. with 300 ft. to go. A compressor plant, concentrating tables, and a cyanide plant will be installed soon. S. Been Smith is superintendent.

Creston Colorado—The Colorado mill is treating 5000 tons of Colorado ores per month, which are running from \$8 to \$20 per ton. The old Grand Central mill, leased by this company, is regrinding by tube mill and is cyaniding in the old original Butters plant about 8000 tons per month of the old tailings of the Colorado mill. These tailings are from both Colorado and Creston ores. The Creston mine is closed down. These mines are at Minas Prietas, about 20 miles cast from Torres on the Sonora railroad.

La Dura—The Cananea Rio Yaqui y Pacifico railroad has its construction camps as far up the Yaqui river as La Dura and in the five camps between there and the present end of the road has 1500 men at work on construction. The track-laying machine is expected to reach La Dura about April 1.

Las Góteras—The mine, one-half mile from La Barranca, is preparing to install mining and milling machinery. A telephone line is being constructed to connect San Javier, Las Góteras, Candelero, and Toledo, with La Dura. Fred Foreshaw is mine superintendent.

Minneapolis Copper Company—This company at San Antonio de la Huerta is running its mill on free milling ore recently opened up by the new management.

Sonora Mining and Development Company—The Las Animas mine of this company, in the San Javier district, is being pumped out. When this is accomplished experiments will be made on the ores in the bottom of the mine to determine the process of treatment best adapted and a plant will be constructed. Frank Davis, of Alamos, is the general manager.

Southern Republic Mining Company—The Southern Republic, operating west of Noria on the Sonora railroad, is prospecting for copper with churn drills.

Yaqui Smelting and Refining Company—It is reported that the company's silver-lead smelter at Toledo is to resume operations. Frank Davis, of Alamos built the plant but was obliged to close down on account of Yaqui Indian outrages.

Greene Gold-Silver Company—On Feb. 12 the concession to W. C. Greene, covering nearly 3,000,000 acres of mineral-bearing ground in Chihuahua and Sonora, expired by limitation. There was immediately a rush by prospectors and miners to secure many valuable locations on the then open territory, but to the disappointment of the denouncers the local officials refused to file the claims. The reason of this refusal has turned out to be that special orders were sent to the Chihuahua officials not to accept denouncements on that territory until further notice, on account of an investigation pending to determine whether or not Colonel Greene has fulfilled the terms of his concession.

Lista Blanca Copper—This company has been incorporated at Nogales under the laws of Arizona to hold the total capital stock of the Compañía Minera de Cobre Lista Blanca, S. A., the Mexico corporation owning the Lista Blanca property in the Altar district about nine miles west from Caborca. The property has a great deal of development work and considerable ore blocked out and it is the intention of the new company to install a modern reduction plant. Henry Levin is resident agent.

Noria—This new town on the Sonora railroad is the distributing center for the Sonora Copper Company, La Cobriza Mining Company, and the Llano Copper Company. The first two are said to be contemplating the early erection of smelters.

Tribune—In the Rey de Oro mine beyond Cerro Prieto in the Magdalena district a shoot of high-grade gold ore has been encountered in the midst of the large deposits of low-grade ore being worked. A winze on the new strike is down 20 ft. The mill, which has been shut down for some time owing to a breakdown, will be ready to drop stamps again in about two weeks.

Metal, Mineral, Coal and Stock Markets

Current Prices, Market Conditions and Commercial Statistics of the Metals, Minerals and Mining Stocks

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, Feb. 24—The coal trade in the East continues on about the same level as by our last report. No special activity has developed, although in some sections there is rather steadier demand for coal, but not enough to affect the market to any considerable degree. In the interior bituminous-coal trade a somewhat greater demand for steam coal is beginning to develop, although progress is slow.

In the anthracite trade the main topic of discussion is the probability of a strike in April. While no public announcement has been made, it is generally accepted as certain that the anthracite-coal companies will not open discussion of the disputed questions with the representatives of the Miners' union, thereby rejecting at the outset the principal demand of the union. The other points raised about wages and minor details could probably be adjusted without much difficulty, but the companies seem determined to insist upon the open-shop principle. They are also opposed to the abolition of the conciliation board and to the limit of the agreement to one year. It is quite probable that they have accepted the present as a good time to try conclusions with the union. They have accumulated stocks of the domestic sizes of coal sufficient to carry them for some time, although the small steam sizes would probably run short very quickly.

In the West the coal trade is quiet, with a moderate increase in domestic trade owing to the prevalence of colder weather. The steam-coal trade shows very little variation except that several large concerns have shown considerable interest in yearly contracts and some of encouraging amount have been closed.

The coke business is showing a decided improvement and shipments over the various railroads have increased considerably since the beginning of the year.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to Feb. 13, short tons:

	1908.	1909.	Changes.
Anthracite.....	658,927	598,696	D. 60,231
Bituminous.....	3,938,080	4,152,129	I. 213,449
Coke.....	876,939	1,205,309	I. 329,370
Total.....	5,473,946	6,956,134	I. 482,588

The total increase this year to date was 8.8 per cent.

New York

ANTHRACITE

Feb. 24—Business continues quiet with

no change in prices. The weather has not been cold enough to cause any increase in demand even in a retail way. Temporarily there is rather a scarcity of the small steam sizes. This is owing to the fact that operations at many of the larger collieries have been curtailed and in consequence less steam coal is made. Moreover, some consumers of the small sizes have been putting in stocks ahead in order to provide for a possible stoppage of mining, thus increasing the demand at a time when the supply was not over abundant.

Prices are unchanged. The list prices for prepared sizes are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points.

BITUMINOUS

The soft-coal market continues quiet, although the aggregate quantity of coal handled is large, as it always is even in dull times. Contracts are still being talked about, but very few have been closed. The prices offered—and in some cases accepted—are lower than last year, but in most cases better than the current market.

Trade in the far East is dead and no coal is being taken for that section. Along the Sound there is some buying and it may be noted that this is steadier than it was recently. New York harbor is still dull, though some coal is being taken and consumers are showing a little more interest.

Prices show no material change. In New York harbor good grades of steam coal are selling at \$2.40@2.50, f.o.b. harbor shipping port, while lower grades can be had at \$2.20@2.30 per ton.

All-rail trade is better than tidewater and the interior cities are taking a fair amount of coal. Car supply is abundant and transportation good, with very few delays.

The Coastwise market is dull and vessels are still looking for charters. There is no change in freight rates, those quoted for large vessels from Philadelphia being: Boston, Salem and Portland, 75c.; Lynn and Bath, 85c.; Portsmouth, Soc.; Newburyport, 95c.; Providence, New Bedford and the Sound, 65@70c. per ton.

Birmingham

Feb. 22—Further curtailment in production is noted in the coal-mining section of Alabama, several mines being closed down

now or running on half time and less. There is no demand for coal. The larger furnace companies have stacked up enough coke to warrant a cessation at several batteries of coke ovens. There is but little domestic demand for coal. Prices are beginning to descend, but this does not bring about any business. The mining concerns do not look for any immediate improvement in the general conditions.

Chicago

Feb. 22—The coal market continues fairly strong, for both steam and domestic coals. Not only is the demand somewhat better, but the market is lightened by lighter shipments. Weather conditions have not been such as to predicate continuance of the existing conditions, however, and the coming week, with mild temperatures over Chicago territory indicated, will probably see a slack demand. Buying is so responsive to changes in temperature, for domestic coals, that consumers and dealers appear generally to have small supplies. Steam coals are evidently being bought close to current needs, and there is no apparent increase in these needs. The industrial situation, however, is bettering slowly. Eastern coals have improved in tone in this market, and smokeless is notably improved owing to lessened shipments, though still in large supply and with prices on run-of-mine 15@25c. under circular prices.

Illinois and Indiana coals bring, in car lots, \$1.80@2.40 for lump, \$1.60@1.75 for run-of-mine and \$1.30@1.60 for slack. Smokeless sells at \$2.75@3.15 for Pocahontas and New River run-of-mine, and \$3.15@3.45 for lump or egg. Hocking is in much better condition, the demand being large and the supply not curtailed so as to remove demurrage sales, holding the price up close to \$3.15, circular quotation. Eastern gas coals have a light but steady demand with stationary prices. Anthracite continues to have a good run of sales for small lots, but well distributed.

Cleveland

Feb. 23—The demand for domestic coal resulting from the weather still gives some activity to the market, though it is gradually falling off. Steam coal is in moderate demand, the tendency still being to buy slack rather than run-of-mine or lump. There is not much demurrage coal in evidence here, to depress prices.

Discussion of Lake rates is in order, but very little has been done so far. Much depends on the demand for iron ore and the number of ore boats going back light and ready to take coal cargoes.

Pittsburg

Feb. 23—There has been no change in operations during the week, production in the Pittsburg district being at the rate of about 35 per cent. of capacity of the mines. Prices are being firmly held at \$1.15 a ton for mine-run coal at mine. Slack is quoted at 65c. The rivers were navigable the last few days of the week and fully 2,000,000 bu. coal went to lower ports, almost cleaning up the accumulated stocks in the pools and harbor. There are plenty of empty coal boats and barges here and all the river mines are in operation and will be kept going steadily.

Connellsville Coke—The coke trade continues dull and prices are weaker. Production has not been curtailed to a great extent. Large producers who had endeavored to maintain prices on foundry coke have made a reduction. Foundry coke for delivery in the second half is quoted at \$2@2.15 and for spot shipment \$2 is the lowest price named. Furnace coke is held at \$1.75 for spot and \$1.90 on contract but it is possible to shade these prices. The *Courier* gives the production of coke in both of the Connellsville fields at 268,958 tons. Shipments amounted to 9643 cars as follows: To Pittsburg district, 3490; to points west of Pittsburg, 5516; to points east of Connellsville, 637 cars.

Foreign Coal Trade

Nova Scotia Coal—Shipments of coal from Nova Scotia mines in January are reported as follows, in long tons:

	1908.	1909.	Changes.
Dominion	202,063	120,130	D. 81,933
Nova Scotia Steel ..	38,945	47,750	I. 8,805
Cumberland	27,015	27,294	I. 279
Acadia	29,433	24,852	D. 4,581
Inverness	24,948	19,767	D. 5,181
Intercolonial	322,304	239,793	D. 82,511

No report for the month received from the Inverness Coal Company. Total decrease this year, 25.6 per cent.

British Coal Exports—Coal exports from Great Britain, with coal sent abroad for use of steamers in foreign trade, for the month of January, long tons:

	1908.	1909.	Changes.
Coal	4,677,800	4,308,635	D. 369,165
Coke	108,506	75,761	D. 32,745
Brickbats	132,324	110,108	D. 22,216
Total exports ..	4,918,630	4,494,504	D. 424,126
Steamer coal	1,608,253	1,600,743	D. 7,510
Total	6,526,883	6,095,247	D. 531,636

The larger exports this year were 803,725 tons to France, 712,801 to Italy, and 468,902 to Germany. Exports to the United States were 1158 tons.

Belgian Coal Production—The production of coal in Belgium for the full year was 23,824,499 metric tons in 1907, and 23,678,150 in 1908; a decrease of 146,349 tons. Unsold stocks on Dec. 31, 1908, were 917,330 tons, an increase of 475,712 tons over the previous year.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff. report current prices of coal as follows, on Feb. 13; Best Welsh steam, \$3.36; seconds, \$3.24; thirds, \$3.12; dry coals, \$3.48; best Monmouthshire, \$3.06; seconds, \$2.94; best small steam, \$2.10; seconds, \$1.80. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, Feb. 24—The iron and steel trades have shown a marked contrast to the inactivity of recent weeks. In our last report we mention that a general meeting of the steel trade had been held in New York and stated that reductions in prices were almost certain to follow. The announcement did, in fact, come two days later, but instead of taking the form of a new schedule of prices put out by the leading interest, it was announced that Steel Corporation agents had received orders to meet the cuts made recently by independent manufacturers and if necessary to go below them. This left the market an open one, with the assurance that the leading interest would not hold back, but would make such concessions as might be necessary to secure business.

Under the new order sales are reported at prices which imply a cut of from \$6 to \$8 per ton in plates, \$4 in steel bars and at least \$7 in structural steel. Bars had previously been rather demoralized and both iron and steel bars are now selling at around 1.20c. at mill, with some sales reported at 1.15c. and even 1.10c. is talked about. As to the extent of these sales it is difficult to make an estimate. Many reports are current and the market has hardly had time enough to adjust itself to the new conditions. One important point is that a number of contracts for buildings which have been held back for some time are being rushed forward, to take advantage of the lower prices of material now possible. In another week, probably, the real effect of the reduction will be manifest. The general belief is that a large amount of business will be placed.

One important point is that under the new orders two basing points have been adopted, rates being made on the basis of Chicago delivery as well as at Pittsburg. Whether this is intended to be permanent or not has not been stated. Probably it will be so and will refer to delivery from the Gary works as well as Chicago.

Steel rails were not included in the order for reduction and it is understood that prices are a subject of conference

among the rail makers. It has been reported that one or two rail mills have made tentative offers to sell heavy sections at \$25, but this cannot be confirmed.

Upon the whole—while as we have said, it is still difficult to appreciate the full effect upon the market—the indications are that a considerable revival in business may be expected and that consumers will take more interest than they have done for some time past, when they appreciate that their views on prices are being met, and that considerable economies can be secured by purchasing material at the present time.

There has been some improvement in the demand for pig iron. Furnaces generally appear to be ready to make concessions except on special brands. Southern pig iron has been cut from \$13 to \$12.50 Birmingham for No. 2 foundry and some sales are reported at even lower prices. Other concessions will probably follow.

It is intimated in many quarters that reductions in prices will probably be followed by equal reductions in wages. This is altogether probable and many such reductions will be made, though not perhaps immediately. In fact, wages in some important branches of the trade are governed by agreements which still have some time to run and which cannot be changed at once.

Baltimore

Exports for the week included 195,110 lb. spelter, 112,000 lb. lead and 3,051,000 lb. steel billets to Great Britain; 4773 tons steel rails to Panama; 758 tons steel rails and 352 tons track material to Mexico. Imports for the week included 1131 tons spiegelisen, 1850 tons ferromanganese and 185 tons ferrosilicon from Germany; 4950 tons iron ore from Cuba.

Birmingham

Feb. 22—The pig-iron market in the Southern territory is dull. The sales being made just now are in small lots and the aggregate far from being satisfactory. A reduction in quotations has been made, No. 2 foundry being quoted at \$12.50 per ton, against \$13, which has prevailed for some time. There are no concessions being made on the \$12.50 per ton rate, reports to the contrary notwithstanding. The Alabama Consolidated Coal and Iron Company during the past week announced the sale of 2500 tons of Clifton iron to the American Locomotive Company on a basis of \$12.50 per ton, No. 2 foundry, immediate delivery practically stipulated. The shipments in the Southern territory are still quite steady though there is no telling when a change will be noted. Reports received here are to the effect that a number of consumers have very little iron on hand but are in no hurry to lay in stocks. The Southern cast-iron pipe com-

cerns have been a help to the manufacturers of pig iron; they are working hard and have orders in hand and in sight that will keep them busy for some time to come. There has been no curtailment in the pig-iron production in the Southern territory as yet, though the same is again under consideration. There is a half-way belief expressed that the change for the better will be noted just after the turn of the new month. There is no iron accumulating in this district, old orders on hand requiring steady shipments and the melt by the pipe plants being good. No change in conditions is noted at the steel plants. The general understanding here is that if there is no improvement in conditions the Ensley plant may be shut down.

Chicago

Feb. 22—The iron market continues unmarked by any significant changes. There is a fair sale of pig iron in small lots, for delivery almost wholly within the next 30 to 90 days, with everybody awaiting general developments of business. Northern No. 2 is nominally quoted at \$17@17.50, and Southern No. 2 at \$13 Birmingham, or \$17.35 Chicago, but cuts of 25 and 50c. prevail, and some lots may bring still less. The market has no fixed prices on any considerable amount of iron.

That the Steel Corporation's reduced prices on its products will do much to stimulate business locally seems to be the sentiment of the market. In the last week as heretofore for several weeks, business in iron and steel products has been quiet. The average melter of pig iron has undoubtedly been conservative about purchases through a variety of causes, chief of which have been tariff agitation and slowness of the country to increase consumptive power. Consumption of iron, though not large, has been fairly steady and remains so. For the future there are a few inquiries for lots of good size and occasionally a sale is made, but furnace agents profess not to be anxious for much business at prices which appeal to melters. Coke continues in light to moderate demand, at \$4.85 for the best Connells-ville.

Cleveland

Feb. 23—There is no change in the ore situation. Shipments from docks are light, furnaces being reluctant to put in stocks in the present condition of the pig-iron market. Ore sellers are not doing anything about prices, as they believe that any buying movement this season will come late.

A few contracts have been made for season ore shipments at the rates which prevailed last year: 65c. from the head of the Lakes to Lake Erie ports; 60c. from Marquette, and 50c. from Escanaba.

Pig iron is dull, sales being small, while the inquiries received are of the tentative order entirely. The market is still based upon \$16.25@16.50 Cleveland, for No. 2 foundry.

Finished material is dull, buyers being, apparently, still at sea on the question of the new reductions in prices.

Philadelphia

Feb. 24—Several transactions in pipe and foundry iron which have been hanging fire since the first of the month will probably terminate in definite orders by the close of the week for Pennsylvania pig irons, because of concessions made by makers. In a general way, very little business is being done. Consumers are mostly low in stocks. They are daily looking for a general concession in prices. A few of the stronger companies prefer to pile iron than lower prices. Somewhat greater activity prevails in the foundries and machine shops. Apart from the general disturbance in the steel trade, conditions are improving and consumers talk in a more hopeful spirit. A few small sales of forge just made show that prices are receding. No. 1 foundry alone holds up well. Basic has undergone a relapse.

Structural Material—The business has consisted mainly of extensions or additions to former contracts. The sharp reductions have not yet been followed by heavy ordering. The market is in a serious condition and a great deal is going on beneath the surface that does not find its way into print.

Scrap—Dealers report very little activity. Some railroad companies are parting with scrap on terms which they refused a few weeks ago. In light scrap a drop of 50c. is noted without much selling.

Pittsburg

Feb. 23—The readjustment in steel prices referred to in last report was decided upon at a meeting held Feb. 18, the form being that of declaring an open market on all steel products, with the exception of standard rails. Each manufacturer was allowed to quote any price desired, and was free to reduce his prices if lower prices should be developed. There had been considerable shading in various products and it was felt that the producers who were disposed to shade would continue to do so as long as any large interests held the umbrella; so that it would be best to put the umbrella away and let it be understood that any cut prices made would be met promptly.

The open market began Feb. 19 and since then the work has been that of developing prices. This work is not half through yet, some lines not having shown any new prices at all, while in others it is not settled that the new prices will

hold. There are prospects, however, that they will. The market developments thus far are summarized below.

Plates and shapes, on which the official price had been 1.60c., but which had been shaded more or less for months, were first quoted at 1.40c., by some large interests, but as somewhat lower prices were named by some, a price of 1.30c. was promptly put out, and this has held. Merchant-steel bars, which had been officially 1.40c., with an inside price to large jobbers and some others of 1.35c., have settled at 1.20c., with no concession. This price has held, although there has been strenuous complaint on the part of large jobbers who have been accustomed to buying at \$1 a ton under the open market. On Feb. 22 the National Tube Company announced to its customers a new list on steel pipe, five points or about \$10 a net ton under the old list, making the official discount on "jobbers' carloads" 80 per cent. off list, against 75 per cent. off list. The trade custom has been to allow large consumers an extra half point, and large jobbers one point, with an extra 5 per cent. This makes the new inside price to jobbers in large lots 81 and 5 per cent. off list. The American Sheet and Tin Plate Company, while making no open announcement, decided to hold to former prices on sheets and timplates, at least for the present. The American Steel and Wire Company announced this morning that on March 1 it would issue a new list of prices, and would adjust prices on all shipments of Feb. 19 and later according to the new list. Billets, sheet-bars and wire-rods have not been touched, absolutely no developments having occurred. Nothing has been done yet in iron products, such as bars and pipe. It is probable that iron pipe will be reduced by about the same amount as steel pipe, keeping it at about the same differential as formerly above steel pipe, this having been two points lately.

There have been no sales of consequence at the new prices. There was no large business hanging over the market, and the new prices have not been tested seriously. Indeed, they have been arrived at largely for the purpose of finding a basis upon which to adjust undelivered tonnages. All shipments made Feb. 19 and later are to be adjusted to new prices as developed, with the exception that a stand has been taken that when the material is for a definite job, on which the contractor's price has already been fixed, no concession should be given.

It is expected that as soon as the adjustment is completed there will be business placed which has been backing up, while in the course of two or three months there will be further improvement in tonnage, and that the second half of this year will show about as large a tonnage as in previous active years.

It is generally accepted that salaries and wages will be reduced, but no definite move is to be made until the full extent

of the price readjustment has been made known.

Pig Iron—The market has been stagnant, the readjustment in steel putting a final quietus upon any disposition to do business. In the pig-iron trade the opinion is strongly expressed that the present developments should help pig iron, by stimulating tonnage, but against this is the prospect that Lake Superior ore will come down. The ore interests insist that no consideration has been given to this subject, and in any event it is quite improbable that they would put out new prices for June, or perhaps July 1. Quoted prices are lower by 50c. in bessemer and by 25c. in basic, foundry and forge being nominally unchanged. We quote, f.o.b. Valley furnace: Bessemer, \$15.50; basic, \$15; No. 2 foundry, \$15; malleable, \$15.50; gray forge, \$14.25.

Ferro-Manganese—The market is entirely nominal at last quotations, \$45.50@46, Pittsburg.

Metal Market

New York, Feb. 24—The metal markets are still in a depressed and rather uncertain condition. Lower prices seem to be the rule in almost all directions.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Jan. 1909.	\$ 7,865,196	\$ 3,412,583	Exp. \$4,452,613
" 1908.	444,200	10,799,484	Imp. 10,355,284

" 1908.	4,148,144	3,621,874	" 526,730

Exports from the port of New York, week ended Feb. 20: Gold, \$1,217,000, chiefly to Argentina; silver, \$1,002,615, to London and Paris. Imports: Gold, \$197,961, from Japan, the West Indies and South America; silver, \$81,642, from Mexico and Panama.

Foreign commerce of the United States, month of January, reported by Bureau of Statistics, Department of Commerce and Labor:

	1908.	1909.
Exports.....	\$ 206,114,718	\$ 156,767,714
Imports.....	84,997,514	103,524,028
Excess, exports.....	\$ 121,117,204	\$ 53,243,686
Add excess of exports, silver.....		882,202
Add excess of exports, gold.....		4,452,613
Total export balance.....		\$ 58,578,501

The gold and silver movement in detail will be found in the table at the head of this column.

Gold—The price of gold on the open market in London has been unchanged at 77s. 6d. for bars; 76s. 4d. per ounce for American eagles. The Bank of England continues to take most of the gold arriving. The Bank of France is out of the market still. In New York there

was some gold shipped to Argentina on London account, but none to Europe.

Platinum—Prices are unchanged, dealers asking \$23.50@24.50 for refined platinum, \$26 for hard metal and \$19@21 for scrap. Business is quiet with demand running rather light.

Silver—The silver market was depressed by some speculative selling—chiefly China sales—and moderate buying only from other quarters. The price is fairly steady at the decline.

SILVER AND STERLING EXCHANGE

24	12½	12½	56½	4.00	3.85	4.67½		
25	12½	12½	56½	3.95	3.80	4.60		
26	12½	12½	56½	4.00	3.85	4.65		

NOTE—Spelter prices given are at St. Louis: New York quotations, Feb. 18-24, were 0.15c. higher than St. Louis.

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—The market has been bordering on demoralization throughout the week. By making radical concessions some lots of copper have found a market in Europe. Home consumers so far are entirely indifferent to the lower prices that have been established; on the one hand, their

business has suffered, and on the other, they are apprehensive of a further decline because they believe that such will be necessary to market the accumulations. The close is weak at 12¾@13c. for Lake copper; 12½@12¾c. for electrolytic in ingots, cakes and wirebars. The average of the week for casting copper has been 12¼@12½c., the price being 12¾c. at the close.

Copper sheets are lower, 17.3@17.5c. for cold-rolled, large lots; 16.5c. for hot-rolled. Copper wire, 15¼c. base, carload lots at mill.

The market in London for speculative sorts declined rapidly the early part of the week, but since Monday it has held relatively steady, the close being cabled at £56 7s. 6d. for spot, £57 2s. 6d. for three months.

Refined and manufactured sorts we quote: English tough, £60 10s.; best selected, £59 10s.@£60 10s.; strong sheets, £71 10s.@£72 10s.

Tin—The London market has had a rather sharp advance during the last few days. There was a good deal of speculative buying, brought about no doubt by advices of shipments from the Straits which indicate a falling off for February and March. The close is somewhat softer at £129 10s. for spot, £131 for three months.

While not much business has been done in the domestic market, prices have followed closely the advance in London and dealers are asking 28¾c. for spot metal at the close.

Tin production of the Federated Malay States in January was 4213 long tons; a decrease of 1322 tons, as compared with January of last year.

Lead—Prices have declined further, and on Feb. 24 the American Smelting and Refining Company recognized the situation by reducing its figure to 4c. New York. The market closes weak at 3.85@3.85c. St. Louis, 3.95@4c. New York.

The London market has been well supported throughout the week and the close is steady at £13 10s. for Spanish lead, £13 12s. 6d. for English lead.

Spelter—Business has been of small proportions and whatever orders come into the market are eagerly competed for. The reductions in the price of iron and steel have so far not increased the demand from galvanizers. The close is weak and lower at 4.60@4.65c. St. Louis, 4.75@4.80c. New York.

Smelters in Kansas and Oklahoma are generally restricting their output by putting furnaces on dead-fire.

The London market is firmer, the close being cabled at £21 15s. for good ordinaries, £22 for specials.

Base price of sheet zinc is 7c., f.o.b. La Salle-Peru. Ill. less 8 per cent.

Other Metals

Antimony—No business is being done, and the market is at a standstill. In the absence of sales prices are nominally unchanged, and we quote 8½¢. per lb. for Cookson's; 8¢. for Hallett's; 7½¢@7¾¢. for ordinary brands.

Aluminum—Business is quiet, with no new developments. Foreign metal is still offered at 22c., New York, but no sales are reported. The Aluminum Company of America quotes 24c. base for No. 1 ingots; 33@34c. base for sheets.

Quicksilver—Business continues small in volume. New York quotations are unchanged at \$45@46 per flask of 75 lb. San Francisco quotations are nominal at \$15 @46 for domestic business and \$43@44 for export. The London price is £8 7s. 6d. per flask, but down to £8 5s. is quoted by jobbers.

Nickel—Large lots, contract business, 40@45c. per lb. Retail, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. These quotations are for spot nickel. The price for electrolytic is 5c. higher.

British Metal Imports and Exports

Imports and exports of metals in Great Britain, month of January, figures in long tons, except quicksilver, which is in pounds:

	Imports.	Exports.	Excess.
Copper, 1908.....	12,842	6,089	Imp. 6,753
Copper, 1908.....	12,212	6,543	Imp. 6,669
Tin, 1908.....	3,564	2,067	Imp. 1,497
Tin, 1908.....	3,381	2,371	Imp. 1,010
Lead, 1908.....	16,618	2,765	Imp. 15,853
Lead, 1908.....	19,034	4,955	Imp. 14,079

Spelter, 1908.....	7,664	459	Imp. 7,205
Quicksilver, lb., 9,992	60,746	Exp. 50,754	
Quicksilver, '08	18,376	234,055	Exp. 215,680
Ores:			
Tin ore and con.	1,305		Imp. 1,305
Tin ore, 1908.....	2,006		Imp. 2,006
Pyrites, 1908.....	64,636		Imp. 64,636
Pyrites, 1908.....	97,073		Imp. 97,073

Copper totals include metallic contents of ore and matte. Exports include re-exports of foreign material. Of the imports in 1909 the United States furnished 15 tons copper matte, 1596 tons fine copper, and 2746 tons lead.

Zinc and Lead Ore Markets

Joplin, Mo., Feb. 20—The highest price paid for zinc sulphide ore was \$40 per ton, the base price ranging from \$35 to \$38 per ton of 60 per cent. zinc, stronger at the week-end—\$36@38, with increased demand for all grades. Zinc silicate sold at \$26 top, on a base of \$19@22 per ton of 40 per cent. zinc. The average price, all grades of zinc, was \$34.72. Lead opened weak at \$50, declining to \$49 and \$48, with a falling demand, much of the ore shipped here from previous purchases.

The weather is admirable for outputting for the season, and the mine owners are again adjusting the wage scale and expense account to the market conditions,

saving a panicky margin of profits to some, while others are merely trading even.

NOTE.—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

Platteville, Wis., Feb. 20—The highest price paid for zinc ore this week was \$38 per ton; the base price for 60 per cent. zinc was \$36@37 per ton. There was less than the usual amount of high-grade ore available for competitive purchase, a number of roasting plants being idle. One car of lead ore brought \$48 per ton; the base price for 80 per cent. lead was \$46 per ton.

In addition to the above there was shipped to the American Zinc Ore Separating Company from Rewey, 324,460 lb.; from Benton, 267,800 lb.; from Lancaster, 92,000 lb.; from Platteville, 168,820 lb. Shipped to the Joplin Separator Works, from Hazel Green, 305,400 lb.; from Linden, 76,670 lb. zinc ore.

Chemicals

New York, Feb. 24—Business continues quiet, and the situation is not changed. The general tendency seems to be to buy for immediate use only.

Copper Sulphate—Only a moderate business has been transacted. Prices remain, however, the same as last week at \$4.60 per 100 lb. for carload lots and over; \$4.85@5 per 100 lb. for smaller parcels.

Nitrate of Soda—Trade remains easy. Prices are unchanged, spot nitrate being quoted at 2.15c.; for future business, 2.12½c. is asked.

Mining Stocks

New York, Feb. 24—The reduction in steel prices—which in the true light is really a bull argument—was taken up by the bears as a reason for forcing a general reduction. Beginning with United States Steel a sharp decline set in, which involved not only the industrials, but also Amalgamated Copper and finally many railroad stocks. The market was generally excited after the holiday on Monday, and on Tuesday the dealings were the heaviest of the year. The quotations were lower all around at the close, with the market still tending downward, and indications of a bear market likely to last for a time, with occasional rallies possible.

The Curb followed the course of the Stock Exchange, with general declines in quotations, some of a sharp order. There was, however, a degree of conservatism not always shown on the Curb. The copper stocks generally were heavy and rather weak, with much selling and a good deal of liquidation. In other mining stocks trading was not so heavy, but there was a general downward tendency manifest. The close did not point to an immediate recovery.

Boston, Feb. 23—Mining-share prices are the lowest of the year and considerably below the high levels of 1908. Each day the past week has seen lower prices, as a rule. Certain stocks have had their ups and downs and periods of activity, but prices are considerably off in the week's time. This is due to the fact that copper has weakened and the cut in the prices of steel products has had a depressing effect also.

Even the knowledge that A. S. Bigelow and associates will deliver to the Calumet & Hecla people this week something like 125,000 shares in the Osceola, Tamarack, Ahmeek, Isle Royale, Seneca and Laurium mining companies, could not stem the tide in today's selling and liquidation.

Calumet & Hecla directors have de-

The Curb has been active and prices are slightly lower. Trading in Southwestern Development has been ordered to cease on the Curb temporarily.

*EX. DIV. (EX. RIGHTS)

The Standard Consolidated Cyanide Mill

The Pulp, after Crushing in Cyanide and Passing over Amalgamation Plates, Is Treated by Mechanical Agitation Tanks and Moore Filters

B Y S . F . S H A W *

The ore from the mines is hauled to the Standard Consolidated Mill, Bodie, Cal., by mules in trains of five cars, each having a capacity of $1\frac{1}{4}$ tons, to an inclined track over which the cars are hoisted by a belted hoisting engine and dumped into a 100-ton bin. From the bin the ore is fed to a 9x15-in. Blake crusher, falling into another bin from which it is delivered to the stamps by Challenge feeders. There are four batteries of five stamps each; the stamps weighing 1000 lb., drop 96 to 106 times per minute, and have a drop of 4 to 6 in. The consumption of metal in the shoe is 0.63 lb. per ton of ore, and in the

When the ore contains any appreciable quantity of sulphides, which is rarely, the pulp from the amalgam traps flows to four 6-ft. Frue vanners after which it is elevated in three lifts by Frenier sand pumps to the flume in which it flows to the cyanide plant.

A 4x6x12-ft. sump receives the pulp from the flume and the material is elevated by a No. 2 Carson centrifugal pump to two 48-in. conical spitzkasten. The underflow from the spitzkasten flows through a launder beneath the feeder which delivers into the same launder tailings from the old stamp-mill ponds.

AGITATION APPARATUS

The overflow from the spitzkasten flows through a 4-in. pipe to the agitation vats of which there are five, 18 ft. in diameter and 15 ft. deep, and five 20 ft. in diameter and 11 ft. deep. Seven hours are required to fill a vat. Upon starting to fill, the mechanical agitators are thrown on and agitation is continued for 12 hours after the vat is filled. Air is also supplied during the agitation as long as is possible, depending upon the amount that can be delivered by the compressors. The pulp then is allowed to settle for about 40 hours during which time the average

BODIE, CAL., STANDARD CONSOLIDATED MILLS IN BACKGROUND

die 1.16 lb. Crushing takes place in sodium cyanide solution equivalent to 0.12 per cent. potassium cyanide, the pulp being discharged through a 30-mesh punched screen. The pulp falls on a lip plate 18 in. by $4\frac{1}{2}$ ft.; then on two 4x8-ft. plates, and thence on two 4x4-ft. plates. The plates are of sheet copper, $\frac{3}{16}$ in. thick and are plated with silver amounting to 2 oz. per sq. ft. An amalgam trap is placed at the end of the lower plate.

These tailings are elevated in two-ton cars over a trestle to a 50-ton bin dumping on a grizzly 7x14 ft. with $1\frac{1}{4}$ -in. openings. The material remaining on the grizzly is composed largely of pieces of clay which fall into, and are broken up by, a mixing pan at the foot of the grizzly, after which it joins the underflow from the spitzkasten and is carried directly to a 5x22-ft. Gates tube mill, driven at 24 r.p.m. The material discharged from the tube mill flows to the 4x6x12-ft. sump previously mentioned.

settlement is 26 per cent. of the total height. Decantation then begins and all of the clear solution is drawn off to the strong solution tanks. The sweeps are then started, and after the pulp is well mixed, it is pumped by a 3-in. centrifugal pump to the filter vats. There are two of these pumps, one for each set of five agitation vats. Pipes 4 in. in diameter convey the pulp from the vats to the pumps and 3-in. pipes from the pumps to the filter vats. The 4-in. pipes are too small and frequently become choked.

*Mining engineer, Pasadena, Cal.

The Moore vacuum filter press used has two baskets, each containing 45 leaves. The two filter vats and also the wash-solution tanks are each 24 ft. in diameter and 7 feet deep. These tanks were formerly used as percolation vats. During filtration a vacuum of 13 in. is maintained, although at first the relief valve on the pumps must be opened so as to obtain a vacuum of only 7 or 8 in., as the flow of solution is too great for the pump motor to handle. The greatest vacuum that can be obtained at this altitude is 21.7 inches.

The pulp in the filter vats is kept in agitation by sweeps operated by a shaft passing through the bottom of the vats. Air is also used, drawing the pulp from the bottom of the vat and discharging over the edge at the top. These filter vats frequently become stopped by the settling of the coarser sand to the bottom, especially when any stoppage makes it necessary to throw off the sweeps; as a rule the vats need to be sluiced out once a month.

After a cake is formed the basket is raised and carried to the wash tank and

flow to the zinc precipitation boxes of which there are three rows for the weak solution, each row having 20 compartments, and for the strong solution six rows having nine compartments and four rows of 10 compartments. There are also in the zinc room 12 rows of boxes, each having 10 compartments, which have not yet been put into service. The strong solution before precipitation averages 0.11 oz. gold and 0.3 oz. silver, and after precipitation 0.003 oz. gold and a trace of silver. The weak solution before precipitation averages 0.06 oz. gold and 0.27 oz. silver, and after precipitation 0.0056 oz. gold and a trace of silver.

The barren solutions are discharged into sump tanks having 540 cu.ft. capacity for the strong, and 750 cu.ft. for the weak solution. A No. 3 Gould centrifugal pump driven by a 15-h.p. motor elevates the barren solutions to the storage tanks above the plant, aggregating 4600 cu.ft. capacity for strong and 1230 cu.ft. for the weak solution. For every ton of ore treated two tons of strong solution and 0.7 ton weak solution flows through the zinc boxes.

raising and lowering the basket, and one for driving the 12x12-in. wet vacuum pump. A 20-h.p. motor drives the agitators in five of the agitation vats and a 3-in. centrifugal pump which elevates the pulp from these vats to the filter vat.

During the time that I was in charge of the plant the tailings from the stamp mill flowing to the tube mill for regrounding averaged 0.39 oz. gold and 0.94 oz. silver, which, upon reaching the agitation vats, showed an apparent extraction of 70 to 75 per cent. The tailings fed from the old stamp-mill tailings dump averaged 0.29 oz. gold and 1.8 oz. silver. Sizing tests on material from the stamp mill averaged as follows:

+40 mesh	9 0 per cent.
40-60 mesh	17 5 per cent.
60-80 mesh	14 0 per cent.
80-100 mesh	12 0 per cent.
100-200 mesh	15 5 per cent.
-200 mesh	32 0 per cent.

The material from the tailings dump averaged as follows:

+40 mesh	8 7 per cent.
40-60 mesh	23 7 per cent.
60-80 mesh	29 6 per cent.
80-100 mesh	8 4 per cent.
100-200 mesh	19 3 per cent.
200- mesh	19 3 per cent.

CYANIDE MILL

TWENTY-STAMP MILL

washed in a weak solution of 0.07 per cent. cyanide. After washing, the cakes are discharged from the filter by compressed air introduced inside of the leaf, into a hopper having a bottom sloping 45 deg., and are sluiced to the tailings ponds. The average time of a cycle is as follows:

Making cake	150 min
Moving to wash vat	12 "
Washing, weak solution	166 "
Moving to discharge	10 "
Discharging	10 "
Moving to filter	12 "
Total	6 hr.

The thickness of the cake averages 0.83 in. and when discharged it contains 27 per cent. moisture. The loss of cyanide due to this contained moisture is 0.38 lb. per ton of ore. These two baskets handle 110 tons of dry pulp per day.

PRECIPITATION

The solutions from the filter are discharged into gold solution tanks aggregating 4040 cu.ft. capacity for the strong solution, and 1780 cu.ft. for the weak solution. From these tanks the solutions

The stamp mill is supplied with solution by a 5x8-in. Knowles triplex belted pump elevating to a supply tank at the mill having a capacity of 3100 cu.ft., from which it is drawn to the batteries.

CLEAN-UP

A clean-up is made twice a month. The precipitate which passes through a three-mesh screen is hauled in tubs by wagon to the acid room where the unconsumed zinc is dissolved with sulphuric acid. Nine washings and decantations are then given to remove the acid, after which the precipitate is filtered on a blanket ejector using steam to obtain a vacuum. It is then dried, mixed with borax and soda, melted and cast into bars.

A 75-h.p. Stanley induction motor drives the tube mill, mixing pan, Rix air compressor, Knowles triplex pump, filter-vat agitators, and the agitators in five of the agitation vats. This motor is supposedly about 50 per cent. overload.

The Moore filter-press frames are each supplied with two 10-h.p. motors, one for

The spitzkasten overflow going to the agitation vats sized as follows:

+40 mesh	0 5 per cent.
40-60 mesh	4 5 per cent.
60-80 mesh	7 1 per cent.
80-100 mesh	14 9 per cent.
100-200 mesh	24 8 per cent.
200- mesh	48 2 per cent.

The discharge from the filter press sized as follows:

+40 mesh	0 3 per cent.
40-60 mesh	1 8 per cent.
60-80 mesh	4 1 per cent.
80-100 mesh	6 8 per cent.
100-200 mesh	21 9 per cent.
200- mesh	61 1 per cent.

The average apparent extraction is 88 per cent. gold and 57 per cent. silver. Owing to the tonnage from both mine and tailings dump being estimated by volume, no exact extraction percentages can be given. There is probably an appreciable loss in the clean-up owing to inadequate facilities in the zinc and clean-up rooms.

The tube mill is lined with plates of soft metal 1 1/2 in. thick by 8 ft wide, lasting 10 months with a consumption of 0.5 lb metal per ton of ore. The pebble consumption is about 3 lb. per ton. Figures

for consumption of chemicals per ton of ore are as follows: Mercury, 0.22 oz.; cyanide equivalent to 1.16 lb. potassium cyanide; zinc oxide, 0.6 lb.; lime, 7.5 pounds.

The labor for two shifts of 12 hours is as follows: Two tube-mill men who attend to the tube mill, tailings feeder, compressor, triplex pump, and zinc shaving lathe; one tailings feeder at night; two basket men attending to the Moore filters, vat agitators, and the pulp, centrifugal pumps; one zinc-room man, who attends to the zinc boxes and clean-up; one night foreman; and one general foreman. Owing to the present arrangement of tanks, pipes, etc., two mechanics are constantly required for repair work.

I am indebted to Arthur Faust, manager of the Standard Consolidated Mining Company, for many of the figures used in this article.

Mine Legislation in California

SPECIAL CORRESPONDENCE

One of the senators in the State legislature, now in session at Sacramento, has discovered that there is no State mining law in California, and has introduced a bill regulating the conditions under which mining claims may be acquired. This gentleman states that there are no statutory provisions upon the subject of mining in the State and that one may stake out a claim without recording it or putting up monuments. All that has to be done is to find the ore. Upon this announcement the daily papers take the matter up and agree that it is wonderful that the miners could have got along so many years without a specific State law, there never having been any. The fact is, notwithstanding these statements, that some years ago the legislature adopted certain mining laws relative to the taking up and recording of claims, but after a few years the law was found to be useless and was repealed. All that the law really did was to establish certain fees for certain officials, without benefiting the mining industry in the least. The Federal law was sufficient in all respects and remains law in this, as in other States. Upon the acquisition of this State and the exciting results produced by the discovery of gold, the Government found itself fettered by an ancient and illiberal law of reservation. The miners who came to California from all parts of the world adopted a system of mining regulations entirely voluntary. The system was not only adopted, without the authority of the Federal government, but all mining on public lands was forbidden. Subsequently the laws adopted by the miners became the laws of the State. The State courts followed the same principle, naturally adopting the code presented by the miners. While this

code was in force Congress passed the act of July, 1866, which in effect confirmed the laws adopted by the miners of California.

Before this there has been a number of acts passed by the State legislature relating to mines, but mainly in the direction of taxation, especially of foreign miners. The first American mining law, that of 1866, was passed while Senator Conness of this State, who died last week, was chairman of the Committee of Mines in the Federal Senate, and was introduced by Mr. Sherman, of Ohio. That act remained in force until May 10, 1872, when the act at present in force was adopted by Congress. The miners of this State, as elsewhere, have acquired their titles and conducted their operations under this law. It has been interpreted in all its phases by the courts and seems to answer every purpose, so there does not seem to be any necessity of a special law for the State of California. Doubtless if one is adopted by the legislature it will benefit certain officials by fees for recording, etc., but there is little doubt that the miners do not want any new laws on the subject.

Another innovation is that proposed by an assemblyman from Nevada county, which is a mining county, by the way. His bill provides for a State inspector of mines who shall visit all mines in California to examine machinery and other appliances and inspect shafts, drifts and other underground works. If the inspector rules that anything is dangerous to life, the owners are notified and they must apply certain remedies. The inspector is only to get \$2400 per annum and his two assistants \$500 each. This seems an absurdity. No competent men could be obtained for such salaries and there would be much chance of blackmail against the mineowners. This looks like a miners' union bill, but as several measures of similar object have been killed in previous legislatures, it is probable that this one will be also. The men from the mining counties will unite to prevent any such legislation. There are not half a dozen coal mines in the State and the gold mines are not subject to explosions or accidents from which great loss of life may result.

Another measure which is to be discussed in the legislature is a method of regulating by law the system of boring oil wells. It is proposed to form oil districts, similar to the reclamation districts, which shall have the power of electing trustees to make laws governing the boring of wells and other vital matters, and to penalize violators of the regulations if necessary. It is desired to make the drilling records public, instead of keeping them secret from other drillers in the same district. With the drilling record or log made public in oil districts there would be less danger of coming upon un-

expected water strata and consequent flooding. The new bill makes it compulsory to shut off by proper means all such water strata encountered.

Los Lamentos Mine

The Los Lamentos mine, 55 miles from Ahumada, Chihuahua, Mexico, on the Mexican Central Railway, is at present producing from 10 to 20 tons of zinc-silver-lead ore per day. George B. Squires, formerly of the El Paso smelter, is manager. Water is hauled 9 miles. Sufficient fuel for all needs are found close at hand. The mountain is steep and sinking will not be necessary until a depth of 500 ft. is attained. All the work is now done from adit levels.

GEOLOGIC CONDITIONS

The Los Lamentos mountains, in which the mine is situated, form a small range in the center of a plain 60 miles wide and 200 miles long. These mountains are made up, of limestone and it is probable that they are in the same Cretaceous belt in which are found the Mexican mines of Mapimi, Vallardena, Sierra Mojada, Almoleya, Rio Florida, Naica, Santa Eulalia and others toward the south. In most of these districts, notably Santa Eulalia, great bodies of zinc ore occur in the limestone in close proximity to the lead-silver ores, and such is the case at Los Lamentos.

The surrounding country is eruptive. Float is found in the valleys on each side of the range; this doubtless had its origin in the adjoining ranges, which are formed of basalt, granite, porphyry and lime. The limestones of the Los Lamentos strike in a generally east-west direction, but mineralization is encountered chiefly in north-south folds of the rock. The orebodies are found where the fracturing is most pronounced. Natural caves are characteristic of the district.

THE ORE

When the present operators began work on the mine it was thought that the ore was entirely silver-lead, but soon it was found that for every ton of lead-silver ore there was mined about seven tons of zinc ore. The zinc ore so far mined is oxidized, no sulphide as yet having been encountered. The lead-silver ore runs high in iron and low in silica and makes a desirable smelting material. The zinc ore carries about 43 per cent. zinc.

The ore is packed from the lower workings by peons in *zurrones* (rawhide buckets of from 100 to 200 lb. capacity each). The ore from above the adit levels, however, is wheeled out in barrows to the loading patio.

The mine has the appearance of stability. Development work is based on the hypothesis that there is here a regular system of ore deposition such as occurs throughout this lime belt.

Mining and Milling Florida Phosphates

The Mineral Is Mined by Means of Monitors, Dredges or Steam Shovels, and After Crushing, Screening, Washing and Drying Is Ready to Ship

B Y C . A . S T O N E *

The phosphate deposits of Florida are divided into three classes, hard-rock, land-peggle, and river-peggle deposits. Land-peggle deposits are the most extensive, and the phosphate rock mined in the districts where these are found ranges in size from that of very fine bird-shot up to pieces approximately the bulk of an egg. The method of recovery is as follows:

When a deposit has been located, the

were taken, that of the Pierce Phosphate Company, Bartow, Fla., a 2½-in. stream is thrown by the gun, under a pressure of 100 to 125 lb. per sq. in. at the pump. There is nothing regular about the deposits, as will be seen from the illustration, and the scene of operations is being constantly shifted.

From the sump hole the material is lifted by means of two to-in. centrifugal

operating at 450 to 600 r.p.m. Fig. 5 is a closer view of the washer shown in the preceding illustration, and with Fig. 6 it is typical of those erected in the land-peggle districts, for all are of the same general construction.

The matrix washed from the mine, carried by about seven times its weight of water, discharges from the pipe line at the top of the washer and is spread over a

FIG. 1. STEAM SHOVEL LOADING PHOSPHATE ROCK INTO CARS IN LAND-PEBBLE DISTRICT

FIG. 2. DREDGE USED IN WORKING RIVER-PEBBLE DEPOSITS

FIG. 3. WASHING PHOSPHATE PEBBLE INTO SUMP HOLE

FIG. 4. LIFTING MATERIAL TO WASHER FROM SUMP HOLE BY MEANS OF CENTRIFUGAL PUMPS

overburden, varying in thickness from 4 to 25 ft.—seldom more—is usually removed by means of a steam shovel. Then a stream of water from a hydraulic “gun,” Fig. 3, is turned upon the deposit and the pebble matrix washed down into a sump hole, shown in Fig. 4 at the right of the gun. At the mine where the photographs illustrating this part of the article

gravel pumps to the top of the washer, appearing in the upper left-hand corner of Fig. 4, a distance of about 80 ft. The first of these pumps is located at the bend of the pipe line, near the center of the illustration, and discharges into the other pump installed at the foot of the washer. Throughout the pebble district to-in. centrifugal pumps are used almost exclusively for this service. Each of those above mentioned is run by an induction motor

flat screen. Thence it passes to a revolving screen, where the lumps of clay, large pieces of rock and other foreign matter are removed; the material is then discharged into a pair of 24-ft. log washers. From these the partially cleaned rock is fed to another revolving screen, which in turn discharges to a flat screen, from which the material passes to a wet bin. Rejections from the various screens are separately treated in a sluice box, marked

*Baltimore, Md.

SB in Fig. 5, in order to recover the finer particles contained in the refuse. Throughout the entire operation fresh water at a pressure of from 50 to 70 lb. per sq.in. is used to aid in washing the rock and clay from the matrix.

From the wet bin, shown in Fig. 6, directly over the railroad track, the rock is drawn off into side- or bottom-dump cars and hauled to a central drying station, illustrated in Fig. 7, where the material is elevated by means of a grab bucket, having a capacity of about two tons, and either emptied into wet bins,

bins, dryer house, conveying system and dry bins are very clearly shown in the end- and side-elevation drawings, Figs. 9 and 10.

For a panoramic view of one of the leading phosphate company's operations the reader is referred to Fig. 8. Here *A* represents the mine ready for opening, *B* the washing plant, *C* the pump house, *D* the wet bins, *EG* wet rock (temporarily stored under the telepher track *F*), *H* the dryer house and stacks, *I* a strip of ground being mined, *J* an orange grove soon to be uprooted, *K* the cross-conveyor from

Shaw, engineer of the phosphate company, and the engineers of the Link-Belt Company, of Philadelphia.

In the phosphate districts one finds power plants of the most approved construction, so far as equipment is concerned. The power plant of the Prairie Pebble Phosphate Company consists of seven 300-kw. polyphase generators for alternating current, each belt driven by a pair of three-cylinder Diesel oil engines operating at 164 r.p.m. All of the machinery in the plant mentioned, including pumps, screens, dumps, elevators, tele-

FIG. 5. VIEW OF WASHER SHOWN IN UPPER LEFT-HAND CORNER OF FIG. 4

FIG. 6. ANOTHER WASHER TYPICAL OF THOSE RECENTLY ERECTED IN LAND-PEBBLE DISTRICTS

FIG. 7. CENTRAL PLANT FOR DRYING PHOSPHATE ROCK

FIG. 8. PANORAMIC VIEW OF A LEADING PHOSPHATE COMPANY'S OPERATIONS

or if the latter are full, temporarily dumped on a pile outside.

From the wet bins the rock is fed into 6x60-ft. rotary dryers; each pair of these discharges into an elevator. The rock as it goes to the dryers contains approximately 15 per cent. moisture, and when discharged contains only 2 per cent. moisture. The rock is discharged from the elevator into a hopper scale and then passes to a cross-conveyor, marked *CV* in Fig. 7, which takes the rock to a conveyor running lengthwise of the dry bin, whence it is drawn off into covered cars for shipment. All of the details of the wet

the wet bins to the dryer house, *L* the dry storage bins, *M* the stack of the power plant, *N* the track for carrying away strip-pings, *P* the wet bin of the washing plant, and *Q* a reservoir from which rock has already been mined.

An idea of the value of the output may be gained from the statement that at the time this photograph was taken the pile of rock *EG* was worth \$125,000 on the spot. Fig. 11 is a plan showing the arrangement of the buildings of the main plant, furnished by courtesy of the Pierce Phosphate Company. This was designed by H. L. Pierce, president, and A. D.

phers, conveyers, air compressors, driers, etc., are driven by motors, either singly or in groups, these being of the standard squirrel-cage induction type.

Large quantities of clean water are required for washing the phosphate, so that during a dry season the miners are put to a great deal of trouble, and sometimes they are unable to operate in consequence of the scarcity of water. This led to forcing the matrix, by means of centrifugal pumps, through pipe lines from the different mines to a central washing and drying station; but experience has shown that it is more economi-

cal in the long run to have the washer located at the mine, even though the washed rock has to be hauled to a central drying plant.

Methods of operation in all of the districts are practically the same as described in this article, with the exception of the

f.o.b. cars at the mines. Among these companies in Florida the largest operators are the Prairie Pebble Phosphate Company, of Mulberry; Dunnellon Phosphate Company, of Rockwell; Pierce Phosphate Company, of Pierce; Dutton Phosphate Company, of Gainesville; Cummer Lum-

Gold in Rhodesia

The general impression that Rhodesia is a high-grade goldfield is disproved by the report of the Rhodesia Chamber of Mines for the year ending March 31, 1908, which shows that prior to April, 1908, only £10,000,000 had been obtained from the 6,300,000 tons of ores crushed; in other words the ore has yielded only 30s. 11d. per ton, or less than the average obtained from the ore now treated on the Rand. For the year ending with March the ore yielded an average of 27s. 9d., or \$6.66 per ton. The fall in grade is due to the low grade of ore treated at a profit by tributaries and by the lower-grade ore treated by the larger companies owing to the considerable decrease in cost of mining effected in the last two years.

The cost of mining and milling at the Simmer & Jack property on the Rand, South Africa, during the year ending June 30, 1908, was 16s. 2.646d. per ton of ore crushed. Mining cost 8s. 7.3d. per ton; pumping, 3.474d.; transportation, crushing and sorting, 6.08d.; stamp-milling, 1s. 4.337d.; tube-milling, 7.668d.; sand treatment, 1s. 2.262d.; slime treatment, 5.681d.;

FIG. 9. END ELEVATION SHOWING PRINCIPAL DETAILS OF A PHOSPHATE DRYING AND STORAGE PLANT

FIG. 10. SIDE ELEVATION OF PLANT SHOWN IN FIG. 9

fact that the hard-rock phosphate, which is found in pieces up to several tons in weight, has to be excavated, crushed and elevated to the washer, and that in the river-pebble district a dredge takes the place of steam shovel and hydraulic gun.

Fig. 1 shows one of the steam shovels at work, and Fig. 2 a dredge, the latter carrying its own washing plant, quite similar to those used in the land operations. Dredges are sometimes used in the hard-rock and land-pebble districts where pockets of the phosphate are found under water.

The hard rock yields from 77 to 80 per cent. phosphate of lime and the pebbles run 62 to 70 per cent. The cost of getting out the former varies between \$2 and \$2.50 per ton, and that of the latter from \$1.50 to \$2.25 per ton. Drying is done at an expense of 14 to 22c. per ton. For fuel wood, coal, or oil are used, this being determined largely by local conditions.

Rock for domestic use is shipped to the fertilizer plants, mainly for combination with other ingredients forming by-products of various industries, such as offal from the packing houses. For foreign consumption the washed and dried rock is loaded mainly at Port Tampa, Fernandina and Jacksonville, Fla., where extensive dockage and loading facilities have been provided, or at Savannah, Ga.

The phosphate industry in Florida, where the most extensive deposits are found, is controlled by 12 companies, four in the hard-rock and eight in the pebble districts. The total phosphate output in 1907 was 1,350,000 tons, valued at \$6,750,000

FIG. 11. PLAN OF A TYPICAL PHOSPHATE DRYING AND STORAGE PLANT

ber Company, of Jacksonville; Camp Phosphate Company, of Istachhatta; and Swift & Co. Recently a combination of the principal interests has been entered into for the purpose of more economically handling and marketing the future product of the mines.

general charges, 1s. 3.371d.; development redemption, 1s. 8.018d.; total, 16s. 1.091d. per ton; renewals and replacement of plant, buildings, etc., 1.555d.; grand total, 16s. 2.646d. per ton of ore crushed. During the year 785,310 tons of ore were treated, yielding £1 12s. 3.768d. per ton.

Close Sizing of Dry Finely Crushed Ores

The Construction and Advantages of the Vibromotor Sizer for Dry Ores Are Discussed, and the Results of Tests on it Are Given

BY E. GOODWIN STEELE*

No other element is more essential to successful ore concentration than perfect sizing of the ore prior to treatment by suitable jigs, tables or other concentrating machinery, and the truth of this is becoming more and more apparent to the up-to-date millman.

Close sizing is especially important in the treatment of what is usually termed the refractory ores; for instance, either lead or copper ores carrying much zinc, or zinc ore with considerable iron or copper in it. On account of the slight difference in specific gravity of these minerals it is usually necessary to crush these ores to 18 mesh, or finer, to free the minerals.

Simple as the sizing problem seems to be at first sight, the ordinary methods of screening or, more properly speaking, sizing now generally employed, gives poor results when the attempt is made to size accurately in the finer sizes.

Screens for dry sizing can be divided into three classes: screens that have the screening surface set on an angle of approximately 45 deg. from the horizontal and which depend on gravity alone to keep the pulp moving over them; screens that have screening surface set at a much less angle, and which have a mechanical motion to assist gravity in moving the ore; and finally screens that have the screening surface horizontal and which depend entirely on mechanical means to prevent the screen cloth from blinding.

Each of the three general types has advantages, although for perfect sizing the nearer to the horizontal the screening surface is set, the nearer in size will be the ore particles to the openings in the screen cloth. For instance, when a screen cloth is set at an angle of 45 deg., the horizontal wires cover a portion of the next strand below, and for this reason, it is necessary to use a much larger mesh cloth than the product desired. This tends to slightly prolong the life of the screen, and if it was possible to cause each of the ore particles to strike the cloth at exactly the same angle, close sizing could be accomplished. This is impossible, however, and therefore, the heads show an unsized product.

On screens set at a less angle, it is necessary to have a jar or bump not only to move material along them, but also to prevent the screen cloth from blinding. This sets up a vibration in the screen,

which in time, causes the wires of the cloth to crystallize and break at the inside edges of the screen frame. This vibration of the screen cloth also causes the pulp to travel faster over the middle of the frame, or over the middle of each longitudinal section, than at the edges, and produces a thickening of the pulp along the central line of travel. These lens-shaped streams, being thicker and

minute particles of ore travel entirely across a screen without once coming in contact with its screening surface.

When studying the various methods of sizing dry material employed in ore milling, as well as in the other arts, it was found that in the flour-milling industry a much higher state of perfection had been attained. While, of course, the evolution of this art to its present plane was

FIG. 1. SUTTON, STEELE & STEELE VIBROMOTOR ORE SIZER

traveling more rapidly in the center, carry the small and lighter particles on their surface, and many of these fine particles are thus carried over into the oversize bin. This type of screen, also, usually has a vertical vibration of the screen frame which produces an upward current of air through the screen cloth on the down stroke, thus floating the lighter particles on the surface of the streams and preventing them from reaching the screening surface. Indeed, I have seen

reached upon an entirely different class of material, yet it is interesting to note that in the early methods employed, reels and vibrating screens were used and that these machines have been displaced by the more efficient gyratory bolter, which has been adopted by the leading millers of today. Success in fine sizing in the flour-milling industry was attained by the use of machines of the gyratory type and flour milling is today far in advance of its sister art, ore milling.

*Secretary-treasurer, Sutton, Steele & Steele, Dallas, Texas.

GYRATORY SCREENS

Fine sizers of the gyratory type have many advantages over vibrating or pulsating screens. There is no vibration of the screen cloth, which is set perfectly horizontal and consequently permits the utilization of the full size of the screen openings. The machine requires less power as the motion when once set up is not interrupted or reversed. There is absolutely no vibration imparted to the supporting framing and the means for preventing blinding of the screen cloth does not wear the cloth or cause a vibration of the screen wires. This accounts for the large capacity of the Sutton, Steele & Steele vibromotor ore sizer, a name given to it on account of its peculiar drive.

This machine was designed along the lines of the gyratory flour bolter with horizontal sieves, though made much stronger and heavier for ore sizing. Fig. 1 shows a view of the exterior of the sizer and method of supporting the body of the machine, which is hung on 24 one-inch wooden reeds.

The body of the sizer is made in eight sections with a door to each section. The screen frames are arranged in descending spirals, each frame being set perfectly level but dropped slightly below the one preceding it in the same spiral. The pulp travels easily and smoothly without pounding and its condition is not disturbed from the feed to the discharge of the system. Any arrangement of the screen frames can be made and any number of products taken from the machine up to 17. By having more than one feed inlet, the machine can be arranged as a duplicate or triplicate sizer, each section delivering the same mesh products or they may differ from each other as may be desired. This flexibility permits of the sizer being especially designed for the material, or ore, to be sized. After careful hand-sizing tests have been made, a flow-sheet for the sizer is drawn to suit the conditions and more or less area of screen cloth is given to each size as may be required. The sizer is made in two sizes; one rated at 50 (No. 3½) and the other at 75 tons (No. 4½) per 24 hours. The 50-ton machine has screen frames having an area of 124 sq.in. each, or a total of 117 sq.ft. of screening surface, and the 75-ton sizer has 169 sq.in. in each screen with a total screening surface of 178 sq.ft. The fact that each square inch of this surface is kept open and active at all times accounts for the high efficiency of the machine.

Each screen frame has a coarse mesh (¼ in. openings) cloth on its under side (Fig. 2) and between this screen and the upper screening cloth is placed a small circular brush. This brush, which is about 2 in. in diameter, has three small bosses or spurs, on its under side and as these

spurs travel over the coarse mesh screen, they give the brush a continual tipping motion, which causes the stiff bristles to push upward the ore particles that are blinding the screen cloth. As this brush travels continuously over the entire under side of the screening surface blinding is effectively prevented. This permits of very fine sizing; as fine as 200-mesh cloth can be used in the machine without the slightest blinding of the meshes.

THE ROTATING MECHANISM

The driving pulley is carried on a short vertical shaft above or below the sizer as may be most convenient. Between this shaft and the main shaft of the sizer is a short intermediate shaft with universal couplings of a simple design. When the machine is running, the connecting section of the shaft revolves exactly in line with the shaft on which the driving pulley is placed, and the flexible couplings, therefore, act like common couplings; the uni-

FIG. 2. TOP VIEW OF SCREENS USED IN THE VIBROMOTOR ORE SIZER

versal couplings being used simply to allow the machine to take its own motion in starting and stopping, as when running, it centers itself with the driving shaft.

The intermediate driving shaft is attached to the sizer shaft at approximately 1½ in. from its center, which is half the usual throw of the machine. To the sizer shaft above and below the body of the sizer are attached heavy counterbalances, which exactly balance the weight of the sizer and its load. A proper amount of weight is put in the counterbalances when the machine is set up in the shop and these weights never need changing nor adjusting, unless it is desired to increase or diminish the throw of the machine. This is done by simply taking out or putting in small iron plates. If the load varies the machine will take care of the variation automatically as it is absolutely self-balancing and requires no attention whatever from the operator in this respect. The vibromotor drive causes the sizer to travel in a true circle, approximately 3 in. in diameter, with absolutely no vibration, at 105 r.p.m. About 2 h.p. is required to

start the machine, and ½ h.p. to run it after it is started.

The pulp is fed to the sizer by gravity from a small bin through a chute having a small metal box attached to it. This box is placed to one side of the opening in the sizer so that the pulp accumulates in it up to the angle of rest. When the machine is started, the gyrations crowd the pulp over to the sizer inlet, the feed being regulated by the distance from the end of the chute to the bottom of the feed box. This automatically cuts off the feed when the sizer is stopped. The pulp, after entering the sizer, immediately begins its travel around the descending spirals until it has passed over the desired number of screens when the first oversize enters a spout in one of the doors, there being two spouts in each door. The undersize continues its travel around the sizer until the required number of oversize products have been taken out; the final fines pass out at the bottom of the machine. Each oversize product after entering the chutes in the doors drops down to the bottom of the machine, re-enters the sizer and passes out into its proper chute. The entire interior of the sizer is protected from wear by soft rubber as it has been found that rubber is the only material that will withstand the abrasion of moving granular ore pulp.

When the sizer is used in connection with the Sutton, Steele & Steele dry concentrating table, it is usual to make ten products when treating an ore that needs to be crushed to 18 or 20 mesh in order to free the different mineral particles; the sizes taken out are on 24 mesh, 24 to 30, 30 to 36, 36 to 48, 48 to 68, 68 to 97, 97 to 129, 129 to 140, 140 to 173 and through 173 mesh.

THE EFFICIENCY OF THE VIBROMOTOR ORE SIZER

On a recent test run made with a No. 3½ sizer on a zinc ore that assayed approximately 27 per cent. zinc, 1½ per cent. copper and 3 per cent. iron with a silicious and garnetiferous gangue, with the sizer arranged as a single unit, and so as to deliver ten products ranging from on 24 mesh to through 173 mesh, the machine gave a capacity of 54.86 tons per 24 hours and careful hand sizing showed the following results; one pound of each of the products being taken:

Size Product.	Screen Used.	Amount Through.
On 24 mesh.....	30 mesh	0.035 oz.
24-30 mesh.....	36 mesh	0.035 oz.
30-36 mesh.....	48 mesh	0.018 oz.
36-48 mesh.....	68 mesh	1r.
48-68 mesh.....	97 mesh	1r.
68-97 mesh.....	129 mesh	none
97-129 mesh.....	140 mesh	0.124 oz.
129-140 mesh.....	173 mesh	0.75 oz.

In the capacity and efficiency test made on a vibromotor sizer at Tiro General mill at Charcas, San Luis Potosi, Mexico,

during April, 1908, the vibromotor was arranged in two duplicate sections with separate feed to each of the sections which contained a series of screens with openings of 1/26 in., 1/34 in., 1/46 in., 1/60 in. and 1/80 in., and called for convenience 26-, 34-, 46- and 60-mesh screens.

The upper section was running at a capacity of 20.2 metric tons in 24 hours and the lower section at the rate of 42.7 metric tons per 24 hours; the efficiency tests were made on samples of each product while running at this rate. The ore that was fed to the vibromotor had previously passed a 16-mesh screen.

RESULTS OF TEST OF VIBROMOTOR SIZERS AT THE TIRO GENERAL MILL.

PRODUCT ON 26-MESH SCREEN.

	Upper Section.	Lower Section.

Through 80-mesh hand screen.....	10 grams	5 grams

The test was not carried farther on account of not having hand screens of finer mesh openings. The cloth on the hand screens used was in each case exactly the same as that used in the vibromotor.

It was noted that the largest portion of the product that went through the hand screen, but that went over the same screen in the vibromotor, was made up of elongated pieces of ore which had more time and opportunity to get on end and

so pass through the hand screens, than the screens in the vibromotor.

The following extract from a letter received by me on the subject explains the difference in capacity of the two halves of the sizer:—

"Regarding their efficiency, I give the following tests made by Mr. Emerson: From one section of the screen, which was taking a feed of 42½ tons per 24 hours, an average efficiency of 97¼ per cent. was obtained and from the other section, which was taking a feed of 20 tons per 24 hours, 97½ per cent. efficiency was obtained. In explanation of the difference in feed will say that the feed spouts on account of their location were not delivering equal amounts. Another test made on a feed, which figured 93 tons per 24 hours for the whole screen showed on the oversize an efficiency of 97 per cent. In figuring these efficiencies the next screen below the one being tested was used, which system is the fairest test I believe. Using the same screen, the efficiencies averaged 86¼ and 85½ per cent. respectively."

The Sutton, Steele & Steele vibromotor ore sizer is manufactured exclusively for Sutton, Steele & Steele, of Dallas, Texas, by the Allis-Chalmers Company, and is fully protected by United States and foreign patents.

Fast Driving on the Rand

The record on the Rand, South Africa, for driving with two machines made at the Van Dyk Proprietary mine, where an advance of 226 ft. was made in 26 days and nights, has been broken, and even the record speed for driving made at the Simmer Deep mine in April, where three machines were used, has been surpassed for at the Van Dyk Proprietary mine a drift has been advanced in 62 shifts, 9½ hours long, 323 feet.

THE VAN DYK RECORD

One white man and five Kafirs worked each shift, using two 3¼-in. Ingersoll-Sergeant drills. One round was drilled and blasted each shift. The following were footages for each measurement period (Sundays, of course, being excluded): Oct. 26-31, 12 shifts, 55 ft.; Nov. 2-6, 10 shifts, 50.5 ft.; Nov. 7 and 9-13, 12 shifts, 66.5 ft.; Nov. 14 and 16-20, 12 shifts, 68 ft.; Nov. 21 and 23, 28 and 30, 16 shifts, 83 ft.; total, 62 shifts, 323 ft. The average number of holes drilled per round was 12; the average advance per round was 5.209 ft.; the average number of pounds of gelatin used per foot was 8.513.

No bonus of any description was attached to the work either for white men or Kafirs, the Kafir being paid 1s. 7d. per

shift. No special conditions were used to aid the work, and no endeavor was made to secure specially long rounds, as ordinary length steel was used. This performance is certainly remarkable.

COMPARISON WITH THE SIMMER DEEP PERFORMANCE

It is interesting to contrast the details of this work with the figures for the Simmer Deep achievement. At that mine a drift was advanced 294 ft. in 61 consecutive shifts of 10 hours each. The size of the drive was 5x7 ft. One white man and six Chinese were employed on each shift, and they operated three Ingersoll-Sergeant drills on a bar. One round was drilled per shift, and the average footage per round was 4.82. The number of feet broken per case of gelatin consumed was 4.52; in other words, 11.06 lb. of gelatin were used per foot. Of the 61 rounds drilled, 59 had 14 holes each and two had 12 holes each. The air pressure at surface was 80 lb. per sq.in. It is interesting to note that special measures were taken to cool the drift after blasting and to eliminate dust. A water-pipe was connected with the air-pipe, so that the drive could be cooled, and the broken rock wetted without loss of time. After blasting the cut holes, water was forced by the air into the face, so that the contractor on returning to blast the round found the drive quite cool and free from dust.

Both these performances reflect the greatest credit not only on the miners, but also on the management and the Ingersoll-Sergeant drill. It should be taken into account that only two machines were employed at the Van Dyk, as against three in the Simmer Deep, and that the shifts worked at the former mine were half an hour shorter than those worked in the Simmer Deep.

FAST DRIVING AT THE VOGELSTRAUIS CONSOLIDATED DEEP

At the Vogelstruis Deep during November, 1908, a drift was driven with two machines 272 ft. This was done by six white men and six Kafirs (both shifts). The drift was 6 ft. 6 in. in the clear above rails by 3 ft. 6 in. and 4 ft. 6 in. wide in the clear. This also is a notable performance, but it was surpassed in December when the same drift with two machines on a bar was advanced by six white men and six Kafirs 305 ft. in 31 days. Twelve holes were drilled to the round. The drift is at a depth of 3000 feet.

Rhodesia presents a striking contrast to the big gold mines of its neighbor, the Transvaal. It is a country of small mines. Analysis of a recent monthly return show that 33 per cent. of the gold reported came from mills of five stamps or less; 52 per cent. from mines having from 5 to 10 stamps, and only 15 per cent. from mines having more than 10 stamps each.

*Abstracted from *South African Mining Journal*, Dec. 2, 1908, and Jan. 9, 1909.

Oklahoma's New Zinc-Lead District

SPECIAL CORRESPONDENCE

In September, 1907, the New State mine made the first production from the Miami mining camp in Oklahoma. Ore had been found in drilling southwest of the Quapaw mines and, following a drilling campaign, the Miami mining camp was a reality. The new camp is located three miles due north of Miami, Okla., and four miles southwest of Quapaw in the northeast corner of the State. The country is flat prairie land with a slight slope toward Tar creek, two miles to the east.

CHARACTERISTICS OF THE OREBODY

The ore consists of zinc and lead, and is found at a depth of 100 to 125 ft.; a face of from 16 to 30 ft. has been developed. Some timbering is required, but the roof is good and machine drills can be used.

The formation in the Miami mines is, so far, unlike that of any other camp. Under about 30 ft. of top soil and clay is found about 5 ft. of loose river gravel, and under the gravel 30 to 35 ft. of Cherokee shale. Below the shale is about 20 ft. of black, oily limestone and flint. Below this cap rock the orebody is found, impregnated with bitumen or crude oil, in flint and limestone in old solution-channels; the orebody will average 10 to 30 per cent. mineral in the proportion of six parts zinc to one of lead. Fine-grained iron pyrites is scattered throughout the ore. The zinc concentrates assay about 52 per cent. zinc and 7 per cent. iron, and bring about \$15 under base price for 60 per cent. zinc. The lead is of good grade and brings nearly base price.

The water problem was a hard one at the outset. Owing to the fact that it gave off hydrogen sulphide, it was feared that it had artesian head and would remain at about the same level. On the contrary, however, owing to the open nature of the ground, the first mine had to drain all the surrounding country; but with several mines pumping, the water supply was soon no more than sufficient for use.

There are now eight mills in operation, four mills contracted for and several shafts being sunk on drill holes. One square mile of territory has already been proved and 12 to 15 drills are at work in the camp thus extending its limits every day. The New State mine, with a mill that could not handle over 75 tons of ore per day, is the pioneer in the field, and is turning out 5 to 10 tons of concentrates per shift. The Tom Lawson, King Jack, Lucky Strike and Index are new modern mills of large capacity and are all producing. The Emma Gordon is a modern plant of 400 tons capacity. This company has 52 drill holes and five shafts in ore, and is operating on a 200-acre lease. It pays 1½ per cent. royalty.

Just south of the Emma Gordon is the Old Chief operated by Weis & Co. West of the Old Chief is the Buckeye of 200 tons capacity. The Muskogee, Golden Hen, Miami-Yankee and Dan Isley companies are erecting mills, and several companies are sinking shafts. J. W. Barnes & Co. have struck a run on the 10 acres west of the Emma Gordon from the 142 to the 165-ft. level. This is deeper than at any other mine, and the ore runs about 20 per cent. It concentrates, however, to about 57 per cent., which is high-grade ore and augurs well for the deeper runs.

CONCENTRATION DIFFICULTIES

Owing to the nature of the ore, the local concentration methods are not yet well adapted to handle the Miami product. The bitumen balls up in the jig beds and they require frequent cleaning. The fines float off in the oily water and are not saved by the tables as they should be. The richness of the ore is such that a great loss is entailed in handling too large a quantity and the tailings will, in every instance, have to be treated again. The iron in the concentrates is so great that roasting and magnetic separating will eventually have to be resorted to in order to raise the grade of the ore. One company is already reported to be planning to install roasters.

The camp is on Indian lands and is not owned in fee by the operating companies. The Miami Royalty Company and others have first leases on most of the land and pay about 5 per cent. royalty, subleasing to the different companies at the high royalty of 25 to 35 per cent.

PRODUCTION OF THE NEW FIELD

The result of the first year's work in the Miami field was a production of 6,202,390 lb. of zinc valued at \$75,606 and 1,007,720 lb. of lead valued at \$30,093; total, \$105,701. The average price of zinc ore was \$24.38, and of lead, \$59.73. This record was made by an average of three mills, which were shut down from Nov. 1, 1907, to April 15, 1908, operating only five and one-half months of the year and with ore prices at the lowest level for several years.

The second year should see an average of at least 12 mills running full time and with better ore prices Miami should rank among the first six camps in the district, surpassed only by Joplin, Webb City-Carterville, Galena, Alba-Neck City and Duenweg; and with a production reaching the half-million-dollar mark. The ore is a revelation to one accustomed to sheet-ground mining.

The royalties are too high and will have to be reduced; other companies will follow the example of the Miami-Yankee and purchase a reduction of royalty, if it is not granted. The methods of concentration will be changed and improved as experience is gained in the field. The grade of the concentrates will be raised

by removing some of the iron and bitumen.

Some of the companies are over-capitalized, and as their mills have been producing only about one-half of the claims they made and that with a value per ton of less than two-thirds of what they figured, the result has been that they have been unable to pay their guaranteed dividends. One cannot help seeing a great future for the youngest camp of the district, and with improved concentration, reduced royalties, moderate capitalization and wise management, the mines of Miami should be dividend payers.

Auriferous Alluvials of the Upper Amazon Valley *

By SIR W. MARTIN CONWAY

During my explorations in the perpetual-snow region of the Cordillera Real in 1898 and 1900, I came across points where veins of gold-bearing quartz were exposed, but always inaccessible so far as any possible working is concerned. A conclusion that at a very high level on the eastern face of the snowy range a considerable body of gold ore exists was confirmed when I discovered that all four of the principal tributaries of the Upper Beni, or Kaka, river bring down gold in their gravels. These rivers, in order from south to north, are the Corico, Challana, Tipuani and Mapiri, on all of which natives wash gold out of the gravels; and set up riffles before the rainy season. The Tipuani rises at the crest of the Cordillera, and near its headwaters is a place called Yani. In the mountain side strong veins of gold-bearing quartz have long been known; and since the days of Pizarro it has been possible to pan gold all the way down the river. The richness of Tipuani gravels has been described by Weddell.

What is true of the tributaries of the Upper Beni is so of those of the Upper Inambari. Twenty-one rivers flowing into the Inambari bring down gold, and 15 are regularly frequented by Indian gold washers.

We have thus proof that the eastern slope of the Cordillera Real for over 200 miles yields gold, in all its river gravels, which must originally have come from the heart of the range itself.

From these upper tributaries of the Beni and Inambari the Incas doubtless obtained their vast supply of the precious metal. Then why has it never been worked on a large scale, with the assistance of modern methods of extraction?

The determining obstacle, in my

*From a paper read before the Royal Society of Arts, and published in the *London Mining Journal*.

opinion, is the rainy season. Tropical downpours of enormous volume—sudden, violent discharges—continue day after day, resulting in sudden and overwhelming floods, river after river; enormous landslips and mud avalanches scour the gullies—machinery in such a region is impossible. All attempts to set up hydraulic apparatus have failed, even lower down, to win gold from these rich Andes torrents. No one has succeeded since the Incas, who employed forced labor and got their gold by hand-panning.

ENRICHING PROCESSES

For countless ages this transportation of gold from aloft has continued. The Andes have been piling their own débris about their feet since the Corderillas first rose out of the level plain. The foot hills of the Bolivian part of the Corderilla were discovered by Dr. Evans to contain gold in their slates and conglomerates. He observed on the Kaka river that those gravels were richest in gold which were found just below a gorge in the foot hills. At such points the gold has undergone a second concentration—sometimes, perhaps, even a third. It follows that the best sites for gold washing are not necessarily those nearest the source of first supply, but may be found considerably lower down. This gold almost invariably consists of flattened particles, like fat little grains of gold which have undergone pressure.

I now come to the important discovery to which my own observations and conclusions contributed somewhat. When I became thoroughly acquainted with the geography and gold-carrying properties of the tributaries of the Kaka, or Upper Beni, river, and realized that this gold could not be won, mainly because of the overwhelming rush of waters; and when I learned that the four great tributaries after uniting near a place called Guanay enter a gorge which is not wide enough for any considerable deposit of gravels to take place along its banks; it occurred to me that if anyone would descend this gorge, as can easily be done on a raft, he would be likely to find somewhere below the gorge, wherever the steep banks first receded, some extensive deposit of gravel rich in gold.

INCAHUARI GROUND

In 1898 Dr. George Bridgman, then American minister to Bolivia, with whom I talked the matter over, procured an expert American gold prospector, who went down and passing through the long gorge below Guanay came out into an old lake basin, filled to the brim with gravel in the course of ages. He landed on the bank, and proceeded to wash a pan of gravel. To his astonishment it yielded gold at the rate of 17s. 6d. (\$4.25) per cu.yd. He had never seen the like in all the years of his wanderings, and he

hastened back to La Paz in a state of excitement, of which I was witness when I chanced to arrive a few days after he had come in.

That was how gold came to be discovered on the lower and quieter reaches of the Kaka (Beni) river. No one had ever thought of looking for it so far down; the possibility of a second concentration had not occurred to them.

Since then many expeditions have gone down, and the ground has been examined almost yard by yard over the areas that are now in possession of different owners. The most important one, from a scientific standpoint, was that of Dr. John Evans, formerly mining adviser to the Government of Mysore, and now geologist to the Imperial Institute. At that time difficulty of access was the great impediment. Since then a new good mule road has been made from La Paz to the kinder waters of the Corcoico over which machinery can be, and has been, carried. The remainder of the way has to be negotiated by raft, but I understand that the government intends to carry the road itself down to the Incahuari dredging ground, as the lake basin mentioned is called, during the coming year.

Italian Asphalt

One chapter of "L'Industrie Minière et Métallurgique en Italie," by P. Nicou, published in a recent *Bulletin de la Société de l'Industrie Minérale*, treats of the asphalt deposits of Italy, with particular reference to those of Sicily.

Speaking first of the leading deposit on the mainland, situated at Tocco and other villages in the Abruzzes district on the east side of the peninsula, it is stated that the asphalt of this locality was known and utilized by the Romans. The principal operations are now conducted by the Neuchatel Asphalte Company, Ltd. The asphalt impregnates limestone and is also found in the form of veins traversing the rocks. The impregnated rock is treated in 10 to 20-retort furnaces at the works near San Valentino. The crude rock carries 10 to 16 per cent. bitumen, but only about 5 or 6 per cent. is recovered, since nearly two-thirds of the rock is consumed as fuel under the retorts. The average annual production has been about 500 tons of finished asphalt, derived from around 10,000 tons of rock. A small quantity of the richest crude rock is exported to Hamburg, at which place it is worth about 28 francs per ton. Other parts of the deposit, in which the impregnation is more regular, are also operated. Part of the output is sold in its crude condition to the State, part is pulverized to make asphalt blocks, and part is made into mastic. The annual output of this class of rock has been 25,000 tons. Another less productive mine on the mainland is

the Filetino, at Amaseno, in the province of Rome.

By far the most productive locality is that of Regusa, in Sicily, the annual production of which has exceeded 100,000 tons. Certain parts of a very pure, fossiliferous, Miocene limestone are found to be regularly impregnated with bitumen, forming an asphaltic rock of the first quality. There are two such horizons, the first, the lower one, having a thickness of 5 m. containing thin beds of only slightly bituminous limestone, and the second, 15 to 25 m. above the first, having a thickness of 5 to 20 m. Elsewhere, without any fixed relation to the stratified deposits, are found irregular masses of asphaltic rock.

Most of the working is done in open cuts, but in some of the thickest deposits underground methods, with either drifts or shafts, are employed. Explorations to the south of Regusa have yielded very variable results; immediately south of the town, a strong, rich horizon was found at one point at a depth of 50 m., while elsewhere borings have found a less bituminous, argillaceous rock. Good rock was found at Scicli, while at Modica the results of exploration were poor.

In addition to the exports of crude rock, which go mainly to Germany, England and the United States, part of the output is manufactured into mastic locally. The Società Sicula per l'Esplorazione dell'Asfalto and the Worwöhle-Rock Asphalte Company, Ltd., both have plants at Regusa, the former using partly Trinidad asphalt and partly bitumen extracted from the less regular local rock.

Determination of Antimony

L. A. Youtz (*Journ. Am. Chem. Soc.*, XXX, pp. 975-979), has investigated the purity and volatility of precipitated antimony sulphide. Precipitation as the sulphide is one of the most used methods for the determination of antimony and, while accurate results are often obtained, this desired end many times is the result of a series of compensating errors in the work.

For preliminary investigation two portions of antimony trichloride of about 1.5 grams each were dissolved in 250 c.c. of water and 30 c.c. of concentrated hydrochloric acid, the antimony precipitated with hydrogen-sulphide gas, the solution diluted to 500 or 600 c.c., warmed nearly to boiling and saturated with the gas. The sulphides were thoroughly washed with water saturated with hydrogen sulphide until at the most only a trace of chloride was discernible in 10 c.c. of the washings.

The precipitate was then tested for chlorides by fusing with sodium carbonate in a porcelain crucible, the fusion taken up in water, acidified with sulphuric acid, the sulphide filtered off and the filtrate tested for chlorides after expelling the

hydrogen sulphide. Blank tests were run in every case. It was found that notable quantities of chlorides were present in the sulphides even when working with smaller amounts of the sulphides than in the two first tests.

To determine if tartaric acid was effectual in reducing the amount of adherent chlorides, 5 grams of the acid were added to the solution before precipitation of the sulphides, but the results in all cases showed that tartaric acid was ineffectual. In another trial the antimony sulphide was dissolved in ammonium sulphide and reprecipitated with acetic acid, but still appreciable amounts of chlorides were present. The enumerated tests are only a few of the many tried, which all yielded like results, chlorides being practically the only impurity considered.

The tests on the purity of the sulphide incidentally brought about an investigation of the volatility of the precipitated sulphide. Uniformly in these tests the precipitates were heated in an atmosphere of carbon dioxide at a temperature of approximately 250 deg. C. after drying to constant weight at usually 105 to 100 deg. C. in air. The precipitated sulphides were collected and washed in Gooch crucibles with asbestos filters, dried and placed within a small beaker covered with a watch glass and the air expelled with carbon dioxide. The beaker and contained crucible were heated in an asbestos oven and the temperature noted by means of a thermometer inserted through the perforated watch glass.

The many tests that were made proved conclusively that when chlorides are present in the precipitate, constant weight is impossible to attain. The loss in weight varies with prolongation of the heating and was due wholly to the presence of chlorides in the precipitated antimony sulphide.

Quantitative results are, however, attainable especially if the heating be not longer than 30 min., in which cases results, accurate enough for practical purposes, may be obtained. This is not so surprising if the fact is considered that the chlorides are present as SbOCl and $\text{Sb}_2\text{O}_3\text{Cl}_2$, and that the molecular weights of these salts and Sb_2S_3 are so nearly the same that several per cent. of either salt as an impurity would give practically the same weight as if present as the sulphide.

The total silver coined at the United States mint for the Philippine islands up to the end of 1907 included 37,302,358 pesos; 9,441,143 pieces of 50 centavos, or half pesos; 12,413,419 of 20 centavos, and 17,788,338 of 10 centavos. This coinage required 32,421,872 oz. fine silver, of which 26,568,707 oz. were new bullion, and 5,853,165 oz. were obtained from old Philippine and Spanish coins melted. Minor coinage included 9,999,884 five-centavo pieces, of nickel; 37,845,234 centavos and 17,752,884 half centavos, of bronze.

Great Falls of the Missouri

The accompanying illustration of the Great Falls of the Missouri is from a photograph in the program of the 22d annual meeting of the Montana Society of Engineers, held at Great Falls. These falls are situated about 12 miles below the city of Great Falls and development work for the utilization of the power which they afford is now in progress. The natural fall is 72 ft. The work will consist of a dam 700 ft. long and 26 ft. high, placed a short distance above the crest of the falls. The water will be carried from the dam to the power house by a penstock 22 ft. in diameter. The tail race will be excavated below the island or point near the foot of the falls and thus utilize whatever fall there may be in the river between the

lines. Over 36 hoisting engines are now operating in the camp and the various workings vary from 400 ft., the deepest shaft, up to 250 ft., to which depth the greatest number of shafts are now sunk.

Mining engineers who have inspected the camp during the past few months report that the formation is favorable for the class of ore which is now being developed, and that the veins so far encountered bear indications of permanency. The past few months have brought decided relief to the various leasing companies operating in the camp. Mills are being established—some of them are already running—which are capable of treating the ores which are offered with a good degree of extraction. The milling era has arrived in the camp, and from now on it should improve from a mining standpoint as well as in a financial way.

GREAT FALLS OF THE MISSOURI, MONTANA

foot of the falls and the mouth of the tail race. The entire installation will result in a working head of 110 ft. The water wheels will be of the turbine type. The generators will be three-phase, 60-cycle, 60,000 to 100,000 volts, the exact voltage not having been determined upon.

Impressions of Rawhide

SPECIAL CORRESPONDENCE

To the visitor to Rawhide, Nev., today, the most important point is the evidence that development work is going forward through the heart of the camp. Beginning on the property of the Rawhide Mining Company at the north center and extending for over a mile to the Rawhide Consolidated on the south, and from the Rawhide Queen estate on the east to the Rawhide Coalition on the west, there is presented mining activity along legitimate

The camp has had many difficulties to face. It was started during a serious financial panic; it received its first impetus from an unwarranted real-estate boom which soon collapsed, to be followed very shortly by the failure of both banking institutions in the camp, thereby entailing a serious loss to the operators; early in the fall the entire business section was destroyed by fire. With all these drawbacks, it required more than faith to keep the men at the camp and at work.

The value and permanency of Rawhide depend on the large veins of medium-grade ore encountered in the various workings. From time to time high-grade bodies of ore may be struck in the camp, but the main dependence of the operators there is their ability to develop in large quantities the lower grade ore with the facilities for rapid and economical treatment at hand.

Burning Wood under Boilers*

By E. G. TILDEN†

Our boilers, two of them, about 60 in. by 16 ft., of the ordinary tubular type, were equipped with rather old-fashioned fronts, as indicated in Fig. 1. The grate was so near the shell of the boiler that in the middle of the furnace there was room for only one layer of logs, the fuel being 4-ft. cordwood. This was the seat of most of the trouble, for being thinnest at that point, the fire burned through quickly, requiring constant attention to keep the steam up.

It was finally decided to remodel the furnaces as shown in Figs. 2 and 3. The grates and bearers were removed, the grate level dropped to the floor line and only two 6-in. bars were used, these be-

The draft was governed or regulated mechanically by working the damper in the base of the stack, the ashpit opening being left full. These alterations reduced the fuel consumption fully one-quarter, besides saving the fireman a lot of work and bother.

Regarding the claimed advantage of a deep fire-box for burning wood, is it not a fact that the flow of unused cold air through the furnace and setting of steam boilers is the source of a great deal of fuel waste? Regulating the steam pressure by manipulating the ashpit doors is, I believe, conducive to this same overplus, or useless air trouble. Closing the ashpit doors will, of course, deaden the fire, but it also introduces another set of conditions that tend to cool off the boiler; that is, closing the ashpit doors increases the draft in the furnace, thereby increasing the flow of air through the leaky places in the setting above the fire; and as all this air leakage goes in at the

Precious Metals Used in the Arts

According to the estimate of the director of the United States Mint, the quantities of gold and silver used in the arts in the United States in 1907 was as follows:

	Gold Value.	Silver Fine Oz.
Domestic billion.....	\$15,546,921	17,431,691
Foreign material.....	14,502,571	4,628,308
U. S. coin.....	3,500,000	77,344
Old material.....	7,177,575	2,232,641
Total.....	\$40,727,070	24,369,784
Total, 1906.....	39,126,763	21,853,264

The quantity of coin used is entirely an estimate. Deducting this, the Government mints and assay offices furnished 91.7 per cent. of the gold bars and 20.1 per cent. of the silver bars taken for use in the arts; private refineries supplying 8.3 and 79.9 per cent., respectively.

FIG. 1

FIG. 2

FIG. 3

ing placed in the middle as shown in Fig. 2.

With the firebrick filling we made no attempt to smooth up the rough corners due to battering the courses of brick, but depended on the steep pitch of the furnace walls to roll the logs down to the center as they burned away. The side-wall angle was about 45 deg. and in service proved to be all that could be desired.

The original length of furnace, 4 ft. 6 in., was retained, but the two grate bars were cut off to about 3 ft. 10 in., to stop useless cold air from flowing through the furnace.

The front of the new furnaces, that part directly under the fire doors, was firebrick lined, the old ashpit doors being sealed up entirely, the narrow trench under the grates serving for the ashpit and an air inlet.

temperature of the boiler room, and goes out the stack at or above the temperature of the steam in the boiler, a lot of coal is burned just to moderate the weather.

To those who think their boiler settings are practically tight, I suggest the following easy way to find out if they are: Make a "smoky" fire, say of soft coal and before the volatile matter has had a chance to get away, close the overhead damper tight, leaving the ashpit doors open. Black smoke will roll out through every crack and crevice in the setting. Now, reverse these conditions, open the stack damper and close the ashpit doors, and cold air will roll in through the same cracks and crevices. Ordinarily the conditions under which steam boilers are operated are such that it is impracticable to keep the settings air-tight, for which reason overbalancing the pressure in and outside of the furnace should be avoided as much as possible.

This estimate does not take into account the old gold and silver melted down privately and used. It is probable that most of the gold remelted is passed through the assay offices in order to secure the government certificate as to its fineness; but a considerable quantity of silver may be used in this way without passing through either government or private refineries.

The quantity of the precious metals thus estimated as used in the arts was equal to 45 per cent. of the gold mined in the United States in 1907, and 43 per cent. of the silver. No estimate for 1908 has yet been made.

On the basis of such returns as could be obtained from foreign countries, the total quantity of the precious metals used in the arts in 1907, is estimated at \$135,046,500 in gold, and 92,568,300 oz. of fine silver. This is 32.9 per cent. of the gold and 50 per cent. of the silver mined in the world in that year.

†Downers Grove, Ill.

The Blanc Turbo-Classifier

The *Comptes Rendus* of a recent meeting of the Société de l'Industrie Minérale describes the construction and operation of a novel classifier designed by F. Blanc, and gives data on its capacity, water consumption and thoroughness of separation. In a general way the apparatus closely resembles a centrifugal pump, in that it both sucks in its own feed and discharges at an elevation, if desired. This classifier will separate two minerals whose specific gravities differ but little; the inventor states that it will make a clean separation of cerussite from a lead-zinc ore containing cerussite and calamine.

The moving part of the machine is a narrow drum, which is composed of two disks, bolted face to face. The disk *A* is

flat piece *R* made of hard steel; this is to withstand the wear, which is severest at this point.

In operation it is found that with fixed conditions, only those particles with a certain specific gravity or higher will be caught by the points *P*; the particles thus retarded pass through the holes *E* into the chamber *D*, whence they are delivered through the discharge pipe *U*. The cock *Y* and the jar *X* are for the purpose of taking samples of the concentrate. The lighter particles, constituting the tailings, are ejected from the ends of the channels into the annular chamber *V*, whence they pass out through the pipe *T*, or through the cock *Z* provided for taking samples of the tailings.

The narrowest point of the channel is about 10 mm. square, which limits the size of ore particles to this dimension, but

cerussite and calamine in a silicious limestone gangue, brought from Djebel Felten, Algeria, was crushed to pass a 6-mm. screen. It assayed 28.80 per cent. lead and 14.20 per cent. zinc. It was desired to make a concentrate carrying 50 per cent. lead. The opening at *P* was 11 mm., the average speed was 1200 r.p.m., with a pressure on the gage of over 3 m. of water.

Speed. R.P.M.	Pressure. Meters of Water.	Lead in Concentrate. Per Cent.
700	0.9	40
950	1	47
1200	1.5	47½
1200	3	55
1200	4.5	57½
1200	6.5	58
1200	8	67½
1200	9.5	68

The current of water passing through the machine will carry and classify about one-fifth of its volume of ore. At a speed of 1200 r.p.m., and with a discharge pressure equal to 5 m. of water, the machine will treat 5 cu.m. of ore, carried along by 25 cu.m. of water per hour.

The pressure created in the discharge pipe by the classifier can be utilized either for lifting the tailings up to settling tanks for further treatment, or to recover the water, or for carrying the tailings to a distance for dumping. In either case no elevator is required, and the pressure, once fixed, needs no further regulation at the cock *IV*.

Radium in England

In order to encourage research work with radium a new institute is being formed to be called the Royal British Radium Institute. The council contains distinguished names in the medical and chemical world, such as Sir William Ramsay, Sir Frederick Treves and Prof. J. J. Thomson. The use of radium for medical purposes is but little understood, and there are differences of opinion among medical men, judging by correspondence that has appeared recently in *The Times*, as to its healing properties. An institute endowed with funds to enable exhaustive experimental work to be carried out with this very expensive and mysterious substance, cannot fail to secure knowledge of great benefit to humanity.

The principal source of radium is the mineral pitchblende, or oxide of uranium, which is found principally in Bohemia and Cornwall. It is noticeable that the publication of the formation of the new Radium Institute has produced paragraphs in the newspapers calling attention to the supplies of pitchblende in Cornwall that await exploitation. The company promoter may be trusted to make the most of a magic word like radium, and it is not unlikely that the public will be invited to subscribe for the opening of abandoned mines, where pitchblende has been known to occur, without the commercial possibilities having been closely examined. Radium mines should be treated with caution.

FIG. 1.

FIG. 2.

FIG. 3.

THE BLANC TURBO-CLASSIFIER

a plain flat plate, rigidly attached to the driving shaft. The plate *B*, Fig. 2, has on one side a number of curved radial channels, enlarging outwardly. Through these flows the current of water carrying the ore in suspension. Toward the outer end of each channel, and on the side opposite to the direction in which the disk is to revolve, is a little pointed piece *P*, made of the hardest steel, and held in position by the screw *I*. The distance to which this point extends out into the channel can be adjusted by loosening and retightening this screw. Just in front of the pieces *P* are the holes *E* which extend through the plate. The front edge of the hole *E* is protected by the inseting of the

for good operation the ore should have been passed through a screen with 5-mm. holes.

In the operation of the machine three adjustments are possible: Speed of rotation; rapidity of discharge; and the width of the opening at *P*. The speed depends upon the type of driving power, and can be varied at will. The rate of discharge is regulated by the cock *N* and the pressure gage *M*; as the cock is closed the pressure recorded by the gage increases. The opening at *P* can be regulated by dismounting the disk and adjusting each of the points separately to the desired width.

The following results of a test on the machine are given. The ore, a mixture of

The Balaklala Consolidated Copper Company

A Comprehensive Statement of General Conditions and Summaries
of the Mine, Smelter and the Aerial Tramway Operations During 1908

ABSTRACT OF OFFICIAL REPORT

The first annual report of the First National Copper Company gives a full and comprehensive statement of the operations of the Balaklala Consolidated Copper Company (the operating company) at Coram, Shasta county, Cal., for the year ending Dec. 31, 1908. Thomas J. Barbour, president of the Balaklala company, in submitting the report, states that the mine was operated for 60 days, and the smelter 52 days during the year. Difficulties are gradually being overcome and blister copper is now being produced. Indications are that the ore developed will average about 2.7 per cent. copper, 0.025 oz. gold and 0.75 oz. silver per ton. Costs will be materially

MINING

R. N. Bishop, mine superintendent, reports that previous to October, 1908, there were five men employed in the mine, it being necessary to have sufficient men as a precaution against fires. These

men worked in the mine and did some development work on a new body of ore at the junction of the Weil tunnel and No. 2 south crosscut. This body proved to be high grade, but its limits have not been defined as yet. They also did some development work at the top of No. 2 upraise, endeavoring to find the eastern boundary of the ore.

On Oct. 1, a crew was put on at the mine and everything made ready to supply the smelter with about 300 tons of ore per day by Oct. 15. During the last three months of the year 18,751 tons of ore were mined. Of this, 17,450 tons were delivered to the smelter. Although oper-

SMELTER OF BALAKLALA CONSOLIDATED COPPER COMPANY, CORAM, CAL.

reduced when the full capacity of 1250 tons per day is reached. Attention is called to the fact that operations were only conducted for part of two months and one full month, whereas expenses are figured for the full three months.

The balance sheet shows total assets of \$10,822,034, in which the mines and property are valued at \$8,688,777. Liabilities are as follows: Capital stock, \$10,000,000; first mortgage bonds, \$750,000; accounts payable and pay-rolls, \$72,034; total, \$10,822,034. The following entries under construction and property are of interest:

Ore mined, 18,751 tons.		

ations have not been carried on long enough to arrive at what the average cost of mining will be, it is evident that it will be about \$2 per ton.

In the mine ore is being blocked out and levels run every 25 ft., it being the intention, after the ore is blocked out to the roof, to start at the furthest wall and take a vertical slice off the pillars and retreat from the wall, leaving the roof unsupported. This method of mining will permit the extraction of all the ore without using any timbers and should permit of cheaper mining than if timbering were resorted to.

The Windy Camp deposit has been opened up, and it is now in shape to deliver as much ore as the Weil level deposit. Development work has been started at the eastern end of the Weil deposit.

Experiments on the aerial tramway have demonstrated that with the present controller it is dangerous to operate at a greater speed than 450 ft. per minute, and the builders have been asked to furnish an additional controller so that a speed of 500

ft. per minute may be attained without risk. Also there is shown a plan and sections of the mine, indicating the size and location of the orebodies developed.

GENERAL CONDITIONS

R. T. White, manager, states that after

rectors held in New York in March, 1906, but because of many unavoidable delays and the scarcity and poor quality of labor for constructing the necessary railroad sidings, it was not until Nov. 4 that the first carload of material for the founda-

LONGITUDINAL SECTION AND PROJECTION THROUGH A-B; BALAKLALA CONSOLIDATED COPPER COMPANY

ft. per minute may be attained without risk. At this speed the tramway will deliver 75 tons of ore per hour.

Summaries of the mine and tramway operations are given in accompanying

a long period of development and construction work, the property has now been placed on an operating basis. The type of smelter to be constructed was decided upon at the meeting of the board of di-

rection was delivered at the smelter site. The work was almost completed by the middle of October, 1907, when on account of the lack of funds all work was suspended. On April 1, 1908, the company's finances hav-

ing been readjusted, a small force was put at work again, and continued during the succeeding months, finishing the various incomplected items and adding others not originally planned. The company had entered into a contract for the sale of its matte for a period of 15 years, and, therefore, the original plant did not include converter equipment. Upon the resumption of work this year, however, the matte contract having been annulled, a converter plant was planned and has since been installed.

SMELTER EQUIPMENT

The smelter equipment consists essentially of the following: Four 18-in. diameter McDougall roasting furnaces; three 55x240-in. water-jacketed blast furnaces, and one 17x92-ft. reverberatory furnace; 3 double casting machines for casting matte; 6 converter shells, 96 in. diameter by 150 in. long, 2 electrically operated converter stands; 1 sampling mill for custom silicious ores, capacity 25 tons per hour, 1 sampling mill for sulphide copper ores, capacity 10 tons per hour; storage bins of the following capacities: sulphide ore, 7000 tons; silicious ore, 6500; lime rock, 3000; coke, 4500; matte, 800.

The power plant has the following equipment: three 256-h.p. Stirling, oil-fired boilers; two 300-h.p. Stirling waste heat boilers connected to the reverberatory furnace; three 14 and 30x36-in. 450-h.p. tandem compound condensing engines, direct connected to: three pressure blowers having a capacity of 300 cu.ft. of free air per revolution; one cross-compound converter blowing engine, having a capacity of 11,000 cu.ft. of free air per min.; one 150-kw. A. C. generator operated by a direct-connected 225-h.p. A. C. motor; all necessary pumps and auxiliaries.

ORE TREATMENT

The coke, lime rock and silicious ores are received at the plant on railroad cars; the sulphide copper ores are received from the company's mine by way of an aerial

NOTE.—Tramway operating is credited with 15c. per ton, the balance to accrued accounts.

tramway. At the discharge terminal of the tramway, the sulphide ore is screened, that smaller than ½ in. going to the fine, and the oversize to the coarse bins. The fine ore is first subjected to an oxidizing roast in the McDougall furnaces, and the resulting calcine, together with flue dust from the blast furnaces, is smelted to matte in the reverberatory furnaces. The coarse ore is smelted in the blast furnaces, together with silicious ore and lime rock, producing a low-grade matte, which is afterward concentrated, i.e., resmelted with more silicious ore and lime rock to a higher-grade matte. This high-grade matte, together with the matte from the reverberatory furnace, is poured direct into the converters, where it is oxidized and the shipping product containing 99 per cent. of copper is produced.

The ore is handled from the bins to the furnaces in scale charge cars drawn by electric locomotives, the slag is hauled from the furnaces to the dump by electric locomotives, and the matte is handled by electric traveling cranes. The entire plant is substantially constructed. The furnace units are all of large dimensions, and consequent capacity, and everything is arranged to handle material with machinery as much as possible, thereby eliminating labor to the lowest degree.

It is estimated that the plant when in full operation will treat about 1250 tons of copper sulphide ore per day. The first blast furnace was started on Oct. 21, and continued in operation until Nov. 4, when an accident to the aerial tramway caused the shipments of ore to be stopped and the furnace was, therefore, temporarily closed down. The tramway having been repaired, the furnace was started again on Nov. 23.

ORE TREATED

The ore treated during the three operating months is shown in the following table:

The converter department was started the latter part of December, since which time there was produced 58,140 lb. of blister copper. There remains on hand 5060 tons of low-grade matte that was made during October, November and December, before the converters were started. Operations thus far have not been of sufficient

extent to demonstrate what the final cost of ore treatment will be, except that the tendency is to confirm previous estimates of about \$2.50 per ton of ore reduced to matte, and about \$15 per ton of copper converted.

Details and summary of smelting operations are given in accompanying tables. A view of the smelter is also shown

broken by blasting and shoveled into ore cars by hand labor; all material goes to the mill for grinding and drying.

Since the schist contains more or less talc, clay and moisture, the large lumps are crushed in a breaker. From here it goes to a calciner, where it is thoroughly dried, and more or less disintegrated by the generation of steam within the schist.

A Georgia Graphite Deposit

An industry that is yielding fair profits to the operators is the mining of the graphitic schists that occur at Emerson, Carter county, Ga. The graphite is the amorphous variety and is disseminated in a schist in amounts varying from 5 to 15 per cent. The outcrop is on a high ridge, which has been cut by a small creek, leaving the deposit exposed to a depth of 200 ft. The graphitic schist is 100 to 200 ft. thick, and has been tested to a depth of 500 ft. below the present working face. The vein is practically vertical.

Mining was begun at the creek level, and is simply open quarrying. The exposed working face is more than 100 ft. high and increases in height as the work progresses toward the hill. The schist is

From the calciner it passes through a 20-mesh trommel. The fines go direct to the storage room, or car for shipment, as the case may be. The oversize is sent through rolls and burs and ground to 20 mesh.

The cost of mining, drying and grinding is low, as the product is sold f.o.b. cars at mine for \$1.25 to \$1.75 per ton, and yields a profit at this price. The schists containing only a low percentage of graphite yield a light-colored material, while the higher the carbon content the darker the finished product. The value depends largely upon the color.

The American Chemical Company and the Cherokee Chemical Company are working this deposit, and during the year 1903 the combined output was approximately 30,000 tons.

Chronology of Mining, February, 1909

Feb. 2—Explosion in slope No. 2 in Short Creek coal mine of Birmingham Coal and Iron Company killed 17 men.

Feb. 6—President Guggenheim, of Guggenheim Exploration Company, issued detailed report.

Feb. 8—Strike of men at Velardeña smelter, Mexico. Second explosion in Leiter mine at Zeigler, Ill., killed three men.

Feb. 10—First report of the Copper Producers' Association shows 144,130,045 lb. copper on hand Feb. 1. Stock of American Smelting and Refining Company transferred from unlisted to listed department of New York Stock Exchange.

Feb. 11—Marianna coal mine resumed operations.

Feb. 12—Three copper companies of Arizona, Copper Queen, Old Dominion and Detroit Copper, filed complaints against railroads for excess freight charges on coke.

Feb. 15—First steel made at Gary, Ind.

Feb. 16—Explosion in West Stanley coal mine, Durham, England, wrecked 700-ft. shaft and killed 120 men.

Feb. 17—Trinity copper mine shut down.

Feb. 19—U. S. Steel Corporation declared open market for steel products. Heavy cuts in prices of steel. Judge Hunt, United States Court of Montana, denied injunction to ranchers to stop dumping of tailings in creek by Butte companies.

Feb. 23—Break in price of copper.

Feb. 24—Annual meeting of A. I. M. E. opened at New Haven, Conn. Rolling mills at Gary, Ind., finished the first rails.

Feb. 25—Tennessee Copper Company and San Toy Mining Company annual reports both showed deficits. Possible fine in the Standard Oil rebating case reduced from \$29,000,000 to less than one million.

Feb. 26—Settlement of dispute between Calumet & Hecla and Osceola announced.

Daly-Judge Mining Company

The annual report of the Daly-Judge Mining Company for the year 1908 shows receipts from the sale of all classes of ore during the year of \$285,570, of which \$14,167 were for zinc middlings. The interest earned on the surplus invested in securities was \$6918, or 5.41 per cent. The surplus was increased by \$1,342. The total receipts were \$420,144, and the total expenditures \$288,147, leaving a balance on Dec. 31, 1908, of \$131,997.

Of the expenditures mine account absorbed \$142,718; milling, \$42,670; prospecting and dead work, \$56,125; sampling, assaying and hauling, \$14,822; construc-

tion, \$9427; and general expense, \$15,635.

Costs of ore extraction and concentration were reduced materially. The cost of mining was \$3.03 as compared with \$2.77 per ton for the year previous, and concentration 95c., reduced from 86c., the tonnage being less than during 1907.

The most important development work of the year was the advancement of the drain tunnel which parallels the Ontario-Daly fissure 1145 ft. Several crosscuts were driven to the vein three of which developed ore.

The plant at Park City for the treatment of zinc middlings was completed during the year. Its capacity is about 50 tons per day. The concentrating mill produces about 15 tons zinc middlings per day, and there are about 15,000 tons of the same product on hand.

The ore mined during the year amounted to 51,805 tons, of which 50,536 were milling ore and 1269 tons of shipping grade.

The Phosphate Land Question

SPECIAL CORRESPONDENCE

F. B. Weeks (connected with the Geological Survey from 1890 to 1908) has made a lengthy statement concerning the phosphate-land question to the house committee on public lands. Mr. Weeks has made special inquiries in Utah, Wyoming and Idaho. His oral testimony was largely directed to the extent of the phosphate deposits of the United States and tended to refute the claim that they are so limited in character as to warrant special treatment of them by the Government. Mr. Weeks said that no survey of the South Carolina deposits which would render possible any definite statement about them has ever been made. The discovery of cheaper deposits in Florida was the reason why the working of the South Carolina fields declined. The introduction of better transportation has rendered the deposits more available than ever before. In Arkansas there is an extensive phosphate field and probably one of the largest phosphate fields in the world is in northern Africa. Some deposits occur in France and some in Australia. Large apatite deposits are found in Canada. At Cokeville, Wyoming, Mr. Weeks found fields of commercial value. In reply to questions from Chairman Mondell he criticized sharply the assertions of the Government authorities regarding 100,000,000 tons as the supply of phosphate in the Wyoming field. As to the question of exports, Mr. Weeks said that if a reasonable freight rate could be secured from the beds to San Francisco the phosphate could be commercially shipped to Japan and Australia, but that at present rates there was no profit in the business. The material could not be put on

board the cars at Montpelier under \$2.50 per ton. The witness added that if the deposits were to continue to be entered and located under the mining laws the location as placers would be preferable.

THE PROPOSED LOCATION LAW

The Mondell bill as finally reported by the committee proposes two things—that the lode locator may take his claim, but without any extralateral rights beyond the perpendicular boundaries of his claim and that in passing upon the entries already made the Department of the Interior shall hold that either kind of location was valid at the time it was made if prior to any other location.

Chairman Mondell, on behalf of the committee on the public lands, has filed a report explanatory of the bill favorably acted upon by the committee defining the manner in which public lands containing deposits of phosphate and phosphate rock may be acquired. The report says that the necessity of the legislation became apparent some time before the introduction of the bill in May, 1908, by reason of the fact that there was much confusion among locators as to whether the lands containing phosphate deposits should be located under the placer- or lode-mining laws.

The fact that the Department of the Interior recognized as valid and patented phosphate lands under the lode laws naturally alarmed the placer locators, and in quite a number of instances the same parties located their land under both lode and placer locations so as to prevent possible claim jumping and complications. Many claims are thus held, the locators attempting to comply with both laws on the same tract of ground and uncertain under which law they ought to make application to enter.

The proposed legislation deals with two distinct problems: the question as to which of the mining laws best fits the conditions surrounding these deposits, and, what disposition should be made of the locations heretofore made.

The committee is of the opinion that inasmuch as there is grave doubt as to whether any lode locations should have been made upon these deposits, and in view of the fact that the extra-lateral right if recognized might be the basis of claims to very extensive areas of the deposits and lead to expensive litigation in support of these claims, the lode locator has no ground for complaint if his rights are limited to the deposits within the perpendicular boundaries of the lands claimed by him. According to the report there is little doubt as to the authority of Congress in this matter.

After describing the phosphate deposits at issue and estimating them at 4,300,000 acres, the committee points out that after the withdrawals were made the advisability of attempting to segregate phosphate-bearing lands from agricultural lands and to lease the phosphate lands was sug-

gested by various government officials. The suggestion of leasing the lands was based upon the statement that the phosphate deposits of the world at large and of the United States were more or less limited, and that the agricultural lands of the United States might eventually need all of the phosphates of the country, and that the plan of leasing would conserve the deposits and might prevent the exportation of the phosphate by provisions to that effect contained in the lease.

On this the report takes the view that there is no condition existing warranting the action proposed. There is said to be no necessity for alarm that the phosphate deposits of the country will be soon depleted or that there will ever be a phosphate famine or shortage.

PHOSPHATE RESOURCES

Returning to the question of exportation it is noted that outside of the United States there are very large phosphate deposits notably in northern Africa, in France, and in the South Sea islands. Our own western deposits are practically inexhaustible. The estimate made by the Geological Survey of 100,000,000 tons as the available phosphates in the field in Utah, Idaho and Wyoming was based merely on an estimate of the amount of rock contained in a 6-ft. seam on one consolidated claim multiplied by the estimate of the amount of the rock occurring in similar claims located on the outcrop of the deposits throughout the region.

"The estimate seems to have been very low," says the committee, "even for what may be called phosphate in sight—that is, phosphate on claims covering only the outcrop and extending but a short distance down the slope of the vein. Estimating on the basis of a 6-ft. vein, 10,000 acres would contain 100,000,000 tons, the amount estimated as available in this field. As above stated, upward of 4,300,000 acres of land were withdrawn from entry, and assuming that one-twentieth of this land contains a 6-ft. vein of phosphate, the available phosphate in the region would amount to 1,400,000,000 tons, which at the present rate of production in the United States, 2,250,000 tons annually, would furnish us with phosphate for over 600 years; or take the estimate that has been made by some that eventually we shall need 6,000,000 tons of phosphate annually for the fertilization of 400,000,000 acres of land, this field alone would furnish a supply for 233 years.

As the world's consumption of phosphate rock at this time is about 3,750,000 tons annually, it will be seen that the estimate of our possible ultimate use of 6,000,000 tons a year is high; besides we still have the deposits of South Carolina, Florida and Tennessee as well as other minor deposits in various other places in the West, and the probability of quite extensive deposits in Nevada and elsewhere in the Southwest. In short, there seems

to be but little more prospect of the exhaustion of the phosphate deposits in the United States than of the exhaustion of limestone, gypsum, and cement-making material, for all of which the demand, present and prospective, is very much greater than the present and prospective demand for phosphate."

Quincy Mining Company

The annual report of the Quincy Mining Company for the year 1908 gives the output of the mine as 20,000,361 lb. of refined copper which brought \$2,796,230. The profit from the year's operation was \$504,100, out of which \$50,000 was applied to the purchase of the Franklin lands. Four dividends were paid amounting to \$495,000 in all. Since the organization the company paid 86 dividends amounting to a total of \$18,450,000.

Much development, construction and reconstruction was carried on during the year. Six miles of opening work developed copper ground of about the usual quality. Although the output of the mine, both in ore and copper, was the largest in the mine's history, the reserves were increased. Sinking was carried on in all of the shafts and all proved average copper-bearing ground.

Platinum

The production of platinum in the United States in 1908 was 510 oz. According to the U. S. Geological Survey, the production in 1907 was 357 oz. Our report for 1908 is based upon the answers of all of the refiners in the United States to the inquiry as to the amount of crude platinum of domestic origin refined by them during the year. However, it is impossible to pronounce definitely that the metal reported was entirely of domestic origin.

Most of the domestic platinum passes through the U. S. mints. These do not make a business of refining platinum, but considerable of that metal is recovered as a by-product in the electrolytic refining of gold and silver bullion. The platinum is recovered in the slime, principally in the gold cells. There is no way of identifying its origin. It is associated with the gold bullion in such small quantities that its presence is not always noted; and inasmuch as the crude bullion comes into the mints from foreign as well as from domestic mines, it is probable that a portion of the platinum recovered is of foreign origin. The platinum is recovered at the mints in the form of sponge, furnaces for reducing it to bars not yet having been installed. Between 750 and 1000 oz. of platinum is recovered per annum. In 1908 only 500 oz. were sold, the price received being \$10.32 per ounce.

The refiners of platinum in the United States are the following:

Baker & Co., Inc., Newark, N. J.
Crosselmirre & Ackor, Newark, N. J.
S. S. White Dental Mfg. Co., Prince's Bay, N. Y.

Welsbach Company, Gloucester, N. J.
J. Bishop & Co., Malvern, Penn.
American Platinum Works, Newark, N. J.

Roessler & Hasslacher Chemical Company, Perth Amboy, N. J.

One of the refiners reported as follows: "We are in hopes that the day is not far distant when we may be able to obtain a dependable domestic supply, inasmuch as the manipulation of the market by foreign interests is decidedly unsatisfactory. That miners and prospectors are more than ever alive to the situation is evident by the frequent inquiries made of us and samples of domestic ore sent to us for examination, as a result of which we hope in the near future to be able to report materially larger purchases of domestic ore."

The business of platinum refining in the United States is of course much more important than the statistics of domestic production indicate, inasmuch as a great deal of foreign crude platinum is refined here, while a large amount of domestic scrap is refined or remelted.

Bureaucratic Intelligence!

Washington, Feb. 20.—Replying to a Senate resolution asking for a report showing the total amount of iron ore and pig iron produced and manufactured in the United States in any successive 12 months ending not earlier than June 30, 1908, the Secretary of Commerce and Labor, to whom the resolution was addressed, has informed the Senate that his department has no statistics on the production of iron ore or pig iron for any time since the census of manufactures of 1905, which covers the calendar year 1904, and, he says, the next census of manufactures will be for the calendar year 1909, and will not be taken until January, 1910, and will be ready for circulation about the summer and fall of that year. The secretary informs the Senate that compliance with the resolution would require several months' time and necessitate an enormous expense.

For detecting the presence of free lime in portland cement A. H. White (*Journ. Indust. and Eng. Chem.*, January, 1909) recommends the microscopic examination in polarized light for calcium phenolate, after crystallization has taken place, of a sample treated with a drop of special phenol solution (5 cc. phenol in 5 c.c. nitrobenzol with two drops of water added).

A Digest of Recent Coal Literature

Suggestions of Great Value and Discussions of Important Questions by
Engineers in Papers Read at Mining Meetings Held during the Winter

BY FLOYD W. PARSONS

It is impossible for the average man engaged in mining coal, to carefully read all of the many excellent papers written and presented by different authorities before the various meetings of coal-mining men, held in the different States. It is safe to say that all of these papers contain some points of vital interest to those engaged in the coal industry. The following digest is the result of an effort to condense the best thought in the different discussions. In many instances, the papers here referred to are most deserving of publication in full; however, this being impossible, it is hoped that some benefit may result from this method of brief treatment.

The Isolation of Certain Mine Areas from Contact with the After-Gases Created by an Explosion

BY NEIL ROBINSON*

After exhausting every known method for the prevention of accidents, we should endeavor to find some system whereby the effect of an explosion, when one does occur, may be localized. In almost every mine disaster, of which we have a record, the examinations have shown that the miners, alarmed by the concussion, have rushed for safety, only to meet death in the flow of the after-gas. Several hundred lives are lost from this cause every year. If the deadly gases generated by an explosion can be confined to the panel in which they originate, the men working in the other air currents may be saved. Further, if we can temporarily seal these free men in their panels, they will have an additional measure of protection until rescue parties can open the roadways to them. It is possible that this can be accomplished by a series of boiler-plate doors installed in the following manner:

Install near the main entry two boiler-plate doors on the intake and two on the air course of every panel. Recess the frames until they are flush with the ribs and roof. Face the frames with several thicknesses of canvas to make a close joint when the doors are closed. Hinge the doors on the overhead timbers and make a snug fit, swing the bottom of the doors to within 6 in. of the roof—one

pointing to the right and one to the left—and support in this elevated position by a detachable counter-weight or a flat trigger that can be displaced by an air pressure slightly in excess of the regular current, or by tripping levers controlled from partings. The frame timbers should have a sill extending across the entry, capped with planks to the top of the rail and also capped between rails except a narrow groove the width of a wheel flange.

Assuming that an explosion should take place near the advance heading of a butt entry, 1000 ft. from the main, the action would be about as follows: Before the gas generated can reach the main entry, it must compress and drive ahead this column of 1000 ft. of pure air and this pure air would blow out the supporting device and allow both doors to fall shut, at the same time operating the doors in every other part of the mine.

It is reasonable to suppose that the inner doors in the explosion panel will be blown from their fastenings, but this cannot take place with the outer doors. If the doors in a single panel in the mine are closed, the men behind them will be saved. We have evidence of the fact that men have traveled from 500 to 1000 ft. after the shock of an explosion. This clearly shows that there are occasions when time is given in which to operate an electric or hand device for closing the iron doors. A shock that would not kill the men running in an entry, surely would not be great enough to tear out the boiler plates swung at the entrance.

The protection here suggested may be inadequate; however, the plan has not been completed in all of its details, and is submitted in the earnest hope that it may prove the beginning of a work that will enable us to find a certain method of protecting our men from the deadly after effects of an explosion.

The Use of Electricity as Applied to Coal Mining

BY W. B. SPELLMIRE*

The increased use of electricity in mines has developed the idea of centralization in the generation of power. In the consideration of the relative cost of trans-

mitting power, it can be proved that the transmission can be made in the form of electricity over a wire with far less loss than it can be through a steam pipe, by compressed air or in any mechanical form.

Operators now realize that every ton of coal which is saved can be sold, and that it is a part of economy to save as many tons as possible. Where all power is generated in one power plant, one engineer and one fireman take the place of the same number in each of the many smaller plants. Coal and ashes can be handled more economically. Engines can usually be run condensing and repairs and maintenance are required for a few large power units rather than for many small units. It can be shown that the resultant saving is greatly in excess of the interest charges on the additional investment required.

DIRECT CURRENT OR ALTERNATING CURRENT

As to the choice in either the direct current or alternating current, the former can be used economically where the distance does not exceed a certain limit; beyond this specified distance, the cost of copper wire becomes prohibitive.

A given wire which transmits 250 kw. at 250 volts with a 10-per cent. drop, will, by raising the volts to 2000, transmit eight times the amount of energy, and this at only 1¼ per cent. loss. The cost of copper for carrying electric current depends upon the amperes to be carried; from this is apparent the desirability of keeping the current small. If it is desired to transmit a greater power at the lower amperes, it will be necessary to raise the voltage.

Direct-current generators cannot well be built to operate at higher than 600 volts. If a voltage greater than 600 is desired, it becomes necessary to use alternating current.

COST OF TRANSMISSION

If it were desirable to transmit 200 kw. to a mine one mile distant from the power house, the cost of copper for transmitting this at 250 volts direct current with 10 per cent. loss in transmission would be about \$26,000, and would weigh about 130,000 lb. The cost of copper for transmitting this same amount of power the same distance, with 10 per cent. loss at 2000 volts alternating current would be about \$300, and would weigh approximately 2000 lb. These figures show the

*Mining engineer, Charleston, West Virginia.

*Engineer with Allis-Chalmers Company, Milwaukee, Wis.

big saving in the cost of copper by the use of high-voltage alternating current. The cost of copper varies inversely as the square of the voltage.

Mining locomotives, coal-cutting machines, coke-oven larries, and coke-drawing machines are built only with motors for direct current. With alternating current delivered at the mine, it becomes necessary to change a part of this to di-

One of the most modern of central power plants has been erected by the H. C. Frick Coke Company, at Connellsville, Penn. This plant has a capacity of about 2000 kw. The heat for the boilers is obtained from a number of beehive ovens which are connected with flues so that the waste heat from the ovens is utilized. When the waste gases from coke ovens are utilized for generating steam, it is

dividual unit large. The Corliss type of engine will secure the best steam economy, and naturally the conditions will be improved if the engines are made compound and operated condensing. Operators should not attach too great importance to first cost; the higher economy is secured by installing the most economical engine.

Steam turbines as prime movers are

STEAM TURBINE GENERATING UNIT INSTALLED BY THE DELAWARE, LACKAWANA AND WESTERN COAL COMPANY. THE MACHINE SHOWN IS AN ALLIS-CHALMERS 2000 KILOWATT TURBINE

INTERIOR OF POWER HOUSE OF THE MCKELL COAL AND COKE COMPANY IN SOUTHERN WEST VIRGINIA

SUBSTATION OF YORK RUN PLANT OF H. C. FRICK COKE COMPANY, SHOWING ALLIS-CHALMERS ROTARY CONVERTER

rect current by the use of a rotary converter. For driving fans, pumps, crushers, and for rope haulage, alternating-current motors can be used to greater advantage than direct-current motors. In mining operations where compressed air is used, a compressor supplied with a large alternating-current motor can be placed at the pit mouth. The transmission of compressed air long distances is wasteful.

commonly assumed that each oven will furnish the equivalent of 18 h.p. This arrangement accomplishes a great saving and insures satisfactory results. The by-product oven will furnish about three times as much power as the beehive oven. The thermal efficiency of the gas engine is higher than that of the steam engine and boiler.

Where steam engines are used, it is best to centralize them making the in-

most desirable at coal operations. These turbines should be run condensing, and are not only economical in steam consumption, but combine large power capacity in small bulk; this reduces the cost of the power house building, as well as the cost of foundations. Steam turbines can be satisfactorily used in connection with noncondensing engines. It is possible by supplying a low-pressure steam turbine and condenser to frequently dou-

ble the capacity of the plant without adding any additional boiler capacity or requiring any additional fuel.

The Barren Zone of the Northern Appalachian Coalfield

By I. C. WHITE*

Instead of a continuous sheet of coal measures underlying the entire Appalachian region, there is a great barren zone, which in the Allegheny series, begins a few miles north from Pittsburgh, and embracing most of Allegheny county and large portions of Westmoreland, Washington, Greene and western Fayette, as well as southern Beaver counties, passes southwardly entirely across West Virginia and southern Ohio, thus reducing enormously the productive area of the Allegheny series, and its usually estimated coal resources.

This fact has been brought to light principally by the oil-well drillers in the search for petroleum and natural gas. The effect of this barren zone on West Virginia's productive coal area is to reduce it from 17,000 square miles to only about half that size, and the tonnage which has recently been estimated at 231,000,000,000 is reduced to about 60,000,000,000 of first-class available fuel. The 112,000,000,000 tons of bituminous coal originally existing in Pennsylvania, and 86,000,000,000 in Ohio, as estimated by Mr. Campbell, are also greatly reduced. It is quite certain that Pennsylvania will not furnish more than 40,000,000,000 tons, and Ohio probably not more than 25,000,000,000 of commercial bituminous coal.

The question as to why no valuable coal beds were formed in this great central trough is most puzzling. The reason for this condition appears to be due to the fact that the central region of the Appalachian coalfield was covered with water to such a depth that vegetation could not secure a foothold, and hence while sediments accumulated there to practically the same thickness as in other portions of the basin, they consist only of shales, sandstones and limestones, the latter being in greater proportion than where the coal accumulated in commercial quantities. Of course, there will be some islands of commercial coal in this long and broad barren zone, but they will be local and of small extent.

The Pittsburgh region, therefore, instead of having a supply of coal sufficient to last for 200 years, has only enough coal to last 50 or 60 years, providing present wasteful mining methods continue. West Virginia has only about the same acreage of the Pittsburgh seam as Pennsylvania, while Ohio's coal area will

be practically gone in 25 years. It is possible, therefore, that Pittsburgh industries, 50 years hence, will have entered upon the expensive method of mining coal by deep shafts to beds of inferior quality, and of only 1 to 2 ft. of thickness. This condition is as sure to come to pass, if present methods continue, as that the sun will rise tomorrow.

SOME OF THE SOURCES OF WASTE

The citizens of Pennsylvania have already wasted more of their precious fuel supplies, both solid and gaseous, than they have ever used. More than 30,000 beehive ovens continue to waste approximately one-third of the fuel value of all the coal burned in them. As an example of waste, one oil well in West Virginia permitted 12,000,000 ft. of gas to escape each day in producing only four barrels of oil; this spectacle of wasting the heating value of 12,000 bushels of coal daily, together with the power to deliver itself free of charges for transportation, is not an isolated case. One great gas company operating in West Virginia put into its line nearly 100,000,000 cu. ft. of gas daily and delivered in Pittsburgh much less than half that quantity, the larger portion having escaped into the air through defective joints of cheap and imperfect pipe-line construction.

Why should we permit the use of wasteful beehive coke ovens, which continue to vomit skyward such enormous volumes of precious gaseous fuel, which wasted energy will soon be needed by our great factories? The superiority claimed for beehive coke does not in the least warrant such waste. Why should we retain the steam engine to consume with frightful speed, our best fuel, when more power can be obtained by the use of the gas engine, from an equal weight of impure or low-grade coal? Fortunate would it be for our country's future, if some master genius could arise, and at one stroke, relegate both the steam engine and the beehive coke oven to the junk heap.

Conservation in the Coal Industry— Protection of Life and Prevention of Waste

By GLENN W. TRAER*

After years of experience, I can honestly say, as far as my knowledge goes, that all laws which have been animated only by a sincere and honest purpose to protect employees from death and accident, from any cause under the control of the employer, have met with the prompt obedience of coal-mine owners. For all practical purposes, the Illinois mine law gives

*President, Illinois Coal Operators' Association.

the present miners' organization in that State, an absolute monopoly of mining labor. The law provides that the examining board for the admission of new miners shall be drawn from the ranks of the miners only. No other interest is recognized in the appointment of such boards. Resentment and opposition to such laws will certainly continue.

The steam-engine method of producing power and the fearful waste of by-products in the manufacture of coke in beehive ovens are practices that should no longer be tolerated. It may be that certain regulations broadly and properly designed for the safety of human beings may also tend toward the conservation of coal. For illustration, a requirement that all coal mines opened after a certain date should extract the coal only from the outer boundaries of the property toward the outlet of the mine. This would avoid the existence of any gob, would lessen the danger of gob fires, decrease the number of accidents from falls of roof, would improve ventilation and lessen the danger of explosions spreading throughout the mine. This method would also insure a greater extraction of the coal area.

HIGHER PRICES FOR COAL

The right of the present generation to use effectively of these coal resources, what it actually needs, carries with it a sacred obligation not to waste this precious heritage. We cannot expect the men of this generation to mine our resources in such a manner as to entail continuous financial loss; it is therefore reasonable to expect that the users of mineral products will pay for them much higher prices so as to make profitable their mining and preparation without serious waste.

Our present statutory anti-trust laws wholly ignore the natural principles that reasonable competition and reasonable combination are natural counter checks upon each other. The English nation maintains the only true protection against the evils of monopoly; this English law forbids only such restrictions or regulations of competition as are hurtful to the people as a whole. Unregulated competition does not result in the survival of the fittest, it is more often the survival of the most cunning and aggressive.

Each brief period of unusual prosperity results in an increase of the number of coal mines and in their production capacity, far beyond the public requirement. The excessive producing capacity of the mines now in operation in Illinois results in a loss of at least 50 days' work per annum to all miners and mine laborers on the pay-roll, more than 70,000 in number. This is equivalent to the absolute idleness for the entire year of at least 12,000 men.

The excessive number of mines kept

*State geologist, Morgantown, W. Va.

open, causes a scarcity of miners and makes it necessary to accept the services of inferior men. Such conditions in a great industry are a public evil, even though they result in lower prices to consumers.

Existing anti-trust laws should be amended so as to permit intelligent organization of disorganized industries, while preserving at the same time such a degree of publicity and public regulation as are necessary to protect the interests of the people as a whole. Wise economic results cannot be expected under unwise economic laws.

Progress in Coke-Drawing Machinery

By W. L. AFFELDER*

The introduction of coke-drawing machines has made it possible to effect a decided reduction in the first cost of erecting a coke plant. This economy results from the fact that where yards are built exclusively for the use of machines, yard-walls can be omitted as well as the expensive yard filling. Where machines are introduced upon old yards, it is necessary to widen the doors of the ovens to at least 42 in., and to grade the yards so that the machine track is 41 in. below the door-plate for the older type of Covington machine and 28 in. for the newest type.

The introduction of machines also effects a decided reduction in labor cost in drawing coke, inasmuch as coke can be watered, drawn and loaded, the ovens cleaned and a new charge leveled at a labor cost of but 35 to 40 per cent. of the cost of hand-drawing. Much of this saving, however, is offset by other items of expense, such as the cost of electric power and mechanical repairs on the machines. It is also true that where machines are used more coke is lost in the shape of ashes and braize.

To water, draw and level 30 ovens, 16 to 20 coke-drawers and two levelers would be necessary, while the same amount of work could be done satisfactorily with one waterer, two machine men, one oven cleaner and two levelers; that is, six men would do with a machine the work of three times their number under hand-drawing.

In an attempt to reduce the number of laborers required, as well as to overcome the defects of coke-drawing machinery, coke manufacturers have recently departed from the long-established practice of building beehive ovens, and in several instances have built plants of rectangular ovens from which the coke is removed

by pushing machines. The general practice has been to build these rectangular ovens about 5 ft. wide, with the discharge end 2 in. wider than the pushing end, 32 ft. long, 7½ ft. high to the bottom of the trunnel head and 26 to 29 in. between ovens. While it has been possible to make a good coke in these ovens, more economical and durable doors must be devised, lining brick better adapted to resist the effect of water and abrasion must be selected, and a satisfactory device designed to water the coke economically.

While much progress has already been made in the development of coke-oven machinery, the future field is still a promising one for ingenious inventors.

The Installation of Electric Power in Coal Mines

By W. A. THOMAS*

Electricity has often been blamed for accidents in coal mines, where many other causes might as consistently have been found. In the effort to determine precautionary measures for the safety of employees, it is a serious question as to what limitation should be placed on the use of electricity in coal mines. It is recognized that many of the suggested changes in methods of mining must necessarily increase the cost of coal production, and to adopt the changes in one State and not in another, must necessarily work to the disadvantage of the industry in the State making the most reforms. Some of the States have attempted to inaugurate reforms through legislation; however, in the majority of cases, the new rules have been found to be ineffective and inoperative. It may generally be considered that a safe voltage is anything up to 600 volts direct current.

Mines should be classified as follows:

1. Gaseous mines sufficiently dangerous to forbid the installation of electrical equipment.
2. Gaseous mines where the volume of inflammable gas generated is so small that it may be good practice to install safety lamps and safety powder, but will not preclude the installation of electrical equipment.
3. Non-gaseous mines where electric machinery is operated with direct current, and where 600 volts or less may be installed.

Where electrical equipment is installed, the tracks should be bonded and regularly inspected; they should also be cross-bonded every 200 ft. No permanent wire, either feed or trolley, transmitting 600 volts or less, should be insulated; the mine air soon affects the insulation and men are liable to be deceived, believing

they are handling an insulated wire. It is better to teach men to keep hands off all wires. The trolley wires should be erected at a uniform height from the rail and a uniform distance, about 6 in., outside the outer edge of the rail. As a guide to men traveling on the main road, lights should be placed and maintained every 200 ft. Where trolley wires cross the main heading, they should be protected by an inverted wooden trough and lights put at both ends of the trough.

PRACTICAL SUGGESTIONS

Switches should be of an approved type in boxes. Each motor and each locomotive should have an inclosed copper wire fuse on the main circuit. All forms of stationary motors should have the frames grounded in an approved manner. Controller frames on electric locomotives should be grounded to locomotive frames. Lightning arresters should be placed at the entrance of the mine. Where mining machines or drills are used in rooms, the frame of motors should be grounded to the frame of machines, and machines connected to the return circuit. Where it is necessary to install wires in rooms, have an approved automatic cut-out or switch, and have installed in the rooms in view of the miners, two lamps in multiple.

Where mines are ventilated by electric fans, an alarm should be so arranged in the power house that when fans stop the power-house engineer will get a signal. If the mine is gaseous, he should have instructions to cut power off the mine at once and immediately start an investigation as to the cause of the fan stopping. As much as possible, fan circuits should be separate from all other circuits.

Coincident with the adoption of uniform standards in installation and operation, steps should be taken to provide the State mining department with men especially skilled in the use of electric power in mines.

Development of a Virgin Coalfield

By F. H. PALMER*

Prior to the expenditure of time or capital, there are three propositions which should be considered in the initial development of a coalfield: 1. Is the location of the tract such as will enable shipments to be made in an economical manner? 2. The competition to be met with in the available markets. 3. Is there an abundance of labor near the tract or can it be secured? If the above conditions are favorable, the work of prospecting should begin.

Having located the different seams on the tract, and opened them up at

*Superintendent, Brownfield plant, H. C. Frick Coke Company.

*Commercial engineer, Westinghouse Electric Company, Pittsburg, Penn.

*General manager, Oleott Coal and Iron Company, Oleott, West Virginia.

regular intervals, the next step is to discover the quality of the coal and to secure samples showing the true sections of the different seams. All partings which would be thrown out in mining, should not be included in the sections. If the coal is to be used for the manufacture of coke, it is best to secure a large enough sample to make a practical test, as this is the only positive way that coal can be judged as to its coking properties. When the coal seams are below water-level the property should be tested by boring.

The next step is to find the true dip of the different seams by a series of levels. The next consideration is the location of the railroad. If the seams are above water-level, the railroad should be located so that the different beds can be opened at the lowest point. This will reduce the cost of haulage and drainage.

OPENING UP THE SEAM

There are three methods in general use for opening up coal seams, namely: Shafts, slopes, and drifts. Shafts may be circular, square, oblong or rectangular. The latter is generally used in this country. The long side of the shaft should be as nearly as possible parallel with the line of dip, as this will necessarily place the ends of the cage in line with the strike of the seam, and the charging of the cages can be easily accomplished.

In sinking the shaft it is necessary to sink it 3 or 4 ft. larger each way than the actual size that has been determined. This size should be continued to a depth sufficient to secure a solid foundation for the side walls to rest upon. These side walls furnish a permanent foundation for the headframes. If water is encountered in sinking, it may be provided for by what are commonly known as "water-rings," from which, on the completion of the shaft, the water may be piped to the bottom.

Where the seam has a dip of 20 deg. or more and the outcrop is on the property, a slope may be started from the surface in the seam of coal to be worked. When the seam is comparatively flat and near the surface, it may be opened up by a slope driven through the overlying measures. When the slope is driven in the coal seam, the slope and air course are usually driven side by side; however, where the slope is driven through the overlying measures, a shaft is sunk nearby to serve as an airway.

If the slope has been sunk in the coal, it is usually desirable to drive to the limits of the property, and at this point, install the permanent pump, forcing the water through a borehole to the surface. Sinking the slope through the overlying strata is very expensive, and insures but little additional advantage.

Mining Methods of Western Pennsylvania from the Standpoint of the Mine Operator

By FRED C. KEIGHLEY*

There is as much room for improvement in mining methods today as there was 10 years ago. Some objection may be taken to the mine manager's seeming solicitude for the safety of the investment, but unless mining properties return the investment, there certainly would be no such properties in existence today. We must be fair to all when we consider the question of interest on investments; it is essential therefore, to treat labor and capital upon an equal basis; we cannot make a standard for one and not for the other.

The coal operator is chiefly concerned as to how he can secure the greatest tonnage of coal from his whole area with the greatest degree of safety to the miner and the highest return to the owners of the property. It is true that we are rapidly exhausting our resources, but we are not removing them exhaustively. We leave too much of the coal seam behind us.

WE SHOULD EDUCATE OUR MINERS

Our miners today are only so-called miners, and mine superintendents are continually thwarted in their purposes by the enormous proportion of raw labor material that is taken into the mines daily. This raw material is the real cause of waste and is largely responsible for the many disastrous accidents.

No further improvement in mining methods can be expected until we have better material from which to build up our miners. No great difficulty should be experienced in doing this, for in many other lines of industry, much good has resulted from efforts directed toward educating the worker. When this is done greater security and greater yield from our coal seams will result.

The Testing of Miners' Oil

By C. E. SCOTT†

Aside from the necessity of carrying out the requirements of the law, there are advantages in supplying the miners with the best oil obtainable. An oil of high viscosity does not flow freely and offers a greater amount of resistance than one of low viscosity. As a general rule, an oil of high viscosity will not keep lighted on headings and air courses where strong air currents are met; it is

also hard to relight, and feeds up the wick very slowly.

The congealing point of an oil is an important factor in the winter months. The congealing point is the temperature at which the oil will solidify. Although the temperature inside the mines varies but little, the roadmen, drivers, motormen and others come in contact with air that is almost as cold as the outside atmosphere, consequently when buying winter oil, there should be a guarantee that it will not congeal at a temperature above 32 deg. F. The winter oil used by the Fairmont Coal Company shows a congealing point of 21 deg., which allows it to be stored and handled in cold places without freezing.

The height of flame is also an important consideration in the purchase of oil. One company that has given this subject much attention, specifies that the oil shall give a height of flame between 4 and 5.5 in., with the wick extending $\frac{1}{4}$ in. beyond the end of the lamp stock, with a 12-strand wick. This height has been found to produce the best candle-power with the least amount of smoke; if the height of flame is limited, the evolution of smoke is to some extent controlled.

THE SMOKE PROBLEM

In testing miners' oil there is probably nothing of greater importance than the quantity of smoke it gives off while burning. An inferior oil always makes denser smoke. This point guides the mine inspector in his inspection of the oil used at different mines. When oil gives off an excessive amount of smoke, it may generally be assumed that it is adulterated and not up to the standard required. An oil to which kerosene has been added (which is common practice in most regions) is the greatest offender in this direction.

While it is true that drivers, motormen and trappers spend most of their time in an air current of high velocity, oil can be purchased for them that will burn with a long flame and hold to the wick under most severe conditions, and still come up to the standard specifications. The consumption of oxygen due to the burning of oil in a miner's lamp is very small in amount, since it has been figured that only one-seventeenth of the total pure air in a mine is required by the miners, horses and lamps. It is the quantity of smoke given off that causes the greatest vitiation of the mine air.

To measure the quantity of smoke given off by any particular lamp, use pure cottonseed oil as the standard of comparison. The size of lamp, length of wick, and quantity of oil should be the same in each case. The lamp should be placed in a box with a glass front and a white cloth, graduated in inches, to serve as a background on which to measure the length

*General superintendent, Oliver & Snyder Steel Company, Uniontown, Penn.
†Chief of testing department, Fairmont Coal Company, Fairmont, W. Va.

of the smoke pencil. The limit placed on the smoke is a pencil about 1.5 in. greater than that of the standard cottonseed oil.

The present specification on miners' oil as adopted by the Fairmont Coal Company reads as follows:

Density—24 deg. B. or under.
 Congealing point—24 deg. F. or under.
 Flash point—300 deg. to 425 deg. F.
 Flame light—Between 4 and 5.5 in.
 Equivalent candle-power per grain per minute—8 or over.
 Smoke—To be light in quantity.

Coal Mine Legislation

The mines committee of the Indiana Legislature held a number of sessions during the past week at which miners and operators appeared in advocacy and opposition to measures being advanced and placed for passage. The "Kayser bill" to create an examining board and the issuance of certificates for miners after an apprenticeship of two years, and the "Mugg bill" providing safer means of escape from mines in case of explosions were discussed. These bills were instigated by the mine workers and are opposed by the operators. The miners contend that the present means of escape from mines make it practically impossible to reach daylight in case of an explosion, and demand hoists in safety shafts.

A bill providing for heavy penalties for any dealer to sell fuel in which any foreign substance is contained, has brought coal and gas men to the capital to oppose the bill. Gas men say it is impossible to transmit gas entirely free from air and likewise the coal men declare it is impossible to produce coal absolutely free from impurities. An amendment to exempt coal companies was voted down and the bill passed the Senate. The fight will now be transferred to the House.

A bill prohibiting mine owners from taking out indemnity insurance against damages recoverable in case of injury or death to employees has been killed, and a bill passed allowing administrators to bring suit in favor of widows and children in case of death of the husband in a mine.

The Judiciary committee is wrestling with a bill calculated to prevent the rebuilding of the DuPont Powder mills at Fontanet, where an explosion a year ago killed 28 people. The terms of the bill are such as to make it impossible for the powder mill to be operated in Indiana. Strong efforts are being made to modify or defeat the bill.

A bill will be reported out of committee for passage this week which provides for the appointment of the Chief Mine Inspector by the Governor on recommendation of the miners, and operators of the State, instead, as now, being appointed by the State Geologist. This is regarded as a partisan measure and will not likely be approved by the Senate.

Colliery Notes

Dust explosions occur in two stages: The ignition of the dust particles, and the explosion of the resulting and ready-formed gaseous products. These two phases follow in such rapid succession that they practically form one operation.

Recent experiments show that $\frac{1}{2}$ oz. of coal dust per 35 cu.ft. of air will suffice for the production of an explosion. It was also found that it is more a question of fineness of the division of the dust, than the weight, that causes a condition of great danger.

It is well for coal operators that economic laws so largely govern the industry. Human devices may control prices temporarily, but in the end natural conditions must prevail. The more nearly prices and wages conform to economic conditions, the more speedily will business return to a normal basis.

In considering the distance to which currents can be carried through cable of a given size, the following rules should be remembered: First, the loss of voltage, other things being equal, is exactly proportional to the length of the cable; second, the loss of voltage on any given length and size of cable is proportional to the current as measured in amperes; third, the loss of power on any given circuit is proportional to the square of the current.

In electric shot-firing, the firing line must always be paid-out from the shot-hole to the place of safety. If the shot-firer has occasion to leave the firing line, even momentarily, after having paid it out, he should take the exploder with him. After a shot has been fired, the shot-firer should immediately disconnect both ends of the cable from the exploder, free it from any chance debris which may have fallen upon it, and coil it up. This routine should be followed even when a misfire has occurred.

The extent to which electric motors are applicable in the case of engines, such as winding, pumping, and haulage engines, is a question requiring careful thought. As a general rule, the electric motor is applicable to all small engines, and to large engines which run continuously, such as fan engines and pumping engines; however, when applied to haulage at high speed, where there is a continual starting and stopping, the advantage of the electric motor is less apparent. If the haulage is done by endless rope and is practically continuous for eight or ten hours a day at a uniform speed, then the electric motor is eminently suitable.

At a recent meeting of mining men at Cardiff, Wales, a prominent mining engineer propounded the theory that a huge force may be suddenly developed by the

primary explosion in a coal mine, and that parts distant from the originating center, and free from gas, are devastated as the result of enormous pressure set up by the first explosion. The exponent of this theory stated that many men were instantaneously killed by an explosion before any sound reached them to warn them of danger. One instance was cited where a miner was found dead sitting with his head on his knee. Another instance was that of a man who was found dead actually standing with a drill in his hand after an explosion in the Universal pit, South Wales. Another instance upholding this percussion theory was that of two horses being killed, in whose blood no trace of carbon monoxide could be found.

The following table has been found to be approximately correct, and will be of use to those who test for gas with a safety lamp:

- 1 vol. firedamp to 60 vol. air = 1.66 per cent. It is just possible with very good eyesight or with the help of a magnifying glass to distinguish a minute cap above the small oil flame.
- 1 vol. firedamp to 50 vol. air = 2 per cent. An exceedingly faint cap, $\frac{1}{2}$ in. high, the top having the appearance of being broken off.
- 1 vol. firedamp to 40 vol. air = 2.50 per cent. A conical cap $\frac{3}{8}$ in. to $\frac{1}{2}$ in. high.
- 1 vol. firedamp to 30 vol. air = 3.33 per cent. A conical cap, $\frac{1}{2}$ in. high.
- 1 vol. firedamp to 25 vol. air = 4 per cent. A conical cap, $\frac{3}{4}$ in. to 1 in. high.
- 1 vol. firedamp to 20 vol. air = 5 per cent. A cap $1\frac{1}{2}$ in. high, cap perfectly steady and more distinct than any of the others.
- 1 vol. firedamp to 18 vol. air = 5.55 per cent. A similar cap, 2 in. high, which burned rather more steadily.
- 1 vol. firedamp to 16 vol. air = 6.25 per cent. Gave a voluminous, wavy, spindle-shaped, pale blue cap, $3\frac{1}{2}$ in. high.
- 1 vol. firedamp to 15 vol. air = 6.60 per cent. Inflamable.
- 1 vol. firedamp to 14 vol. air = 7.14 per cent. Slightly explosive.

The latest invention for indicating the presence of firedamp in coal mines, has been perfected by a German miner and depends upon the fact that the electrical resistance of selenium decreases when exposed to light. In using the apparatus in mines, a cell containing selenium is placed in an electric circuit containing a relay and a battery. Under normal conditions the selenium cell is exposed to the bright beams of a Davy miner's lamp. The rays of light from the lamp cause the selenium cell to offer a comparatively small resistance to the current of the battery with which it and the relay are in circuit, so that the relay exerts a comparatively powerful pull on its armature and keeps it attracted. If the lamp becomes surrounded by firedamp, its light becomes duller and the resistance offered by the selenium rises, so that the current flowing through the relay is weakened. In consequence of the decrease of attractive force of the electromagnet of the relay, its armature is pulled back by a spring against a contact which closes an alarm circuit. This causes electric bells to be rung at all the necessary points, thus indicating the presence of firedamp at the spot where the miner's lamp is placed.

THE ENGINEERING AND MINING JOURNAL

Issued Weekly by the

Hill Publishing Company

JOHN A. HILL, Pres. and Treas. ROBERT MCKEAN, Sec'y.
509 Third St., New York, N. Y.
London Office: 6 Bouverie Street, London, E. C. 4, Eng.
Cable Address: "ENGINEERING, N. Y."

Subscription, payable in advance, \$5.00 a year of 52 numbers, including postage in the United States, Mexico, Cuba, Porto Rico, Hawaii or the Philippines, \$6.50 in Canada.

To foreign Countries, including postage, \$8.00 or its equivalent, 33 shillings; 33 marks; or 40 francs.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday, a week before date of issue.

For sale by all newsdealers generally

Entered at New York Post Office as mail matter of the second class.

CIRCULATION STATEMENT

During 1908 we printed and circulated 507,500 copies of THE ENGINEERING AND MINING JOURNAL.

Our circulation for February, 1909, was 42,000 copies.

March 6..... 12,000

None sent free regularly, no back numbers. Figures are live, net circulation.

The Change in Feeling

It was not to be expected that the reductions in the prices for steel and copper would be immediately followed by a revival of the demand for those products. Insofar as ultimate consumption is concerned, we doubt if there has yet been any material change. In that phase of the question, the situation is still one of slow, but gradual, recovery. On the other hand, it is undeniable that during the last week there has been a perceptible change in the feelings of those who make it their business to discount the future.

Only a week ago nearly everyone was in the slough of despondency. Gossip was beginning to circulate about a curtailment of copper production. "I should not be surprised if the Butte mines were closed unless there be an improvement in the near future, although Mr. Broughton is a stumbling block which may prevent this action, for he takes the dog-in-the-manger position that somebody else may be benefited through such action," said a certain copper producer. (Why Mr. Broughton should be criticized for not closing mines which can produce copper at 10½¢. per lb. is beyond our comprehension.) However, it appeared probable that some curtailment would be effected by the suspension of operations at those mines of which the cost of copper is 12½¢. and upward, whereby supply would be gradually adjusted to demand.

The situation in the iron and steel industry was more or less similar. In short, trade was much in the position of the sick man, ailing for a long time, but unwilling to undergo the necessary operation. The latter having been finally performed, the vitality of the patient is low, and while recovering from the effects of the ether he feels sicker than ever, but this lasts for only a short time.

In the case of copper, it was obvious that the price was approaching the bottom, inasmuch as it was nearing the cost of production. The halt would naturally be caused when speculators and manufacturers felt that they were able to pick up the metal at a bargain. The beginning of such a movement occurred on Feb. 24, since when there has been large selling, chiefly for foreign account. Domestic manufacturers have so far continued reluctant to buy, although in some cases it is certain that their supply is becoming low. Whether they will be induced by the

stiffer attitude of the selling agencies since March 1 to make haste remains to be seen. So far their continued inaction has been rather disappointing. Probably no one is afraid, in view of the large stock of metal on hand, that there will be any runaway market. On the other hand, the producers are now in a more comfortable position than to days ago. The present outlook is for a period of fluctuations within a comparatively narrow range, during which demand and supply will become adjusted, first of all by the retirement of the high-cost producers.

The Anthracite Miners' Demands

The labor situation in the anthracite region is becoming critical as the date for the expiration of the present agreement approaches. The demands for the new agreement have been formulated by the local unions and approved by the National association. As usual, they probably include much more than the miners expect to get. Briefly stated, they include the reduction of the working day from nine to eight hours; the substitution of the ton for the carload as a basis of payment to miners; the use of the short ton, of 2000 lb., in place of the long ton which has always been the customary measure; and an increase of 5 to 10 per cent. in wages of day-workers. Finally—and this is the main point—they insist that the operators shall deal with the union directly; that all questions arising under the agreement shall be settled with the organization; and they demand the check-off system, under which the operators deduct the union dues from the miner's pay-roll. That is, the open-shop system which has prevailed since the settlement of 1903 shall be abolished, and the anthracite collieries closely unionized. This is emphasized by the appointment of a committee including a number of soft-coal miners, headed by the president of the United Mine Workers, to present these demands.

While no official statement has been made, it is well understood that the anthracite companies will refuse all of these demands; and it is highly probable that they will refuse even to negotiate with the committee appointed, though they are willing to discuss the situation with actual representatives of the workers in the mines. They claim that the present agreement—which is practically that formulated

by the Anthracite Strike Commission in 1903—has worked well both for miners and operators. They object to the abolition of the Conciliation Board, which has been a valuable feature of that agreement. Especially do they object to the exclusive unionizing of the region, which means to them practically the operation of the collieries subject to the dictation of the walking delegate. The wage increases are not considered as of importance—though they will hardly be granted under present conditions—as they are believed to be merely a makeweight and subordinate to the union demands. They also object strongly to an agreement limited to one year.

It does not appear that the anthracite miners have any substantial grievances to be redressed. The general conditions in the region have been better than ever before. The real reason for the demands is found in the fact that the unions have been losing heavily in numbers, many members dropping out by their failure to pay their dues. A new fight seemed to the leaders to be the shortest way, or perhaps the only way, to rehabilitate their organization. For this reason it is doubtful whether the movement will have any public support. On the other hand, the companies are in a strong position. The season is approaching when the demand for coal is comparatively light; and they have accumulated stocks sufficient to carry their trade for some time.

That there will be a strike in the anthracite region seems now to be a foregone conclusion. As to its probable duration only conjecture is possible. It is to be hoped, however, that the State authorities will take warning, and will be prepared, should the strike last, to prevent any repetition of the disgraceful disorder which has marked previous industrial troubles in the anthracite country.

"Open Markets"

It seems strange that the daily press cannot learn some of the simple facts of the metal industries. Last week the cutting of prices by the Steel Corporation introduced the phrase "open market," which caught the popular fancy. There had previously been an open market in iron and steel. All that the great corporation did was to enter into competition with the independent producers, who had been cutting prices and securing the business that was going. The market had been "open" enough.

Then it was announced that there was to be an open market in lead, the American Smelting and Refining Company being about to enter into competition with the National Lead Company. This was enough to make a blast furnace laugh. The National Lead Company produces some lead for its own consumption, but it is the largest customer of the American Smelting and Refining Company. The latter indeed has a stock interest in the National Lead Company and is represented on its board of directors. The smelting company controls a large production of lead, but in this metal also there has been decidedly an open market ever since prices began to crumble away, two years ago.

The same thing is true of copper. In this metal there is no trust and there never has been. There has been no understanding among the producers since the Secréan affair, about 20 years ago. Some of the large interests in this industry at the present time are friendly; others are hostile; the relations are such that there is not, and has not been, any prospect of affiliation, or even any talk of it except in quarters where the wish may have been father to the thought.

The situation in copper is simply this: The Amalgamated Copper Company is a large producer. Its copper is sold by the United Metals Selling Company, in which the inner circle of the Amalgamated company is the controlling interest. The Metals Selling Company also handles the copper of other producers under contract and for a commission. In this way it has the disposal of a larger amount of metal than any other single interest. However, there are five other selling agencies of first magnitude (each disposing of upward of 100,000,000 lb. per annum), besides a large number of smaller concerns. These compete aggressively for business. The market is always open.

Such confusion as exists respecting this is fundamentally the result of concentration of business in comparatively few hands, and especially the development of a giant, who is at times of dominating influence, and again is comparatively helpless. The zinc industry has undergone concentration during the last 10 years, which has had an effect upon the spelter market, but no Goliath has appeared and consequently there has never been any suspicion of the market being otherwise than open. In the other industries—steel,

lead and copper—the U. S. Steel Corporation, the American Smelting and Refining Company, and to a much less extent the United Metals Selling Company, have attempted to regulate prices. Their managers became intoxicated by their apparent success in that direction and failed to perceive that this was achieved on the general rise in the markets that coincided with the era of great industrial consolidations. However, in summing up the experience of the last 10 years, we are able to deduce an economic axiom as follows:

A corporation controlling a large percentage of production can regulate prices when consumptive demand is large and the trend of prices is consequently upward, and may continue to do so during a temporary setback, but it cannot govern prices when there is a serious or prolonged recession in business and a naturally downward trend of prices.

The Calumet & Hecla—Bigelow Settlement

The litigation which has been pending for some time between the Calumet & Hecla Company and A. S. Bigelow over the control of the Osceola Mining Company has been finally settled by something in the nature of a compromise. The Calumet & Hecla bought a large interest in the Osceola about two years ago; it was not a controlling interest by itself, but the company secured the support of other stockholders who had long desired to see the Osceola free from the Bigelow control. Mr. Bigelow, however, brought suit to enjoin the Calumet & Hecla from voting on its stock, and by appeals and other legal devices he succeeded in postponing the change of control up to the present time. It does not appear that he hoped for ultimate success, but chiefly that he wished to secure delay, and acquire a good strategic position for the sale of his stock. The judgment of the courts was for the most part in favor of the Calumet & Hecla, but the litigation could have been prolonged still farther, and the present settlement was made.

An incidental result will be that the sale of the copper from the Bigelow mines will pass from the United States Metal Selling Company as soon as existing contracts expire. The Calumet & Hecla selling agency will doubtless handle and market the product of all the mines.

American Institute of Mining Engineers

The ninety-sixth meeting of the American Institute of Mining Engineers opened on Tuesday evening, Feb. 23, in North Sheffield hall, Yale University, New Haven, with about 50 members present besides many professors in the Sheffield Scientific school and students who are taking the mining courses in that institution. Neither John Hays Hammond, the retiring president, nor D. W. Brunton, the new president, was able to attend, and Dr. James Douglas presided at the opening session. Director Chittenden, of the Sheffield school welcomed the members of the institute to New Haven.

Doctor Raymond announced that two honorary members and one honorary associate member had been elected by the council. These are Prof. Richard Beck, of Freiberg, Emil Schroeder, secretary of the German Society of Iron Masters, and James F. Swank, of Pittsburg. He also announced that the next meeting of the institute would be held next fall on the Pacific coast at Seattle. Before going to Seattle those who are to attend the meeting will go to Yellowstone Park, from there to Spokane and from there to Seattle, after that going to Salt Lake City, with a chance for a side trip to Goldfield, Nev.

Doctor Douglas then read a paper on "The Conservation of Natural Resources." The paper was confined to mineral resources and read in part:

CONSERVATION OF NATURAL RESOURCES

"Complete recovery of every ingredient in an ore is impracticable, and it is a question for the conscience what to throw away and what to save. When I went to Arizona in 1880, the copper industry was in its infancy. Most of the companies wasted large amounts of copper with the refuse that was thrown away; it is only because of the advent of the railroad lines that the companies are being profitably conducted. There was a stripping of every hillside of its trees for fuel before the railroad brought coal there, and in every department there was waste of labor, capital and resources. "There is great waste in anthracite coal, but this is being recovered today. I am not fond of trusts, but it must be admitted that great capital and costly experiments are needed for the conservation. All great improvements have been made under the direction of large corporations with large capital. We are in duty bound to help in the work of saving.

"Technical men for the past two generations have been seeking to save waste, and the criticisms of the public concerning our work will not reduce the waste at all. Looking back a generation or two we see how much has been done

toward saving. This is shown in the pig-iron industry where early in the last century hundreds of square miles of forest timber were burned to make a relatively small amount of pig iron.

"People say that the coal resources will be gone in 150 years; that iron will be gone; it doesn't matter. Some substitute will be found for each, or our children will be greater fools than ourselves."

In discussing the paper Doctor Raymond said that the national executive and the national congress had destroyed a great deal which had been accomplished toward the conservation of natural resources. Ever since the first meetings of the institute committees had been working on the coal question, one of which was later made the official commission of the State of Pennsylvania. The corporations, mainly the railroads, secured control of the coalfields of Pennsylvania, and the natural desire to improve the property, and to have a transportation business even after the lease of the fields had expired, led to the expenditures of large sums to prevent waste and to utilize to the greatest extent the products. Then the national legislature decided railroad corporations could not own the coalfields. This, said Doctor Raymond, is what politicians and hysteria on the part of the public will do. Doctor Raymond also quoted from a paper presented by him and W. R. Ingalls, in collaboration.

E. W. Parker read a paper on "Coalfields of the United States." He said in part:

"The greatest reason for waste in the bituminous-coal region, was the idea of getting out the greatest amount in the shortest possible time. Today 70 per cent. is saved. I think that by the time the coal is exhausted, the need for it will have passed. But I do not think it a waste of time to have an inventory of what we have and see how fast what we have is being consumed. We have found that the coal supply will be exhausted by the middle of the next century. I do not think that it is right to export coal or other raw material, and this practice should be discouraged. Nothing has done so much to conserve the anthracite supplies as the corporation control in Pennsylvania, and it is to be regretted that other such corporations cannot secure the bituminous fields."

At the morning session, Feb. 24, Henry G. Granger presented an elaborate paper, outlining a new plan for the construction of the Panama canal on sea level. Gustav H. Schwab also read a paper in favor of a sea-level canal. These papers elicited an extended discussion, the general tenor of which was in favor of a sea-level canal.

At the afternoon session, Prof. John D. Irving read a paper on the "Technical Education of the Mining Engineer."

He described the work at the Sheffield Scientific School and said that the course of school training for the mining engineer should be five years instead of four years, as at present. In the discussion following this paper, in which several well known educationalists participated, general agreement with the idea of Professor Irving was expressed. Prof. Louis D. Huntton followed with a paper on the "Hammond Metallurgical Laboratory at the Sheffield Scientific School," which was a description of the laboratory and an account of the development of the metallurgical course at Yale. After the reading of this paper the laboratory itself was visited by the members of the Institute. The members were also taken about the grounds of Yale University in automobiles, in spite of the severe rain storm which somewhat interfered with the plans for the meeting of this day.

At the evening session W. L. Saunders read a paper on "Driving Headings in Rock Tunnels." This was an extremely interesting and valuable contribution. Mr. Saunders stated in the first place with great frankness that the general factor in determining the speed and efficiency of driving tunnels is not the type of drill, but rather the way in which the drills are used. He stated and established conclusively that European methods of tunnel driving are superior to American, and pointed out the reasons why. Mr. Saunders was followed by D. Foster Hewitt, who, in an interesting paper, described the "Vanadium Deposits in Peru."

Upon adjournment of the evening session, at about 10 p.m., the members were invited to the Graduates' Club, where they were entertained with music, conversation and supper. This was a very pleasant courtesy on the part of the members of the club, which was warmly appreciated by the members of the institute.

At the morning session, Feb. 25, E. W. Parker read a paper contributed by J. E. Sheridan on the "Stag Cañon Fuel Company's Mines at Dawson, N. M." Joseph W. Roe then read a brief paper on the "Graphical Solution of Kutter's Formula."

In the afternoon the members visited the plants of the National Pipe Bending Company, the Bigelow Boiler Works and the New Haven Gas Company. In the evening there was a reception at Byers Memorial Hall. Friday and Saturday were devoted entirely to excursions, including visits to Bridgeport and Ansonia where several interesting industrial plants were examined.

The meeting was a highly successful one and the members departed with a feeling of keen appreciation of the hospitality extended by the citizens of New Haven and neighboring towns through the instrumentality of the very efficient local committee.

Views, Suggestions and Experiences of Readers

Comments on Questions Arising in Technical Practice and
Debatable Points Suggested by Articles in the Journal

CORRESPONDENCE AND DISCUSSION

Sampling by Machine

In some respects I agree entirely with the views T. R. Woodbridge has expressed in his letter on "Sampling by Machine" in the JOURNAL of Jan. 30. He shows at length that *mixing* a lot of ore composed of many sizes is not practicable. For that reason I have suggested that the end to be aimed at by feeding devices is *retardation*. Modern sampling is the art of taking a fair sample from a continuously moving stream of ore and the first cut made destroys that continuity. The 20-per cent. cut which goes on to a new sampling is followed by an 80-per cent. blank in the stream and it is essential to hold back the 20 per cent. and feed it to the next machine so slowly that its feed shall cover the whole time of the blank until a new cut joins the first. Vezin's cylinder is called a "mixer" and he thought that mixing was useful but I think he regarded its action as a retarding machine as much more useful than its mixing effect. His mixer and the whole class of shaking aprons and feeders are really continuously discharging storage vessels, while the intermittent form is seen in the fixed bin. And let us understand clearly that there is no theory that explains the use of these continuous feeders. They simply save manual labor. Probably the bin which is filled continuously and then discharged intermittently by the attention of a workman gives a more satisfactory service but it costs labor instead of power.

I find myself unable to agree with Mr. Woodbridge in another point he makes, that respecting the best number of cuts. He likens the ore to a ribbon 6 in. wide and 1000 ft. long and asks which would give the best results, taking every other 100 ft. or taking every other foot? As neither of these is done in practice, and the question as put is purely academic, we may go further and ask whether it is better to take every other 100 ft. or every other $\frac{1}{2}$ in. The question does not by any means provide an obvious answer. The true answer is that the number of cuts, and consequently their size, should vary with the coarseness of the ore, and we find this is actually the practice.

SAMPLING AN ART

He points out with entire correctness in other parts of his letter that sampling is one of the arts and is governed by cost and practicability. It must accept conditions as they are and not only make the best of them but do good work with them.

Otherwise it is not an art. This is done by submitting to whatever laws of nature we use in the process, guiding ourselves also by experience with such machines as we have. I have mentioned a mill where the fall from one machine to another was so great that the operation of gravity destroyed all possibility of good sampling. As to experience why do careful samplers look with doubt upon the practice of sending every 20th car or bucket of ore to the sampling mill? This is judgment matured by experience.

The literature of sampling reveals many divergencies of opinion but there are some conclusions that are rarely doubted. I was surprised therefore to read the discussion on selective action of scoops. The idea that the loss of one 2-in. piece of ore from the cut can be made up by throwing into it another 2-in. piece that ought to have gone into the reject is a fallacy which has been pointed out by Brunton, Vezin, and I think Argall, and no doubt by many others. All insist, and with truth, that a stream of ore does not have the same assay value in all its parts, that is to say that it cannot be counted on to have the same value either on its two edges, or in successive second intervals, or in different fragments of ore. It was on this ground that Brunton rejected his first sampler and pointed out that a double-oscillation machine cannot possibly take a fair sample. His second machine has a single crosscut followed by a rest (reject time) and then a new crosscut in the contrary direction and rest. Oscillation in the sense of a continuous cut from the beginning of the movement to the return of the gate to its first position is inherently fatal to correctness because it gives undue length of cut to one side of a heterogeneous stream. Mr. Woodbridge's dictum "the fact is, theoretically and actually, that A and D (of his illustrations) are balanced by B and C" is true only for approximate weight. It is not true for value. If it were true for value, a 5-per cent. cut would be as good as a 20-per cent. and all sampling machines would have nearly the same degree of correctness.

SIZE OF CUT AND CONDITION OF ORE

Another sentence in his letter, "I also think that it is the consensus of opinion that a rapidly moving machine takes a more accurate sample than the slower one," is undoubtedly true and I did not expect to have my doubts on this subject received with acclamation. The fact is

that all the gentlemen who have joined in this discussion seem to look at the subject from a point of view that is different from mine. In my thoughts I look constantly at the first cut with its coarse ore while the other correspondents of the JOURNAL seem to be thinking of the later cuts, on fine ore.

Comparisons unfavorable to sampling at mines and smelters have been made in favor of public, or custom sampling, but the published examples give no ground for believing that the custom sampler would do better work under the same circumstances. Give one of them 500 tons a day, the first cutting to be on 2½-in. ore and I do not believe there is one of them that would do better work than a good smelter sampler, unless especial attention were given to the work; and in all I have to say I am not talking about especial efforts. In such discussions the best work a mill has the right to show is the work done when the "boss" is not around.

The conditions at the two kinds of mills are so different that I do not think they can be compared properly. Take for instance Mr. Woodbridge's resampling of purchased lots. In one case nine lots averaged 6480 lb.; in the other, 13 lots averaged 3870 lb. The largest lot weighed 28,620 lb. and if this is taken out of the first series the average weight of the eight lots remaining is 3700 lb. Seven lots out of 22 weighed less than 2000 lb. We all know that this means close sorting and the average of 2.76 oz. gold per ton, in the 13-lot series also indicates it. Such lots represent 5 or 10 per cent. of the original ore and the gangue which has been thrown out would have been the most disturbing factor if the sampling had been done on the raw ore.

Then such lots are always crushed fine and all the errors incident to sampling a mixture that ranges from 2½ in. down to 0.01 in. are avoided. I presume the custom samplers do their work well but they have no reason to boast over what I may call *home* samplers. The two are simply not in the same class and cannot be compared.

MINE AND SMELTER SAMPLING

I think your readers will agree with me that sampling as a general art means principally sampling at mine, mill, or smelter and not custom sampling, which is merely one specialized branch of it, with the greatest difficulty that confronts the home sampler removed before the ore reaches the mill.

The last paragraph of Mr. Woodbridge's letter must be read between the lines. To ascribe, "the errors in sampling, or differences between samples and resamples," to, "faulty design or construction of the machine," can hardly mean Vezins made by the best shops in the country, and yet those machines have done bad work. It was for that reason that I have insisted that the true field for improvement lay in proper arrangement and system and not in the machine. Of the other causes of error cited I am interested to notice "neglect in repairing the cutting edges and keeping them to the designed shape." Mr. Brunton mentioned the same fault in a letter to the *Mining and Scientific Press* last year. I confess I have not been able to see the force of this reason. If a 10-per cent. scoop gets a blow that widens it to 11 per cent. or narrows it to 9 per cent., I do not see that the results can be affected. To me 18-, 20- and 22-per cent. cuts are all good, and practically *equally* good cuts. And so it is if an edge is worn down. It is worn for the gangue as well as for the "mineral" and though I do not advocate the use of worn out machines I cannot see how such an edge can discriminate.

"Loss of fines through leaks in spouts, etc." is not likely to keep the managers of Balaklala awake nights. Good work can be done in some home mills not only with, "lack of thorough cleaning between lots," but without one clean-up in a year! If a 10,000-ton lot of Trinity ore followed a 20,000-ton lot of Balaklala ore the best cleaning in the world would not make a difference of one mill per ton. But Mr. Woodbridge's explanations are reasonable for custom mills and show very well the great difference between the two kinds. These causes to which Mr. Woodbridge ascribes the errors in sampling are characteristic of the custom sampler and his point of view and we shall never agree in opinion because custom sampling, with its small lots of rich ore, is not what I am thinking or writing about.

None of your correspondents has shaken my belief that the most difficult part of the work in smelter sampling mills is the first cut when the ore is a mixture of sizes from 2- or 3-in. ring down to dust. If we postpone for the present the discussion of later cuts until the first one has been established properly I think it will be found that there is no consensus of opinion on size (and therefore frequency) of cuts. The whole body of information we have includes the later cuts on finer ore. Even when the coarse cut is mentioned the discussion is usually by a man whose experience has been mainly with fine ore only. Johnson is an exception because he was sampling for a furnace. The question of cutting a fair sample from such a mixture of very coarse and very fine is new in its present degree of importance be-

cause the building of mills at mine, mill and smelter is comparatively modern.

JOHN A. CHURCH.

New York, Feb. 13, 1909.

California Oil

In my general article on California mining published in the *JOURNAL* of Jan. 9, 1909, p. 122, the statement is made that all the oil companies of the State paid dividends of \$574,556 in 1908. This is of course an error, that sum being about one month's dividends. In fact, in the same number of the *JOURNAL*, on page 93, a list of dividends is given of those companies listed on the California Oil and Stock Exchange, and those of some not listed. The total dividends of the listed oil companies in December, 1908, were \$615,100, and up to that time these listed companies had paid an aggregate of dividends of \$18,008,882. In January, 1909, these companies paid \$405,638. It is not possible to get an exact statement of the dividends of all the oil companies operating in this State, many of the larger companies and some smaller private ones never making such matters public. The estimates of total dividends of California oil companies operating in California in 1908 run from \$4,000,000 to \$9,000,000, which shows a wide variance. However, the statement made by me in the *JOURNAL* of Jan. 9 was so much out of the way that even those not very familiar with the subject might have seen that it was an error, and a bad one at that.

C. G. YALE.

San Francisco, Cal.,

Feb. 20, 1908.

Mining Legislation at Washington

SPECIAL CORRESPONDENCE

Some action has been taken lately on several bills pending in Congress, and of interest to mining men.

MILL SITES

A report on the bill providing more liberally for mill sites has been filed by Mr. Bartlett, of Nevada, for the Committee on Mines and Mining, and it is expected that the bill will be passed either at the current or the special session of Congress. The committee notes that the bill amends section 2337 Revised Statutes by striking out all words in the section as it now stands which can be interpreted to require the non-mineral land to be non-contiguous or non-adjacent to the vein or lode, so it will read:

"Sec. 2337. Where non-mineral land is used or occupied by the proprietor of a vein or lode for mining or milling purposes, such land may be embraced and in-

cluded in an application for a patent for such vein or lode, and the same may be patented therewith, subject to the same preliminary requirements as to survey and notice as are applicable to veins or lodes; but no location hereafter made of such land shall exceed five acres, and payment for the same must be made at the same rate as fixed by this chapter for the superficies of the lode. The owner of a quartz mill or reduction works, not owning a mine in connection therewith, may also receive a patent for his mill site as provided in this section."

The section as now in force is construed by the department of the Interior to limit claims for mill sites to lands "not contiguous" to the vein or lode and "non-adjacent" to the surface ground embraced in the lode claim, and in practice the term "the vein or lode" is held to mean any vein or lode for which claim has been asserted whether or not the proprietary right is vested in the mill-site applicant. The amendment has been submitted to the Department of the Interior and has received its approval, as is evidenced by a letter from Hon. Frank Pierce, Acting Secretary of the Interior.

SURFACE RIGHTS OF ENTRYMEN

The House of Representatives on February 15, passed an Act for the protection of the surface rights of entrymen reading in part as follows: "That any person who has in good faith heretofore located, selected, or entered under the non-mineral lands laws of the United States any lands which subsequently are classified, claimed, or reported as being valuable for coal, may, if he shall so elect, and upon making satisfactory proof of compliance with the laws under which such lands are claimed, receive a patent therefor, which shall contain a reservation to the United States of all coal in said lands, and the right to prospect for, mine, and remove the same. The coal deposits in such lands shall be subject to disposal by the United States in accordance with the provisions of the coal-land laws in force at the time of such disposal, but no person shall enter upon said lands to prospect for, or mine and remove coal therefrom, without previous consent of the owner under such patent, except upon such conditions as to security for and payment of all damages to such owner caused thereby as may be determined by a court of competent jurisdiction. . . ."

The Senate in Washington is discussing in a desultory way the transfer of the Tennessee Coal, Iron and Railroad Company to the Steel Corporation, but no new facts have been brought out. It is rather remarkable that in this discussion there has been little or nothing said about the control of iron-ore supplies, which was a very important element in the transfer.

Reasons for the Commercial Depression—Berlin as a Gold Market

E. H. Holden, M.P., chairman of the London City and Midland bank, gave his stockholders the other day some interesting facts about the effects of the American panic of 1907 upon trade conditions in England and Germany. He said, among other things:

"The first backward movement from the prosperity of 1907 to the adversity of 1908 took place when the credit of American railroads was restricted. So long as they could obtain credit to carry out their extensions, so long were they able to give out orders to other industries, but when that credit was stopped, then the orders to other industries were stopped also. This, taken with a subsequent contraction of credit, caused a large fall in prices there, which, in turn, caused a fall in prices abroad. Just as we benefited from the increase of prices by the increase of our exports, so, in 1908, we have suffered from the fall in price by the decrease of our exports.

KINDS OF CREDIT

"There are two kinds of credit, one which is used for the purpose of carrying on commerce and industry and the other which is used for the purpose of holding securities. Experience has told us that these two kinds of credits cannot be maintained at a maximum at the same period, because there has not, up to now, been sufficient gold to support them. The year 1907 was a year in which the commercial credit was at its maximum, and the securities credit was at its minimum. The commercial credits have gone down with a shock, and the shock has been so sudden that it has thrown down the value of money in the principal countries of the world.

"The securities credits have not yet had time to increase so as to raise the value of money, but we see it is rapidly increasing. We are all hoping that trade will show some improvement, so as to create a demand for commercial credits, but we do not see much evidence of this at present, only, perhaps, to some extent in the case of the United States.

"The railways in the United States since the restrictions of 1907 have practically received all the money they have asked for. This has reacted on the other industries, and brought about a slightly improved trade. Does it not follow, then, that some demand must arise ere long, for the commodities, in respect to the large amount of loans which are being issued in this and other countries? It is in this direction we must look for improved trade and improved bankers profits.

EXTENT OF INDUSTRIAL DEPRESSION

"We in Great Britain are not alone in industrial depression. The commerce and industry of Germany received a great blow from the banking débâcle of last year in the United States. The effect of this blow has been manifest during the whole of 1908, and it has been quite evident that in Germany there was too much lending to undertakings which looked hopeful at their inception, but which have turned out otherwise in their realization, and it appears, in order to increase the liquid assets of their financial concerns, there has been gradual pressure kept on their industries. However, the financial position of Germany has changed for the better since the end of 1907, which has been brought about by its national bank granting greater facilities for importing gold. The Reichsbank has not only offered greater facilities for the import of gold from other countries, but also it has made a new departure in the case of South African gold, which, if persisted in and farther extended, may prove injurious to the South African gold market in London.

TAKING SOUTH AFRICAN GOLD

"Previous to last year, all South African gold was shipped to London for assay, sale, and transshipment to any countries requiring it, but during last year the ore from certain mines has been shipped direct to Germany, and there assayed. One cannot here refrain from examining the policy of the three great national banks during the last year—the Bank of England, the Reichsbank, and the Bank of France. From May 28 last to the end of the year the Bank of England rate was $\text{£}2\frac{1}{2}$ per cent. From Jan. 13, 1908, to the end of the year the Bank of France rate was $\text{£}3$ per cent. From June 18 to the end of the year the Reichsbank rate was $\text{£}4$ per cent. The result is an increase of gold in Germany of $\text{£}13,798,000$ and increase of gold in France of $\text{£}32,482,000$, and a decrease of gold in England of $\text{£}1,811,000$.

"Paris exchange on London has been so persistently low as to call forth all kinds of international explanations. We all know that the low exchange is due to the flow of credit to Paris, but the difficulty has been to explain correctly in what way this flow of credit has come about.

"During 1906 and 1907 the imports and exports of all countries were at their maximum. Paris took a great part in their financing, which she did through London and other centers, where of necessity she was compelled to maintain large balances. When we remember that in our own international trade we have had a contraction of about $\text{£}150,000,000$ of credit, and that other countries have also suffered, it follows that the contraction of the credit granted by the French banks must have experienced a large collapse,

thus rendering it a loss to maintain credit balances in other countries if the rate of interest were not higher than in her own country. Also France is playing a constantly increasing part in the issue of new loans, and it is reasonable to argue that some of these credits are being attracted home to take part in the new issues."

The Rare Metals IX—Vanadium

BY CHARLES BASKERVILLE*

Vanadium is classed among the rarer elements, but it is widely diffused in nature. It is most common in ferromagnesian rocks, yet traces of it are found in rocks of nearly every class. However, the definite vanadiferous minerals are not very numerous, as will be noted in the following list of vanadium minerals:

VANADIUM MINERALS.

	Vanadium Pentoxide Content.
Vanadinite, lead vanadate combined with lead chloride	8-12%
Endlicheite, arseniferous vanadinite	7-11%
Descloizite, lead and zinc vanadate	20-22%
Cuprodescloizite, lead, zinc and copper vanadate	17-23%
Roscoelite, a vanadium mica	20-29%
Carnotite, uranyl-potassium vanadate	19-20%
Ramite, a variety of cuprodescloizite	19%
Tritschelite, identical with cuprodescloizite	24%
Eusynchite, lead and zinc vanadate (descloizite)	17-24%
Dechenite, lead vanadate	45-49%
Volborthite, a hydrous vanadate of copper, barium and calcium	14%
Calciovolborthite, a hydrous vanadate of copper and calcium	37%
Brackebuschite, a vanadate of doubtful composition	24-25%
Psittacinite, a hydrous lead and copper vanadate	17-23%
Mottramite, a vanadate of lead and copper	18%
Chileite, an uncertain vanadate of lead and copper	13%
Vanadinite, a doubtful substance	44%
Vanadic ochre, vanadic oxide	100%
Lavrovite, a vanadiferous pyroxene	2%
Arennite, a vanadilo-silicate of aluminum and manganese	0 5-9.2%
Argyllite, a sulpho-vanadate of lead	
Eosite, lead vanado-molybdate	
Fritschelite, a mangan-uranite containing vanadium	22-27 3%
Vanadium-augite (lawrowite), a vanadiferous augite	2%
Vanadium-bronzie, a ferro-vanadiferous enstatite	
Vanadium-gummite, an altered uraninite containing vanadium	
Sulvanite, a double sulphide of copper and vanadium	

Vanadium and the vanadates are extracted from roscoelite, vanadinite, descloizite and carnotite. The most important use of vanadium is in its utilization as an alloying material for iron and steel; it increases the malleability and hardness of steel after tempering, and is consequently used in the production of sheet and tool steel, and armor plates. Other alloys containing vanadium, as vanadium bronze, have been found useful in the arts. Vanadium salts are used as mordants, especially in the printing of calico and in fixing aniline-black on silks; in the preparation of vanadium black; and in pre-

*Professor of chemistry, College of the City of New York.

paring an indelible ink. The oxides of vanadium have been used in ceramic decorating, and as autocatalysts.

The demand for vanadium is very strong and the prices high.

VANADINITE

This mineral occurs sparingly with wulfenite and pyromorphite near Sing Sing, N. Y.; with wulfenite and desclozite in Arizona and New Mexico; and with uranium minerals in sandstone in Rio Blanco county, Colorado. It is found sparingly in Montana, and also in Mexico. The only commercial deposits are in Arizona and New Mexico, where characteristic crystals are often found. Phosphorus and arsenic are sometimes present, both replacing vanadium.

Vanadinite occurs in small, sharp hexagonal prisms, sometimes cavernous, of deep ruby red, light brownish yellow, straw-yellow or reddish brown color. It is also found in rounded forms, in parallel groupings like pyromorphite, and in globular masses or incrustations. The luster is resinous on the surface of fracture, and the streak is white to a pale yellow. The hardness is 3, and the specific gravity is 6.66-7.23.

Vanadinite decrepitates in a closed tube, yielding a faint white sublimate. Before the blowpipe, it fuses on charcoal to a black lustrous mass, which in the reducing flame yields metallic lead and a yellow sublimate. After the lead is completely oxidized in the oxidizing flame, the black residue gives an emerald-green bead in the reducing flame with salt of phosphorus; this bead becomes light yellow in the oxidizing flame. With strong nitric acid the mineral becomes deep red, then yellow upon solution. When fused with three parts of potassium bisulphate, it forms a clear yellow mass, which reddens on cooling, finally becoming yellow when cold. Vanadinite is decomposed by hydrochloric acid. Chlorine may be detected in vanadinite by the following method: Oxide of copper is dissolved in salt of phosphorus on platinum wire with the oxidizing flame, until the glass is opaque; a small particle of the mineral is then placed on the bead, which is now treated with the tip of the blue flame. So long as chlorine remains, an intense azure-blue color is imparted to the flame surrounding the bead. This is caused by the volatilization of copper chloride.

Endlichite differs from vanadinite mainly by its lesser percentage in vanadium pentoxide and its higher content in arsenic pentoxide. It gives an arsenic odor on charcoal.

DESCLOZITE

This mineral is found in Sierra county, New Mexico, associated with vanadinite and iodyrite. It is also found with wulfenite in both New Mexico and Arizona. A variety is found in Beaver-

head county, Montana. Copper is sometimes present, and arsenic often replaces vanadium.

Desclozite occurs in small purplish red, brown or black crystals, forming drusy surfaces or crusts; in stalactitic aggregates, and also in massive, fibrous forms. It is a brittle mineral, transparent to nearly opaque, and possesses a greasy luster. The streak is orange to brownish red or yellowish gray. Its hardness is 3.5, and the specific gravity is 5.9-6.2.

When heated in a closed tube, desclozite gives water. On charcoal it fuses to a black mass, and is partially reduced to a globule of lead enveloped in a scoria. When fused with borax in a reducing flame it yields a green glass; with salt of phosphorus, it gives a glass of chrome-green color in the reducing flame, which assumes a yellowish orange color in the oxidizing flame. It is soluble in cold dilute nitric acid.

Cuprodesclozite contains copper in amounts which are often considerable. It also carries arsenic. It is usually found in crusts or reniform masses of a fine columnar structure, somewhat radiating. The color is dull green to greenish black, sometimes yellowish brown. Its specific gravity is 6.1-6.2.

The vanadium reactions are the same as in desclozite and vanadinite.

ROSCEOLITE

This mineral is the most important vanadium mineral. It occurs at Granite Creek, Eldora county, Cal., in the Magnolia district, Colorado, and associated with carnotite in Colorado. Its occurrence has been observed at Big Red Ravine, and at the Granite Creek locality, California.

Roscoelite is found in minute scales, and often in stellate or fan-shaped groups. The structure is micaceous. The color verges between dark clove-brown to greenish brown and dark brownish green, and the luster is pearly. Its specific gravity varies between 2.92-2.94. The mineral is soft, and is translucent.

It fuses easily to a black glass before the blowpipe, and gives a dark yellow bead with salt of phosphorus in the oxidizing flame; in the reducing flame this bead is emerald-green. Roscoelite is only slightly acted upon by acids.

CARNOTITE

This mineral is found as a canary-yellow impregnation in sandstone in western Colorado and eastern Utah. A vanadiferous silicate occurs along with carnotite; it is probably akin to roscoelite. In Utah the other vanadates, as calciovolborthite, are found. Carnotite occurs in Montrose county, Colorado, associated with malachite and azurite. It is easily separated by the fingers. Occurrences of carnotite have recently been described in Rio Blanco county, Colorado, and in western

Routt county, Colorado. In the latter deposit the carnotite appears to contain some arsenic; it is in the form of a film of powdery or amorphous material of a bright canary-yellow color.

Carnotite is distinguished by the chemical tests for uranium (article VIII in this series) and vanadium.

Geological Survey Appropriations

SPECIAL CORRESPONDENCE

A reaction in feeling on the part of House leaders is seen in the draft of the Sundry Civil bill reported to the House February 20, where appropriations for technologic work of the Geological Survey for fiscal years 1909 and 1910 are made. Comparison of the figures shows the following results:

	1909.	1910.	
		Recommended by Secretary of Interior.	Carried in Bill.
(1) For investigation of structural materials (products of the mine and the quarry) belonging to and for the use of the Government.....	\$100,000	\$150,000	\$70,000
(2) For the investigation of the fuel resources of the United States, with a view to greater efficiency in mining, treatment and use of these products.....	\$250,000	\$200,000	
(3) For investigation of mine explosions.....	150,000	150,000	100,000
Total.....	\$500,000	\$500,000	\$170,000

No increase in the total of the appropriations for this work was recommended by the director of the Geological Survey and the Secretary of the Interior; but a transfer of \$50,000 was recommended from the appropriation for the fuel investigations to the appropriation for structural materials, thus increasing the appropriation for structural materials to \$150,000, and decreasing the appropriation for fuel investigations to \$200,000.

The basis for this recommendation of transfer was the supposedly greater need for increased work and equipment in connection with the structural materials investigations, and an unwillingness at the present time to recommend an increase in the aggregate of the appropriations.

In the House draft of the pending bill no provision whatever was made for continuing the fuel investigations; the appropriation for structural materials was reduced to \$70,000, and the appropriation for mine explosions to \$100,000.

Personals

Mining and metallurgical engineers are invited to keep *THE ENGINEERING AND MINING JOURNAL* informed of their movements and appointments.

There is a vacancy on the editorial staff of the *JOURNAL* open to a young mining engineer, who should have had some literary experience. Candidates are requested to call in person.

James A. Macdonald has removed his office to 26 Exchange place, New York.

Reginald Meeks has returned to New York after a month spent in completing a mill at Quartzite, Arizona.

James McNaughton, general manager of the Calumet & Hecla, has been seriously ill at his home in Calumet, Michigan.

Horace V. Winchell, after having been for several months in Mexico and Florida, has now gone to Montana and California.

Whitman Symmes, San Francisco, has gone to Virginia City, Nev., where he will take charge temporarily of the Mexican mine.

John E. Rothwell, of Denver, Colo., is recovering from an operation for appendicitis, and hopes soon to be at work again.

J. W. Ponton has left Johannesburg in the Transvaal for a trip around the world, undertaken chiefly for the sake of his health.

G. A. Coenen has been appointed superintendent of the Walker Lake Gold Mining Company, with office at Sacramento, California.

Ernest Bamberger, manager of the Daly-West company, was in Denver, Colo., recently, attending the annual meeting of the company.

J. W. Evans, of Cobalt, Ont., has opened an office as mining engineer in the Lawlor building at King and Yonge streets, Toronto, Ontario.

S. E. Bretherton, of San Francisco, Cal., has been retained as consulting metallurgist by one of the large smelting companies in South America.

D. M. Ryan has resigned his position as superintendent of the Mexican, Sierra Nevada and Union Consolidated mines on the Comstock lode in Nevada.

Elton W. Walker, formerly at Tombstone, Arizona, has opened an office as consulting mining engineer in the Penobscot building at Detroit, Michigan.

J. Parke Channing has been chosen vice-president of the General Development Company, of New York. He has been consulting engineer of the company.

A. B. Neumann resigned his position as chief engineer of the Indiana Steel Company Feb. 1, and will take a few weeks' rest before engaging in a new line of work.

F. H. Moyer, formerly at the Clairton

works of the Carnegie Steel Company, has been appointed chief engineer at the plant of the Indiana Steel Company, Gary, Indiana.

E. J. Franz, consulting engineer and manager of the Indian Valley Mining Company, has returned to Plumas county, Cal., after a month's absence on professional business.

C. E. Stafford, of Pittsburg, formerly with the Shoenberger Steel Company, has been appointed engineer and general supervisor of the Prassinos Copper Company at Casa Grande, Arizona.

Walter Fitch, formerly superintendent of the Calumet & Hecla, has been chosen president and general manager of the recently organized Chief Consolidated Copper Company, and has taken charge of the property at Eureka, Utah.

Frederick Lewisohn has been elected president of the Tennessee Copper Company to succeed J. Parke Channing. James Phillips, Jr., succeeds Mr. Lewisohn as vice-president. Mr. Channing remains a director of the company.

Cortlandt E. Palmer, of New York, has tendered his resignation as officer, director and consulting engineer of the Esperanza Company to take effect on April 1, terminating six years of continuous connection with the property in charge of operations.

Cecil Morgan, of London, Eng., has returned to Colorado, and takes charge as manager of the Next President group of mines near Central City, owned by an English company. In the early days of Leadville and Idaho Springs, Mr. Morgan practiced his profession there, and left to take charge of the Broken Hill mine in Australia.

W. D. Ryan, National secretary-treasurer of the United Mine Workers of America, with headquarters in Indianapolis, has gone to Kansas City to take up his active duties as commissioner for the Southwestern Coal Operators' Association. Mr. Ryan's term of office does not expire until April 1, but the operators were desirous of having him enter upon his active duties as commissioner as soon as possible. He will be succeeded as secretary-treasurer of the Miners' union by Edwin Perry.

Obituary

Elias Johnson Baldwin, better known as "Lucky" Baldwin, died at Arcadia, Cal., March 1, aged 81 years. He was born in Ohio, but had been a well known figure on the Pacific Coast, whither he went in 1853. His reputation in recent years was chiefly as a sporting man. He was never actually a miner, though he did some prospecting in California and Nevada. In the early days of the Comstock Lode he was prominent as a speculator and at different times owned large interests in the Ophir and other mines

Charles Duncan, who died at Sparland, Ill., Feb. 18, aged 59 years, was born in Ireland, but came to the United States when a young man, after passing several years as a sailor. He worked at Braidwood and Streator for several years as a miner and mine foreman, and then went to Pittsburg, Kan., where he opened a coal mine and later had charge of it for several years. Some years ago he returned to Illinois as superintendent of the Devlin coal mines in and near Sparland, holding that position up to the time of his death.

Edwin Reynolds died at Milwaukee, Wis., Feb. 19, aged 79 years. He was born in Mansfield, Conn., and became a machinist. He was superintendent of various works, and finally of the Corliss Steam Engine Company at Providence, R. I. From those works he went to Milwaukee, to take charge of the shops of the E. P. Allis Company, now a part of the Allis-Chalmers Company. Here he introduced many notable improvements, chiefly in the design of blowing and pumping engines. His methods were at first considered revolutionary, but were later generally adopted. Some years ago he retired from active work, but remained with the Allis-Chalmers Company as consulting engineer.

Advices from the American Embassy at Buenos Aires, Argentina, state that Clement Rolla Glass, general manager of the Andes Tin Company in Bolivia, accidentally shot himself in that city Jan. 2 and died almost instantly. Mr. Glass was a native of Martinez, Cal., but had been in Bolivia and Peru for the past 10 years. He was educated at the University of California and at San Jose University. In the United States he held various positions of responsibility in the engineering department of the Southern Pacific and the Union Pacific railroad and was for a time deputy United States surveyor for the district of Nevada and in the United States Geological service. He spent considerable time in Alaska with mining companies and then went to South America where he spent about a year in exploring and then accepted the position of chief engineer of the Consolidated Copper Mines of Cerroco. Later he was manager of the Inca Rubber Company, of Peru; and at the time of his death was general manager of the Andes Tin Company, in Bolivia. He was a man of exceptional ability and did much toward placing the mining work of Bolivia upon a systematic basis. He was well known in South America and enjoyed a large circle of friends. He was 41 years of age.

Societies and Technical Schools

American Mining Congress—The executive committee has decided to hold the next annual meeting at Goldfield, Nevada.

Special Correspondence from Mining Centers

News of the Industry Reported by Special Representatives at San Francisco, Butte, Salt Lake City, Denver, Toronto and Johannesburg

REVIEWS OF IMPORTANT EVENTS

San Francisco

Feb. 24.—Some concerted action is planned against the dredging industry of California by certain cities and towns in the valley region. The residents of the valleys who are inimical to mining on general principles, are now attributing all the present flood conditions to the operations of the dredges, and have agitated the subject until the mayor of Sacramento has arranged for a committee to investigate the whole subject of gold mining by dredges. He very frankly states that he will place upon the committee only those persons who are opposed to dredge mining, and will not put anybody there who may favor this form of the gold-mining industry. The whole Sacramento valley is to be represented. Maps are being prepared showing all the gold-dredging districts in the valley.

The land owners at Biggs, Butte county, have held a meeting and the consensus of opinion was that dredge mining is the direct cause of the clogging of the Feather river, causing the overflows which have damaged farms, railroad bridges and towns. The dredgers complained of are those at Oroville. There is an evident desire to put a stop entirely to the system of dredge mining.

Although the bill which creates the office of mine inspector for the State of California passed the assembly with very few dissenting votes, it has since been more carefully considered by the Senate committee, and it is not very probable that it will become a law. The passing of the act would have created a new office for which there is no demand from mine owners or superintendents, and given a chance for disgruntled employees to "get even" with the owners of the mines. The bill which is known as the employers' liability bill is not at all likely to become a law. It was vigorously opposed by the mine owners of the State.

Yuba county has a county ordinance against hauling wagons with loads over 3200 lb. on the county roads during the wet season. This may have been all right before the advent of the large dredging and machine-shop enterprises in Yuba, but it is working a hardship at present. Indeed, the manufacturers of dredge machinery at Marysville and the operators of dredges at Marigold and Hanmonston cannot readily carry on business if this ordinance be enforced. Some of the wagons of these companies weigh up to the prescribed limit even without any loads. There are now at Marysville some

250,000 lb. destined for the dredges 10 miles distant, which cannot be moved by wagon. The companies have been forced to adopt the use of old-fashioned sleds and with big teams are now hauling freight over the mud. There are 12 dredges operating in the district and the largest company is making a test case as to the legality of the ordinance.

The settlement by compromise of the legal troubles between the Pacific Power Company and the Northern California Power Company which related to water rights and a power site, is good news for Shasta county. The Northern cannot now be impeded in developing its 14,000-h.p. plant.

The State legislature has made an appropriation of \$400,000, and the governor has signed the bill for dredging the Sacramento, San Joaquin and Feather rivers as recommended in the special report of the California Débris Commission. The measure does not go into effect until Congress appropriates an equal sum for the same purpose. The California delegation in Congress has appeared before the Congressional committee in favor of this particular measure.

The Rutherford bill appointing a State mine inspector has passed the assembly of the legislature by a large majority notwithstanding the fact that the California Miners' Association reports unfavorably. Indeed, before the association had called the attention of the members of the legislature to the bad features the Assembly had taken action. The Senate has yet to pass on the bill. The author of the measure, Mr. Rutherford, has received many congratulatory letters from the miners' union and individual miners, but it is not to be noted that he received any from mine owners or superintendents. In fact, the mine owners are all opposed to the measure. Another measure which has also passed the Assembly is one which may be of service, as it provides a way by which the administrator of an estate of deceased or incompetent persons may bond a mine as well as sell it. Under present laws a mine may be sold, but there is no provision by which a bond may be granted upon it. The passage of this bill will facilitate matters in several estates in process of settlement now.

It is not thought that the very obnoxious measures called the employers' liability bill, where the negligence of a fellow servant shall not be a defense in case of injury, will pass the legislature. This and the proposed eight hour law for under-

ground miners would have the effect of closing down a number of mines which are being now worked without profit. All such bills are considered by the mine owners and superintendents as labor-union bills. While the labor unions have a strong "pull" in the legislature, it is supposed that sober judgment will prevent the passage of such measures as are very much opposed by the owners of mining properties. If too much unfavorable legislation occurs numbers of mines will close down for good.

The rain storms continue all over the State and considerable snow is falling in the mountains. The gravel miners are utilizing the full streams, but the quartz miners are having more water than they care to handle and a number of mines have quit work. Considerable placer mining on a small scale is being carried on in all the ravines where water is now plentiful.

A postponed hearing is to be held on March 3 in the contested mineral land patent case of Harold T. Power, of Bullion, Placer county, who is endeavoring to patent certain drift mining ground in that county for the California-Nevada Consolidated Placer Company. The Forest Service has remonstrated against the issue of a patent to Power on the ground that the land is more valuable for timber than for mining and that he has not lived up to the law in the matter of improvement. Power traced this channel up by the rim from the side of the Hidden Treasure mine and has held it by possessory title for ten years or more. When he finally got capital interested to open the mine and asked for a patent the Forest Service officials said he wanted it for timber, not for mining, and that he could not show paying gravel. As he had not yet run his bedrock tunnel and there were some hundreds of feet of lava overcapping the channel, of course he could not show pay gravel except at one blowout. He took the rangers through his big drift mine and showed them how that was worked and how it was not possible to get out gravel until a tunnel was run; but they persisted the timber was worth more than the lava capping showed.

A. F. Ross has ended certain litigation involving valuable copper ground in Shasta county by giving a deed to Mrs. Ellen M. Rose, the heir of J. H. Stowall. That gentleman before his death gave a bond to Ross and as long as this bond stood the claims could not be sold. It is understood that the Balaklala Copper

Company, operating at Coram, may now buy the claims.

The mine owners and superintendents of California are objecting to two proposed measures pending before the legislature. One of these is that which provides for a State mine inspector, and the other is one relating to the liabilities of employers in and around underground mines, smelters, concentrators, coal washers, mills, factories, and workshops. The main and objectionable feature of this latter bill is that it provides that, in actions for damages for personal injuries by an employee, the fact that the injuries were due to the negligence of a fellow servant shall not be a defense. Neither shall contributory negligence be a defense, unless it be through reckless or grossly careless exposure to unnecessary danger. Under this law a written contract to the contrary would not be legal or binding.

Hornbeck, McQuistin & Cox are experimenting on the Sacramento river below Redding with a mining machine which has a tube or caisson lowered from a hull or boat to the bed of the river. The tube is 5 ft. in diameter, and material at the bottom is shoveled into buckets and hoisted. One of these machines is to be tried at the Nome beach the coming season, and it is reported that five more are contracted for.

The old Easy Bird mine, near Mokelumne Hill, Calaveras county, has been placed under bond to Joseph King and Mr. Mandigo, of Seattle. There is a 10-stamp mill at the mine which will now be replaced with one of 40 stamps. The ore in this property carries a large proportion of sulphurets. The full extent of the ground will now be determined as extensive operations are to be commenced at once.

Salt Lake City

Feb. 26—The development work in the Mascotte tunnel is showing up a large deposit of copper-bearing porphyry in the property of the Ohio Copper Company. The shaft and upraise are now about 130 ft. apart, and connections should be made within two weeks.

Six feet of steel galena and 2 ft. of lower-grade ore were struck in an upraise from the 250 in the Butler-Liberal at Bingham. Assays give 62 per cent. lead and 20 oz. silver. The Butler-Liberal is controlled by the North Utah Mining Company, an English corporation.

The Utah Copper Company has declared its regular quarterly dividend of 50c. per share, 725,590 shares being issued.

The blower for the copper furnace at the Knight smelter has arrived, and as soon as it is installed the copper furnace will be started on ore from the Grand Central and Victoria. The three lead furnaces are smelting 750 tons of ore per day.

The shaft at the Centennial Eureka is down 2200 ft., and three shifts are at work deepening it.

The Little Chief Consolidated Mining Company has been formed by Michigan capitalists, with a capital of \$1,000,000. Walter Fitch is president; F. W. Denten, vice-president; W. P. Seager, secretary and treasurer. M. M. Duncan, A. B. Meyer, J. H. Rice and J. R. Van Evera are directors. The holdings of the company comprise eight claims in the Tintic district, embracing the property of the Van Evera Company, and the control of the Little Chief. The Little Chief shaft is down 1400 ft., and the group will be worked through it. Mr. Fitch will manage the property.

The Cactus mill will be overhauled and remodeled by A. J. Bettles, the Newhouse mill expert. Half of the mill has been closed down and the other half will continue in operation until the required changes have been made, which should be early in April. This half will then be closed down and remodeled. The capacity will be increased to about 1200 tons per day.

Edward Fink with Howard P. Saunders has been effecting changes and improvements at the Garfield experimental plant for the Fink furnace. Within a short time a run will be made on copper ore from the Cactus mine.

For the week ending Feb. 19, the following Tintic mines shipped 20-ton carloads: Dragon Iron, 41; Colorado, 30; Brooklyn, 7; Beck Tunnel, 3; Swansea, 1. The following mines shipped in 50-ton carloads: Ajax, 1; Centennial Eureka, 40; Sioux Consolidated, 10; Iron Blossom, 1; May Day, 12; Yankee, 4; Eagle & Blue Bell, 1; Bullion Beck, 1.

Butte

Feb. 25—In accordance with its plans for using electrical power over the division of its road between St. Regis, Mont., and St. Joe, Idaho, the Chicago, Milwaukee & Puget Sound Railway Company has let contracts for the construction of two power plants to supply 30,000 h.p. One will be located at St. Joe, Idaho, and the other at a point on the Missoula river about 40 miles below Missoula, Mont. The South Butte Mining Company has instituted action on a judgment secured against the Butte Central Copper Company in the Federal circuit court last year. The several directors of the last named company are made defendants in the new action under the law making directors of corporations liable for all corporate debts when the corporation fails to file its annual statement. Notice has been given that the annual meeting of stockholders of the Barnes-King Development Company will be held at Kendall, Mont., on March 3.

In the case of Hugh Magone against the Colusa Smelting and Mining Company, the Parrot Silver and Copper Com-

pany, the Colusa-Parrot Mining and Smelting Company, the Butte & Boston Consolidated Mining Company, the Anaconda Copper Mining Company and the Montana Ore Purchasing Company, Judge Hunt of the Federal circuit court has recently adopted the findings of Master-in-Chancery Crane except insofar as they are adverse to the Anaconda company. The suit was brought as a test case to determine the liability of the companies for damages alleged to have been sustained by farmers along Silver Bow creek because of the pollution of the water by the smelters operated by the several companies. The master-in-chancery found complainants damages to be \$1500 and divided it equally among the several defendants, but the judge found only nominal damages against the Anaconda company and apportioned the total amount equally among the other companies. Questions of law upon the findings will be argued on April 13 at Butte.

Denver

Feb. 27—Since last week the mining camps of Colorado have been in the grasp of a blizzard and its after effects, blocking railroads, causing snowslides, and hindering operations generally.

In the Cripple Creek district, the first bimonthly dividend of the year to Elkton stockholders, have been paid, amounting to \$37,000, making a total of about \$2,280,000 paid to date. The deep-drainage tunnel has reached a distance from the portal of 3025 ft. The mill built by the Isabella, below the dump at the mine, is turning out bullion, and the result of the last 30 days' run is a gold brick worth \$6500.

Toronto

Feb. 25—Several more fines have been imposed on mining-company promoters for violation of the Ontario Companies' Act, in issuing prospectuses not containing the information required by the law. D. K. Martin, president of the Aganico Mines Development Company, who pleaded guilty on two charges was fined \$200 on the first charge and \$100 on the second with costs in each case. E. D'Aguiar, of the Moose Horn Mines Company, and J. W. Garvin, of the Titan Montreal River Cobalt Development Company, paid \$200 and costs each, the cases being settled out of court.

Sir William Meredith, chief justice, has delivered an elaborate judgment in test cases submitted to him to ascertain the meaning of the clauses of the act relating to prospectuses, clearing up some doubtful points. He ruled that the filing and issuing of one prospectus complying with the terms of the act, was not sufficient to justify the issue of subsequent ad-

vertisements or prospectuses offering stock for sale not containing the information required, and that on every occasion on which a company issued a prospectus inviting the public to take stock or lend money. Such prospectus must be filed with the Government and must contain the specified information.

A new provincial mining division, to be known as the Gowganda Mining Division, has been created, consisting of territory detached from the Montreal River and Temagami Forest-reserve divisions and including the townships of Gamble, Brewster, Corkill, Lawson and Chown. The head office will be temporarily located at Smyth (Elk City) but will later be removed to the Gowganda town plot now being laid out at the foot of Gowganda lake. Henry Sheppard, of Orillia, has been appointed mining recorder.

A great deal of wildcat prospecting has been going on in the Gowganda district all winter. Large areas covered with snow have been staked when discovery was impossible in the hope of making discoveries later. In many cases these claims have been sold to speculators or promoters, so that the frequent difficulties as regards title which characterized the early development of the Cobalt camp are likely to be repeated.

Machinery and supplies are being hurriedly rushed forward to Gowganda, while the sleighing lasts, as with the opening of spring, it will be a difficult and expensive matter to bring in heavy freight.

A delegation headed by Thomas Cantley, general manager of the Nova Scotia Steel and Coal Company and A. Dick, general sales agent of the Dominion Coal Company, representing the leading coal-mine owners of Nova Scotia, interviewed Hon. W. S. Fielding, Canadian Minister of Finance at Halifax on Feb. 15 urging the re-imposition of a duty on American anthracite. They represented that there had been a falling off in shipments of Nova Scotia coal to Quebec province, caused by the importations of the cheaper grades of American coal. It was also asserted that the tariff was evaded by the importation of slack coal of a larger size than 34-in. screen. Small sizes of anthracite, it was claimed, were replacing the Nova Scotia coal. Both English and American coal were being dumped in Canada at lower prices than those charged in the home market. Mr. Fielding made a non-committal reply, and in view of the record of the present government on tariff questions, it is not regarded as at all probable that any duty will be placed on anthracite.

Johannesburg

Feb. 2.—Big electric-power schemes have long been under discussion upon the Rand, and the erection last year of cen-

tral generating stations by the Victoria Falls Power Company enabled several companies starting up new mills in the East Rand to effect heavy economies in capital expenditure. But how far or how speedily this pioneer work of power distribution would lead to the "electrification of the Rand" has been a speculative question, owing to a complication of financial interests, until the publication of important announcements the other day. Contracts secured by W. A. Harper to supply power to the Wernher-Beit mines have been taken over by the Victoria Falls Company, a title which must appear misleading now that all thoughts of supplying the Rand with power from the Zambesi river have been abandoned, so that in two years fully a third of the Rand's tonnage will be drawn from mines operated with electric power. Existing steam plants will be maintained as reserves until the reliability of the scheme is safely established. The contracts, upon the strength of which it has been possible to arrange for the erection of a great central station, provide for the initial distribution of 270,000,000 units per annum, but it is hoped that it will be possible to double or treble the call in the near future. The new station to be erected will have a capacity of 90,000 kilowatts.

The importance of the scheme is increased by the further provision made for the installation of at least three central compressed-air generating stations, supplying air at 100 lb. pressure. No companies will profit from these innovations more substantially than those which are now in the developing or early producing stage, and have not yet put up large steam-driven reduction plants. But it is estimated that centralization of power will result in a reduction of about 8d. per ton milled in power costs upon the Wernher-Beit group, apart from a consideration of the certain economy due to the accurate metering of supplies.

The mineral output of the Transvaal for 1908 has been declared by the Government Mining Department at a value of £32,657,088, or £1,930,183 in advance of the previous year's total. Decreases and increases for each class of production may be tabulated as follows:

	1908. Yield.	Changes.
Gold	£29,980,526 l.	£2,579,534
Diamonds	1,549,815 D.	718,260
Coal	794,949 l.	21,300
Base metals, etc.	246,766 l.	54,470
Silver in gold bullion	83,032 D.	6,861
Total	£32,657,088 l.	£1,930,183

The annual meeting of the Premier Diamond Mining Company is to be held in Johannesburg Feb. 23, and the public awaits with interest the chairman's justification of the board's policy of maintaining a high rate of production in the face

of prevailing market conditions. Not only must he explain the recent maintenance of the producing rate in excess of possible sales, but also the preparations in process for the speedy duplication of yield. To some extent, the directors' line of argument has been previously indicated by the publication of an annual report, in which their apparent opposition to any scheme of coöperative output regulation in conjunction with De Beers is explained by the expression of opinion that measures for the maintenance of an effective monopoly are only practicable under circumstances, allowing all producers to work in a fair ratio to their capacity and when the demand for diamonds extends to all qualities. It is reassuring to note that the directors declare their steadfast intention not to increase sales by lowering prices, and to hold in reserve the growing accumulations of stones of classes for which there is no demand. Still the fact remains that the diamonds of Premier mine quality have seen a marked depreciation in value, while those from Kimberley and Jagersfontein, owing to the keenly restrictive policy adopted, have held a steady price.

A series of exceptionally heavy rains throughout the Transvaal, lasting for several days, has resulted in much damage to mining properties on the Rand and in the outside districts. On Jan. 21, over 7 in. fell at Johannesburg, and this abnormal downpour was attended by considerable loss of life. The most serious sequence of the floods was the bursting of the May Consolidated dam, the water from which poured down a shaft of the Witwatersrand company and speedily filled the mine with water. There were 160 at work below, and they were at first believed to have been drowned, and after a few days of vigorous pumping and exploration almost all hope was abandoned. On Jan. 28, however, the unrelaxing efforts of the management were rewarded by the recovery of 25 natives, who had taken refuge at the top of a back stoep, to which the water had not risen, owing to air pressure. Kafirs are well known to be endowed with great physical endurance, but it has been a cause of marvel to all that these "boys," entombed for seven days without food, should have been found, not only alive, but in several cases still in a condition of full consciousness and fair strength. Two of the natives met their rescuers by swimming many yards along the drive and nearly all recovered sufficiently, after a few hours' medical attention, to wish to return to the mine compound. Such wonderful fortune, displayed by an average batch, provides unique testimony, not only to the natural capabilities of Rand unskilled workers, but also to suitability of the conditions under which they live upon the mines.

Mining News from All Parts of the World

New Enterprises, Installations of New Machinery, Development of Mines and Transfers of Property Reported by Special Correspondents

THE CURRENT HISTORY OF MINING

California

BUTTE COUNTY

Fall River Section—In the Mooretown ridge there is much activity, and several mines are under process of development. One of the quartz mines will soon be equipped with a mill.

CALAVERAS COUNTY

Black Metal—This property, owned by San Andreas men, is yielding handsome quartz specimens, in addition to the "black metal" obtained.

Mauna—This mine at Jesus Maria has been bonded to men who will develop it.

EL DORADO COUNTY

Church Gold Mining Company—This company has sold to Seymour Hill the Golden Fleece claim in El Dorado district and the El Dorado claim in Mud Springs district, together with the 10-stamp mill, hoist, and other machinery.

Loveless—The claim near El Dorado, owned by the Lawless Brothers, which has been worked as a pocket claim, has been bonded to men from Missouri.

FRESNO COUNTY

Arkansaw—G. W. Bruce has sold his interests in this mine at Trimmer to R. Sides, of Selma. The ore now being mined is quite satisfactory to the owners.

INYO COUNTY

Chrysopolis—This old camp is again attracting attention owing to the strike in the ground of Black, Stewart & Lochrie, where they have found high-grade ore. These men own nine full claims.

Four Metals Mines Company—The mines at Cerro Gordo are temporarily closed awaiting improvement of water supply. The springs from which the supply is drawn are low.

MARIPOSA COUNTY

Hotaling—This claim in Indian Gulch, with 12 men at work, has recently encountered a good body of ore. There is a five-stamp mill on the property.

Mariposa Commercial and Mining Company—The power plant of this company has had to close down, stopping all the mills of the company in the county. The high water has endangered the Bagby dam.

MODOC COUNTY

Mountain View—The grade of ore being taken out of this mine in Hoag dis-

trict is very high. Preparations are being made to erect a 40-stamp mill.

NEVADA COUNTY

California-Montana—It is intended to resume operations on this mine, Nevada City district, and a new Sullivan compressor has been put in and set at work.

Coan—At this mine, Nevada City district, Thos. Coan owner, high-grade quartz is being mined. There is a four-stamp mill on the property.

PLUMAS COUNTY

Crescent Hill—This company has been formed by Wilmington, Del., men including S. N. Shive, S. E. Robertson and H. W. Davis, to work the Crescent Hill mine south of Quincy and on the northern slope of the Middle fork of Feather river.

SAN DIEGO COUNTY

Two Flags Mining and Leasing Company—This company has been organized under Wyoming laws to work certain claims in Dulzura district. Among the directors are A. J. Elliott, Edmund Meyer and E. Strahman, of San Diego.

Colorado

LAKE COUNTY—LEADVILLE

Catawba—Considerable work has been done on this property, Prospect mountain, during the last year, and a number of pockets of ore high in gold, have been found, but so far the main ore horizon has not been cut. A drift is being carried east, about 60 ft. from the incline, and will cut through the flint wall under which it is believed the main orebody will be found.

Dinero Tunnel—Prospecting has been carried on in the orebody opened at the breast of the tunnel and some high-grade ore has been found that is now being sent to the smelter. In the body of ore recent work has opened veins of high grade, several feet in thickness, within the main ore shoot. In addition to this the old Dinero vein has been caught in the upraise and ore from this is also being shipped to the smelter. Recently ore bins have been erected at the mouth of the tunnel and are now nearly full, as of late it has been impossible to ship ore on account of the heavy snow storms.

Iber Mining Company—Lessees working at the 1,300-ft level of the Little Jonny recently opened a body of ore 12 ft. high,

carrying gold, and fair quantities of silver, copper and lead. Before this body opened work was being done on a 4-ft. fissure vein. The depth and breadth of the shoot have not been ascertained yet. Other lessees on the property are shipping steadily, and the output from the mine reaches 7500 tons per month.

Lime—Two tunnels are being driven on this property, Iron hill, owned by the Iron Silver Company, by lessees, one above the California gulch road and the lower from the bottom of California gulch, into Iron hill. The upper tunnel is in 250 ft. and has opened a good body of iron from which shipments are going out steadily. The lower tunnel will drain the hill and cut the present oreshoot 200 ft. deeper.

Valley Shaft—This property, South Evans gulch, is averaging a daily output of 60 tons of an excellent grade of lead sulphide. While development work was being carried on recently in one of the lower levels another body of ore was cut.

OURAY COUNTY

Camp Bird—The London office reports that during January the mill ran 28 days, crushing 6502 dry tons of ore. The product was 11,637 oz. bullion and 554 tons concentrates. Sales of bullion and concentrates produced \$226,088. Mine expenses were \$51,257 and London expenses \$1500, leaving a net balance of \$173,331. Payments for construction were \$453; development work, 734 ft during the month.

SAN JUAN COUNTY

Gold King—A large quantity of concentrates is piled up at this mine at Gladstone. Efforts are being made to clear the road from snow.

Hercules Consolidated—At the Little Dora, near Silverton, the mill is treating 60 to 70 tons of crude ore daily. A new boiler and a large air compressor are the latest additions to the equipment.

SUMMIT COUNTY

Wellington Mines Company—A contract has been closed, under which the Central Colorado Power Company will deliver 100 h.p. electric to the Wellington mill at Breckenridge, beginning March 1. The new mill is expected to be ready for work early in March. The capacity of its crusher is 200 tons per day, and it has three sets of rolls, with several screens. It has 58-ft bucket elevators, and three jigs of 12 compartments each. The latter are twice as large as any now in use.

in the Breckenridge district. There are four tables and two motors. The building is electric lighted and steam heated, there being a separate building for the generation of the steam.

TELLER COUNTY—CRIPPLE CREEK

El Paso—Formal notice has been served on all lessees on El Paso mine on Beacon hill that their leases will not be extended beyond May 1 next. No statement of the company's plans will be made until the annual meeting on March 8, but it is supposed that the mine will be operated directly.

Henry Adney—High smelter returns have been received from recent shipments of ore made from a rich streak found next the footwall of the vein.

Hiawatha—At the annual meeting, to be held April 7, notice is given that the stockholders will be asked to decide whether the company will operate the mine, or whether proposals to buy or lease it shall be accepted.

Mohican—The Western Investment Company of Victor has taken over the lease formerly held by the Chief Mining and Development Company on the Mohican, on Battle mountain, owned by the Mohican Gold Mining Company. The original lease was for three years and has two years to run. The shaft on the Mohican has been connected with the 100-ft. level on the Ajax main shaft, and shipping ore has been developed at this depth.

Indiana

CLAY COUNTY

Vandalia Coal Mining Company—A mortgage on this company's property to the Union Trust Company, of Pittsburg, has been recorded. It is to cover an issue of \$1,000,000 in 25-year bonds, the proceeds to be used in developing and opening new mines.

SULLIVAN COUNTY

Hudson Coal and Mining Company—The suits against this company have been settled by the payment of \$31,000 debt, and the application for a receiver has been dismissed.

Louisiana

Petroleum production in January is reported at 22,800 bbl. Only three new wells were completed, of which two produced gas and one was dry.

Michigan

COPPER

Calumet & Hecla—It is announced that all differences between this company and A. S. Bigelow have been adjusted, and that details have been arranged for the transfer of all the Bigelow or "Sears

Building" holdings in the Osceola, Tamarack, Ahmeek, Seneca, Isle Royale and Laurium properties to the Calumet & Hecla Company, the number of shares involved being, it is stated, about 125,000, and the amount involved approximately \$8,000,000. All litigation by Mr. Bigelow against the Calumet & Hecla will be withdrawn, the injunction restraining the voting of the 22,671 shares of Osceola stock formerly owned will be dissolved and the annual meeting of that company will take place early next month, when the Calumet Company will elect its board under proxies recently solicited and assume the management.

The Calumet & Hecla Company has sold to Lee, Higginson & Company, of Boston, \$950,000 in three-year, 5-per cent. notes, and \$1,000,000 in 10-year, 5-per cent. notes; the 10-year notes can be called in at par any time after three years. It is stated that the firm has re-sold the entire amount to investors.

Seneca—This company has encountered the Kearsarge lode in the crosscut from the first level of its shaft, and has exposed encouraging mineralization. Sinking has been resumed in the shaft at a depth of 250 ft. This shaft is in the footwall about 75 ft. behind the lode. It is equipped with machinery for a 2000-ft. depth.

Adventure—An inclined diamond-drill hole is going down near the proposed site of the new shaft to further check the data obtained from previous drilling. Three copper-bearing lodes have been penetrated, the drill cores in each showing good mineralization.

Atlantic—The crosscut from the 20th level of Section 16 shaft has entered an amygdaloid foundation carrying copper in epidote. Sinking continues in the shaft.

Franklin—This company is opening good ground at the 23d level on the Pewabic lode. Securing the Rhode Island property through stock ownership gives the company about 12,000 ft. on this lode. The shaft on the Rhode Island tract is down about 1300 ft. without showing copper-bearing ground.

Grotiot—This subsidiary company of the Calumet & Hecla is sinking two shafts on the Kearsarge lode. No. 1 is down below the eighth level and No. 2 below the 10th. Drifts are being extended. The company is at present without railroad facilities, but this will in all probability be provided the coming summer when a mill run will be made at one of the Calumet & Hecla mills.

LaSalle—This company, under the management of the Calumet & Hecla, is being opened on an extensive scale. Sinking is in progress in both shafts on the Caldwell lands. While the Tecumseh shaft is temporarily bottomed below the 17th level, drifting is going on both

north and south at all levels below the ninth, and large quantities of ground are being blocked out. The Kearsarge lode at this point averages about 10 ft. thick. At No. 1 shaft of the Caldwell, which is down below 750 ft., a crosscut is being extended both east and west.

Montana

MONTANA—BUTTE DISTRICT

Butte & Balaklava—This property is now undergoing examination by F. H. Probert, a well known mining engineer. It is reported that the examination is being made for the Boston Stock Exchange with a view to listing the stock on the exchange.

Butte & Superior—The shaft has reached a depth of over 1400 ft. and a station has been cut on that level. From there a crosscut has been started to the vein which is supposed to be about 100 ft. distant.

Tuolumne—The shaft has reached a depth of 1300 feet.

North Butte Extension Development Company—Since the reorganization about \$130,000 has been paid on debts and options on claims. Another payment is due April 1.

Davis-Daly—Payments on the company's options have been extended to April 1. It is expected that by that time the company will have received all of its stock assessments and will be able to meet payments and have a substantial balance left in the treasury for development work. The work is at present being concentrated on the Colorado shaft, which is being enlarged to three-compartments. Operating expenses do not exceed \$15,000 monthly.

Nevada

ESMERALDA COUNTY—GOLDFIELD

Yellow Tiger—Three shifts are engaged in sinking the main shaft from the 600-ft. to the 1000-ft. level. Laterals will be run at 100-ft. intervals in search of the ore-body already opened on 600-ft. level.

Moore Lease—A strike has been made in the 500-ft. level of this lease on the south end of Combination No. 2 lode of the Goldfield Consolidated property. As says across the ledge return from \$15 to \$170 per ton, and a streak 2 in. wide shows from \$150 to \$200.

Gottwaldt Lease—As a result of the strike in the Moore lease, work will be resumed on this property, which lies directly east. A great amount of exploration work has already been performed and though small stringers carrying good value have been found, ore in sufficient quantities for shipping has never been encountered.

Kewanas—The crosscut driven from the

450-ft. level to cut the oreshoot followed in the old incline shaft, is now in 300 ft., and it is expected that the vein will be intercepted soon for the indications of mineralization are better with every foot gained.

Goldfield Daisy—Small shipments, averaging two wagonloads a day are made from this property to the Nevada Goldfield Reduction Company; the output is curtailed by a large flow of water and heavy ground.

St. Ives Lease—Two small lots were shipped from this property Feb. 18, one of five tons returning \$338 per ton, and six tons \$59 per ton, the ore coming from the 100-ft. level. The company recently acquired six claims in the Walker River range which will be made a part of the Leasing Company's holdings. Little work has been done, though surface assays give from \$8 to \$35 per ton, gold, silver and lead.

Consolidated Red Top Lease—A carload shipment was made from this property on Feb. 16. Both raises, started recently, from the 300-ft. level are in ore, as is the crosscut, which has been advanced to the south to intercept the orebody pitching in that direction.

Little Florence Lease—The 75-h.p. double-drum electric hoist, and the 15-drill compressor are now both in commission; 22 men are employed on the lease and in prospecting. On the 357-ft. level, the big ledge, 37 ft. wide, recently encountered is being drifted upon to the east. On the 500-ft. level a raise has been started on a stringer, which though only 4 in. wide returns favorable assays.

Burns Lease—This lease was recently granted on a tract with a shaft already 200 ft. deep. A gasoline hoist has been installed and extensive development work will be done.

Commonwealth—The Wilbur lease on this property is doing considerable work on the 100- and 300-ft. levels; several small shipments were made from the tunnel level, and the crosscutting now carried on is for the purpose of locating the orebody at depth.

ESMERALDA COUNTY—HORNSILVER

Orleans—Two shipments from this property of 10 and 22 tons to the Nevada Goldfield Reduction Company returned \$127 and \$65 per ton respectively, chiefly gold with a small amount of silver.

NVE COUNTY—TONOPAH

Montana-Tonopah—The east and west drifts on the 515-ft. level of the Martha vein were advanced 32 ft. during the week. In the face of the west drift 1 ft. of fair milling ore is exposed, and the east drift shows 2 ft. of a higher grade. The raise on the Triangle vein was carried up 20 ft. during the week and shows 5 ft. of good milling ore. Stopping

is carried on from all the levels, and 210 ft. of ground was broken during the week. The mill treated 780 tons from the mine and 250 tons from the MacNamara with an average extraction of 89 per cent. The furnaces in the refinery plant are now completed and will treat the next cleanup of cyanide precipitates.

MacNamara—Six feet of milling ore is exposed in the face of the east drift from the south crosscut, 200-ft. level, which is being sent to the mill. In the east drift from No. 5 stope at 40 ft. above the 200-ft. level, 6 ft. of low-grade quartz has been exposed; this drift will be continued and connection made with the 150-ft. level near the west line of the property. The stope from the 300-ft. level is 50 ft. above the floor of the level and is producing 3½ ft. of milling ore.

Tonopah Extension—In a raise from the 400-ft. level for the purpose of connecting with the Tonopah Mining Company's workings, 5 ft. of milling ore was opened up. In the raise 100 ft. west ore also shows and the two will be connected at a height of 70 ft. above the level.

West End—Development is being carried on the 200- and 400-ft. levels. The face of the west drift from the south crosscut on the 400-ft. level shows quartz carrying bunches of good ore.

NYE COUNTY—BULLFROG

Logland Lease—This lease on the Bullfrog National Bank estate made a 40-ton shipment to the smelter at Needles last week. Returns have not been received as yet, but mine assays give nearly \$100 per ton.

Oklahoma

Petroleum output for the month of January is reported at 3,630,030 bbl. Deliveries were 3,142,851 bbl., and 487,179 bbl. were added to stock. Total stocks were estimated at 53,392,143 bbl. at the close of the month.

Pennsylvania

BITUMINOUS COAL

Pennwood Coal Company—This company owns 1275 acres of coal land at Rockwood, in Somerset county, on which it has one mine in operation. It has made arrangements to buy two adjoining properties, 3900 acres in all. For this purpose, and to open additional mines, the company has decided to increase its stock from \$150,000 to \$1,000,000, and to authorize an additional issue of \$850,000 in 5 per cent. bonds, making a total of \$1,000,000 bonds outstanding.

South Dakota

LAWRENCE COUNTY

Elliptic—The diamond drill is now down 1200 ft., the deepest drill hole in the

Hills. The search for the quartzite has so far proved vain, but the drill is in a good porphyry.

Lucky Strike—Superintendent Allen has returned from Minneapolis, where he conferred with the large stockholders and was authorized to recommence work this spring on a larger scale. Development will be pushed and the mill will be operated all summer.

Rainbow—New officers were chosen as follows: President, E. P. Peterson; vice-president, E. M. Dale; secretary and treasurer, Clara D. Coe. The ground in the Maitland district is to be sold.

Portland & Clinton—Over 50 tons per day are shipped regularly, part to the mill at Terry and the higher grade to the Denver smelter. Machinery is being installed.

Cristoforo Colombo—This is a new company just organized by Italians to operate ground in the Two Bit district. The officers are: President, Victor Vigna; vice-president, A. R. Rizzuta; secretary, Martin Marchiano, and treasurer, Bart Trucano. Operations are to be started at once.

PENNINGTON COUNTY

Dakota Calumet—Work has been resumed under Superintendent Overpeck, at Sheridan, and the shaft will be sunk deeper through the copper formation. The smelter is also soon to be blown in.

Burlington—Superintendent Taylor will resume operations at Redfern soon, when the shaft will be continued from 180-ft. depth to 250, where drifting will start. A 2½-ft. vertical ledge carrying good ore, has been followed down the shaft.

Forest City—Reorganization of the old Clara Belle company has been completed by the Cleveland interests and a settlement reached with Frank Hebert, former owner. Work at Oreville will be commenced within a few weeks.

North Star—Frank Coughron is running 20 tons per day through the small Chilean mill on the ground near Rochford. He is planning to sink the shaft deeper.

Texas

Petroleum output in the Coastal district in January was 57,935 bbl. There were 34 new wells completed, of which 19 were oil producers, one a gas producer and 14 were dry holes.

Utah

BEAVER COUNTY

Honoring Extension—The first shipment from this mine shows 25 per cent. lead, 185 oz. silver and 600. gold. This ore was taken from the 800-ft. level. The orebody has been explored for 80 feet, and as yet no walls have been found.

The Milford-Utah—Development work will be resumed shortly at this property, which is a low-grade copper prospect.

Red Warrior—This property is shipping ore at regular intervals from its orebody on the 200-ft. level. The shaft is being deepened and other development work is carried on.

King David—This property now has its complete plant in operation, and will proceed to prospect the most promising portion of its claims. The company expects to catch the continuation of the orebody on the 400-ft. level of the Horn Silver mine.

Cactus—Since introducing the caving system a great economy has been effected. The orebody has been developed as far down as the 900-ft. level. Between 800 and 900 tons of 2-per cent. ore are passing through the mill daily, giving an output of 75 to 100 tons of concentrates.

Indian Chief—A tunnel has been run to cut the main fissure on this property, which lies north of the Indian Queen group.

SALT LAKE COUNTY

Utah-Philadelphia—The upper tunnel has cut 2 ft. of good lead-silver ore, carrying also copper and gold. The lower tunnel will soon cut the ledge at a depth of 150 ft. below the outcrop. The property is in Little Cotton Wood cañon.

UTAH COUNTY

Whirlwind—The narrow iron streak recently found in this property has widened into a 3-ft. vein of carbonates, high in silver and lead.

JUAB COUNTY

Iron Hat—An option has been taken on practically all the outstanding stock of this company at 10c. per share. The property is in the southeastern part of the Tintic district, and has a strong surface showing.

Black Jack—The east drift on the 1,400-ft. level has cut quartz and some ore. The property is now shipping iron ore to the Tintic smelter. The main shaft has a depth of 1,400 feet.

Wisconsin

ZINC-LEAD DISTRICT

Benton—At the Corr, two shafts are being sunk to open up the zinc ground at the south end of the property. At the Etna the new superintendent is reopening the mine, and has already secured a big showing in lead. The Dall has declared a 5 per cent. monthly dividend, and the Franklin one of 2 per cent. The fee of the old Sally Waters has been sold to the New Jersey Zinc Company.

Cuba City—Milwaukee men have bought the Grizzly Six and the Raisbeck.

The mines will be consolidated and reopened.

Hazel Green—The large shaft at the Cleveland is down 50 ft. Work has been stopped to wait the arrival of a larger pump. The power plant at the Murphy is being put in order, to furnish power to an adjoining mine. The Scabble Creek mine is shut down while a pair of 16-in. Cornish pumps is put in, to replace the old 10-in. pumps. The Vinegar Hill lost its pump house by fire, and the mine is full of water. New pumps have been ordered.

Platteville—The Enterprise has been unwatered and is making a good showing in the lower ground. The owners of the Hodge have been thrown into bankruptcy on application of the creditors.

Canada

BRITISH COLUMBIA

R. L. Broadbent, of the department of mines of Canada, recently left Ottawa for British Columbia, where he will make a selection of mineral specimens from those collected by local boards of trades and others, so as to insure having at the Alaska-Yukon-Pacific Exposition a collection representative of the mineral resources of British Columbia. Hon. Wm. Templeman, minister of mines, before leaving Victoria on his return to Ottawa after his recent re-election, visited Seattle, Wash., and there conferred with the Canadian exhibition commissioner, William Hutchison, relative to British Columbia's position in connection with the general Canadian exhibit.

BRITISH COLUMBIA—EAST KOOTENAY

Aurora—Two new strikes of ore are reported from the Aurora mine, situated across Moyie lake from the well known St. Eugene. In the breast of the main tunnel, at about 450 ft. from its portal, 18 in. of ore has been encountered, and No. 1 raise from this tunnel has run into 3 ft. of ore.

BRITISH COLUMBIA—SIMILKAMEEN

Camp Hedley—The season is opening favorably, with arrangements already made or being made for development work on several properties, beside the Nickel Plate mine which the Yale Mining Company has been operating here for five years, producing during that period about \$2,000,000 worth of gold from ore milled at the Daly Reduction Company's 30-stamp mill at Hedley. At the Golden Zone, where a small stamp mill was put in last year, work is in progress. The further development of the Kingston and Pollock groups, together with work on the Sacramento, Florence, and Apex properties, among others, makes the outlook for the year encouraging. In addition, material is being received at Keremcos for tracklaying on the Victoria, Vancouver &

Eastern Railway, a Great Northern subsidiary road, the grade for which is practically finished to Hedley and is being made thence to Princeton, at which place lignite coal is being mined.

BRITISH COLUMBIA—SLOCAN

Whitewater Camp—On the Whitewater Deep property, a recently incorporated company known as the Deep Mine. Ltd., managed by J. L. Retallack, of Kaslo, is driving a 1500-ft. tunnel at the level of the Kaslo & Slocan railway, a depth on the incline of about 2000 ft. below the apex of the vein, and 600 ft. lower than the old workings.

ONTARIO—COBALT DISTRICT

Ore Shipments—Shipments of ore from Cobalt for the week ending Feb. 20 were as follows: Buffalo, 44,730 lb.; Crown Reserve, 103,500; City of Cobalt, 60,000; Kern Lake, 60,130; La Rose, 258,730; Nipissing, 256,481; Right of Way, 182,589; Temiskaming, 60,000; Temiskaming & Hudson Bay, 60,000; total, 1,086,250 pounds.

Badger—The new plant, including a 12-drill compressor and two 100-h.p. boilers, is in operation, in charge of A. A. Smith. The main shaft is down 223 ft. on a vein varying from 2 to 24 in. in width, and carrying high-grade ore.

Chambers-Ferland—The shaft on the vein crossing from the O'Brien to the La Rose is down 140 ft., at which point the ore assays 4037 oz. silver to the ton. A cross-cut is being run from the 85-ft. level across that portion of the property where two rich veins were discovered last fall.

Columbus—Operations at this mine have been interfered with by a heavy flow of water. When cross-cutting at the 250-ft. level water was struck, which flowed in such volume that the men had some difficulty in escaping. Four pumps are now at work.

Gifford Extension—The main shaft is down 86 ft., and 300 ft. of drifting and crosscutting have been done at the 80-ft. level. A promising cobalt-calcite vein was encountered in crosscutting. Diamond drilling will test at depth a vein traced 50 ft. on the surface near the Progress location.

Silver Leaf—A good find was made in the drift at the 100-ft. level, the vein being 3 in. thick and the wall rock also rich in silver.

Trethewey—A new vein has been discovered on the north end of the property. It occurs on the 150-ft. level in a drift from the workings, continued from the Temiskaming & Hudson Bay property, and is about 4 in. in width.

ONTARIO—GOWGANDA

Bartlett—A contract has been closed for the immediate delivery of a plant compris-

ing two 80-h.p. boilers, an air-compressor and 10 drills.

ONTARIO—LEK LAKE DISTRICT

Gagin-Hamilton—The shaft is down 25 ft. on a calcite vein 14 in. wide carrying native silver. Camp buildings to accommodate 40 men have been erected and a compressor plant has been ordered. There are 13 well-defined veins on the property.

Mother Lode—Two good strikes were recently made at this mine, one of them disclosing a vein of high-grade ore about 12 in. wide.

ONTARIO—SAULTE STE MARIE

Lake Superior Corporation—Manager Franz states that the company will immediately commence extensive additions to the open-hearth furnaces of the steel plant. It is reported that the company will also erect new blast furnaces and a structural steel plant.

ONTARIO—SOUTH LORAIN

International Portland Cement Company—The annual meeting was held at Ottawa, Ont., Feb. 16. J. S. Irvin, managing director, stated that winter shipments for December and January showed an increase of 10,944 bbl. over the corresponding months last year. Orders for 150,000 bbl. in excess of the capacity of the plant were received during the year. The financial statement for the year ending Nov. 30, 1908, showed net profits of \$217,227. Two 5-per cent. dividends had been paid and \$68,227 carried forward to credit of profit and cost account.

Tallen Claim—An option on this property has been taken by Henry S. Hill, representing L. O. Demison, P. G. Lapey and H. C. Deuel, of Buffalo, who will develop the mine. A shaft is down 50 ft. on a calcite vein, and about 2000 ft. of trenching has been done disclosing about a dozen other veins.

NOVA SCOTIA

Nova Scotia Steel and Coal Company—At a meeting of the directors in Montreal a statement of the year's business for 1908 was presented. The total steel shipments amounted to 44,421 tons, as compared with 50,053 tons for 1907. The quantity of coal produced was the largest in any year of the company's history, being 718,654 tons. The profits were \$734,701, as compared with \$444,790 in 1907. The expenditure on capital account during the year was \$321,735.

Mexico

CHIHUAHUA

Rio Plata—The production in January not including that derived from tailings amounted to 60,100 oz. silver. Smelter returns for the month, 60 days after shipment, were \$27,569.

San Timoteo—T. A. Ripperdan, general manager, is making regular shipments of 500-peso copper-gold-silver ore from the mine in the Uruachic section to the southwest of Chihuahua. Several thousand tons of 50-pesos ore is also accumulated on the dump which is to be reduced to a high-grade matte in a 25-ton smeltery now in progress of installation.

Parral Mill—The milling plant of the Parral Mining Company in the Parral camp has been purchased by the American Zinc Extraction Company, owning and operating the Tajo mine in the same district. The work of remodeling the plant into a concentrating mill of initial capacity of 100 tons is now under way.

Colorados—High-grade gold-silver ore is reported uncovered at a depth of 275 ft. at this property in the Allende district. Robert Wilson is in charge.

Sta. Eulalia Exploration Company—This company has resumed production, sending its ore to the Chihuahua plant of the American Smelting and Refining Company. The managing director is Dr. H. Nelson Jackson, and the superintendent, J. H. Gilmore.

Cerro Colorado—Considerable activity is reported in this section lying to the east of Villa Ahumada on the Mexican Central. Two lead-silver properties, the Mexicana and the Mosqueteros, are under development by Geo. B. Jacobs and associates of Chihuahua and good orebodies are said to be exposed.

Los Lamentos—Regular shipments of zinc ores are in progress from the Squire-Peterson properties in this section to the east of Villa Ahumada. The operators recently closed a contract for the early delivery of 5000 tons of zinc carbonates.

Cerro del Fierro—The opening up of considerable bodies of high-grade lead-silver ore in the Alpha mine of this section is announced. The property is that of Jose de Riego and the district lies to the east of Moctezuma.

Batopilas—Recent ore discoveries have resulted in greatly increasing the output during the past few months. The December production was 201,000 pesos and the January 216,000 pesos. It is also given out that experiments with a view to the early installation of a cyanide plant are being carried out. The present mode of treatment is lixivitation, with or without previous roasting.

Parral Output—The production of the Parral district for the first 14 days of February amounted to, approximately, 16,000 tons. The output for the month of January was nearly 44,000 tons, of which 30,000 tons were milled locally. With the advent of several new shippers in the Santa Barbara section an increased production will probably be recorded for February.

Hinds Consolidated—Ross B. Matkins has resigned the management of the affairs of this Santa Barbara company and is succeeded by the former superintendent, J. J. Hallister. A regular production is being made from the Reforma and Clarines mines.

El Rayo—The January production is given as \$37,000. The new regrinding machinery should be in readiness now and the mill product thereby increased considerably. The upraise connections between the Pettit tunnel and Adela workings are about completed and this will increase the mine product. New ore discoveries are also reported on the lower workings of the Descubridora.

El Volcan—This company, organized and financed by Parral parties with Charles Gerhardt as president, is encouragingly developing properties in the San Juan de Minas district.

SONORA—NACOZARI

Production—Ore shipments for January over the Nacozari railroad were: Moctezuma Copper Company, 11,290 tons; Churunibabi, 408; El Tigre, 238; Esperanza, 10 $\frac{1}{4}$; El Temblor, 4; Fortuna, 98; Bella Union, 254; San Pedro, 81; Mina Alta, 41 tons; and silver sulphides from the Lampazos properties of Sr. Lopez of an estimated value of \$10,000. The total estimated valuation was: Copper, \$1,238,500; gold, \$63,000; silver, \$127,000; total, \$1,438,500.

El Aguaje—A Mexican company has been formed by the promoters of this mine, the stock of which will be taken by an American corporation.

Cañillo—The Silver Seal Mining Company is shipping ore from the mine to the Douglas smelter. F. O. Colson is superintendent, address Nacozari, Sonora.

Copper Plate—N. S. Finch has returned from Los Angeles, and will proceed at once on the development of this group of properties, east of Pilares.

La Caridad—The Minaret Mining Company is installing a diamond drill to develop this mine, east of Nacozari.

Monte Cristo—This property has been taken by the new holders, and will be equipped with a steam plant, which is now on the road from Nacozari. C. H. Jones is manager, address Moctezuma, Sonora.

Pura Plata—Geo. F. Woodward is shipping high-grade silver ore from this property, formerly worked by *antiguos*. It is being opened up by shafts and tunnels below the old workings.

Transvaal Mining Company—The company has resumed operations on its Transvaal and Ultima Chanza properties with 50 men and expects to increase its force. H. C. Beauchamp is manager and Tom L. Davenport, superintendent, address, Campas

QUOTATIONS FROM IMPORTANT CENTERS

Coal Trade Review

New York, March 3.—The coal trade in the West shows very little change in conditions. Some closing of contracts for steam coal is reported in the western distributing centers, but the general statement is that consumers are not eager to make contracts believing that their chances will be better on an open market. Moreover, a good many consumers are still uncertain about their requirements. The weather in the West has moderated generally and domestic coal is dull.

The coke market in Pennsylvania shows some signs of overproduction, and prices for short deliveries have been lower. Quite a number of plants in the Connells-ville district have been closing down temporarily. Shipments, however, show a considerable improvement over last year.

The Seaboard bituminous trade continues quiet and without special incident. Very few mines supplying that trade are able to run on full time, or with a full force.

In the anthracite trade the discussion of a probable strike is still the chief topic. No official statement has been made of the intentions of the anthracite companies, but it is pretty well understood that they will reject all the demands of the miners. A suspension at least, if not a strike, appears to be certain at the end of the present month. How long it will last is, of course, entirely a matter of conjecture. There is every probability, however, of a long discussion.

COAL TRAFFIC NOTES

Tonnage originating on Pennsylvania railroad lines east of Pittsburgh and Erie, year to Feb. 20, short tons:

	1908.	1909.	Changes.
Anthracite.....	742,547	691,112	D. 51,435
Bituminous.....	4,561,516	4,854,380	I. 292,864
Coke.....	1,015,669	1,405,271	I. 389,602
Total.....	6,319,732	6,960,763	I. 641,031

Total increase this year to date is 9.8 per cent.

Bituminous coal and coke shipments, Pennsylvania and West Virginia, year ended Dec. 31, short tons:

	Coal.	Coke.	Total.
Balt. & Ohio.....	24,499,973	3,115,903	25,615,876
Buff. Roch. & Pitts.	5,516,221	336,488	5,852,709
Buff. & Susquehanna	1,194,816	212,934	1,407,750
Penn. Busk. N. Y. C.	6,991,122	71,706	7,062,828
Pitts. & L. Erie.....	8,129,629	3,656,395	11,786,024
Norfolk & Western	11,207,943	1,953,869	13,161,812
Total.....	55,598,704	8,747,295	64,345,999
Total, 1907.....	66,723,041	13,686,663	80,409,704

The total decrease in 1908 was 16,123.-

705 tons, or 20.1 per cent. In addition to the above the Baltimore & Ohio carried 1,020,274 tons anthracite in 1907, and 866,344 in 1908; decrease, 213,930 tons.

Coal tonnage of railroads in Ohio Coal Traffic Association, year ended Dec. 31, short tons:

	1907.	1908.	Changes.
Hocking Valley.....	4,093,672	3,304,002	D. 789,670
Toledo & Ohio Cent.	1,790,640	1,383,763	D. 406,876
Baltimore & Ohio.....	2,312,838	1,440,363	D. 872,475
Wheeling & L. Erie.....	3,473,378	2,721,723	D. 751,655
Cleveland, Lorain & Wb.	3,004,162	2,417,814	D. 586,348
Zanesville & Western	1,575,129	1,289,133	D. 285,994
Toledo Div., Pen. Co.	2,342,883	1,570,416	D. 772,467
L. Erie, Alliance & Wb.	1,244,319	1,102,055	D. 142,264
Marietta, Col. & Clev.	40,091	56,166	I. 16,075
Total.....	19,877,121	15,485,437	D. 4,391,684

The total decrease in 1908 was 22.1 per cent.

Coal receipts at St. Louis for the full year were 8,145,308 short tons in 1907, and 6,890,286 in 1908; decrease, 1,255,022 tons.

Coal shipments by water from Seattle and Tacoma, Wash., were 700,628 tons in 1907, and 471,451 in 1908; decrease, 229,177 tons. These shipments are mainly to California and Alaska ports.

Coastwise shipments of coal from leading Atlantic ports for the year ended Dec. 31 were as follows, in long tons:

	Anthracite.	Bitum.	Total.	Perc't.
New York.....	15,069,981	10,247,014	25,316,995	62.5
Philadelphia	2,164,747	4,675,767	6,840,514	16.8
Baltimore.....	251,739	3,704,851	3,956,590	9.8
Newport News.....	2,742,294	2,742,294	5,484,588	13.8
Norfolk.....	1,651,093	1,651,093	3,302,186	8.1
Total.....	17,486,467	23,021,019	40,507,486	100.0
Total, 1907, 19,491,494	24,584,619	44,066,113	63,650,612	

Total decrease in 1908 was 3,508,627 tons, or 8 per cent. The decrease in anthracite was 1,945,027, and in bituminous, 1,563,600 tons.

Sales of bunker coal to steamships in coastwise and foreign trade, year ended Dec. 31, at all United States ports:

	1907.	1908.	Changes.
Atlantic.....	7,114,224	7,005,623	D. 108,601
Gulf.....	684,659	616,676	D. 67,983
Pacific.....	936,291	583,326	D. 352,966
Great Lakes.....	2,664,471	2,325,979	D. 338,492
Total.....	11,299,645	10,531,603	D. 768,042

Of the bunker coal reported in 1908 vessels in Coastwise trade took 4,734,036 tons; in foreign trade, 5,797,767 tons. The large decrease at Pacific ports is mainly due to the increased use of oil as fuel on steamers.

New York

ANTHRACITE

March 3.—The market continued in about the same condition as last week. Business in prepared sizes is quiet and there is still some coal being stored. The demand for steam sizes keeps up to the

usual level and supplies are not overabundant. Probably there will be no surplus as long as the mines continue to run on short time.

Prices are unchanged. The list prices for prepared sizes are \$4.75 for broken, and \$5 for egg, stove and chestnut. Small steam sizes are: Pea, \$3.25@3.50; buckwheat No. 1, \$2.35@2.50; buckwheat No. 2 or rice, \$1.60@2; barley, \$1.35@1.50; all f.o.b. New York harbor points.

BITUMINOUS

The principal occupation of the market seems to be the discussion of season contracts. Not many have been closed, as buyers are not disposed to offer more than current prices, and producers are reluctant to accept these.

Current business is moderate. The far East has not begun to take any coal yet, but the Sound is doing a little better, though quantities are not very large. New York harbor is very quiet, the disposition being to wait and watch for chances to pick up coal at a bargain. Shipments, however, are pretty well gaged to the demand. Prices f.o.b. New York harbor points continue about the same at \$2.40@2.50 for good grades of steam coal, with lower grades at \$2.20@2.30 per ton.

All-rail trade is fair—that is, it is better than Seaboard. Car supply is abundant and transportation good, cars coming through on schedule time or a little better.

The Coastwise market is dull and vessels are still looking for charters. There is no change in freight rates, those quoted for large vessels from Philadelphia being: Boston, Salem and Portland, 75c; Lynn and Bath, 85c; Portsmouth, 80c; Newburyport, 95c; Providence, New Bedford and the Sound, 65@70c per ton.

Birmingham

March 1.—The coal demand in Alabama is not extensive, and it does not take a large number of mines to produce enough to go around. The production in this State is at a low ebb, and there is no telling when improvement will set in. The coal operators are hopeful, though they have nothing to base their hope on.

The coke production is again at a low mark. There is small demand for the product.

Chicago

March 2.—Conditions in the coal market continue fairly favorable to the wholesaler. Shipments have been in general

kept down, and the demand has not fallen off notably, despite somewhat milder weather. Steam coals are increasing in demand; this fact offsets the slackening in the domestic trade which comes with each mild-weather spell. The situation as regards smokeless is still one of too large supply for the maintenance of circular prices. Anthracite is hard to dispose of, and there is much independent coal in the market at cut prices, though dealers do not look for large sales at any prices through this month.

Illinois and Indiana coals bring \$1.80@2.40 for lump, \$1.60@1.75 for run-of-mine, and \$1.30@1.60 for slack. The fine-coal sales are increasing with the expansion of steam needs; lump is falling off correspondingly. Domestic needs are expected now to become light in city and country trade for Western bituminous generally.

Of coals from east of Indiana, Hocking continues in good condition with little or no cutting of the \$3.15 circular price, and with a fair demand. Smokeless brings \$3.15@3.45 for lump and \$2.75@3.15 for run-of-mine. Pocahontas and New River, with lower-grade smokeless, 10@20c. less. Youghiogheny is quiet and steady at \$3.15 for 34-in. gas; Pittsburgh No. 8 is plentiful and not very active at \$2.65@2.75 per ton.

Cleveland

March 2—The domestic coal market is less active, as milder weather has set in. Country dealers, however, are still taking a fair quantity of coal.

Steam coal is improving a little in demand, especially for slack, which is not in as free supply as run-of-mine. The market is looking rather better on this side.

Indianapolis

The Indiana Legislature made considerable progress during the past week. Among the bills relating to mines and miners that were advanced are the following: The Foos House bill, providing for weekly payments of wages in coal mines; the Bassett House bill, requiring lavatories or washrooms to be maintained at coal mines where 10 or more men are employed; the Kayser bill, to establish boards of examiners for coal miners to issue certificates upon examination, and providing that no miner shall be employed in any mine in the State unless he hold such certificate, except he be an apprentice; and a bill for reciprocal regulation of demurrage charges on loaded railroad cars. It is thought all of these bills will be enacted into law during the present week.

Pittsburg

March 2—The coal business has not improved since the prices in iron and steel products were cut and an open market

declared, but the large producers have not made any change in prices. The regular price for coal for prompt delivery, however, has been a concession as the contract price is charged, small independents selling at a trifle less. The contract price remains on the basis of \$1.15 a ton for mine-run coal at mine, and slack continues around 70c. Several fairly good contracts for coal have been placed with large interests by steel companies and more are expected as soon as conditions brighten up and confidence is restored for the future. The Monongahela River Consolidated Coal and Coke Company, the Jutte interests and other large river shippers have been doing a good business since the rivers became navigable several weeks ago. The last shipment of coal went out on Sunday night, and while there is a good, navigable stage, no coal is being sent out for the reason that all has been shipped and there is not sufficient coal in the harbor to make up one good tow. There are plenty of empty coal boats and barges in the pools and harbor and the river mines are running practically full. The railroad mines, however, are not being operated to more than one-third of capacity.

Connellsville Coke—New business likely to follow the open-market conditions in the iron and steel trade has not yet brought out the trade expected so far, and coke prices remain about the same. The asking prices for furnace coke for spot delivery up to July 1 are \$1.75, and for foundry \$2@2.25. It is reported that some furnace coke for spot shipment has been sold as low as \$1.60, but foundry has not fallen below \$2. The *Courier* gives the production in the two Connellsville field at 265,619 tons. The shipments aggregated 9366 cars as follows: To Pittsburgh district, 3316; to points west of Connellsville, 3312; points west of Connellsville, 738 cars.

Foreign Coal Trade

United States Coal Exports—The coal furnished for the use of steamships in foreign trade at United ports for the year ended Dec. 31 is given below; to which are added the exports, previously reported:

	1907.	1908.	Changes.
Exports.....	13,152,749	11,853,177	D. 1,299,572
Bunker coal.....	5,754,176	5,797,467	I. 43,291
Total.....	18,906,925	17,650,644	D. 1,256,281

This shows a decrease of 6.6 per cent. in the total coal sold for consumption beyond the limits of the United States.

Welsh Coal Prices—Messrs. Hull, Blyth & Co., London and Cardiff, report current prices of coal as follows, on Feb. 20: Best Welsh steam, \$3.36; seconds, \$3.24; thirds, \$3.12; dry coals, \$3.48; best Monmouthshire, \$3.06; seconds, \$2.94; best small steam, \$2.10; seconds, \$1.80. All per long ton, f.o.b. shipping port.

Iron Trade Review

New York, March 3—The iron and steel markets have not yet fairly adjusted themselves to their new bearings. There is some uncertainty existing, but an increase begins to be apparent in the volume of business, and in all probability another week or 10 days will see the trade established on a fairly stable basis.

No settlement has been reached about the rail question, and there is no change in prices so far. The Cambria Steel Company, at Johnstown, Penn., has begun work on a small order of 2500 tons of open-hearth rails for the Norfolk & Western railroad. These are the first open-hearth rails from this plant.

In pig iron the market is uncertain. Shading of prices on Northern iron is pretty generally reported, but it is difficult to ascertain its amount. Southern iron has settled down to a basis of \$12.50 for No. 2 foundry, Birmingham, and some orders are reported taken at 25 and even 50c. less. The merchant furnaces, both North and South, are apparently in a state of uncertainty.

Structural material, after some fluctuation, has apparently settled down to a basis of 1.20@1.25c., at which price a number of contracts have been placed.

It is announced today that the New York Central has placed orders for 101,000 tons of steel rails, as follows: Lackawanna Steel Company, 51,000; Steel Corporation, 42,600; Algoma Steel, 5400 for use in Canada; Bethlehem Steel Company, 2000 tons open-hearth. The price is not made public, but is reported to be under \$38 on the revised specifications.

It is announced today that the Lackawanna Steel Company has ordered a general reduction of 10 per cent. in wages. This action was not unexpected at this plant, and Buffalo dispatches say that it will be generally accepted by the employees—possibly under protest, but with no talk of a strike. The reduction is general in all branches of the works. The question raised by this action is to what extent it will be followed by other companies.

The Senate committee, which has been considering the merger of the Tennessee Coal, Iron and Railroad Company with the United States Steel Corporation, has decided to make no formal report at this session. The committee was nearly evenly divided in opinion.

Open-hearth Steel—The production of open-hearth steel in the United States in 1908 was 7,780,872 long tons; a decrease of 3,768,864 tons, or 32.6 per cent. from 1907. The decrease was much less than that in bessemer, and the open-hearth exceeded the bessemer production by 1,664,117 tons—the first time such an excess has been shown. Of the metal made in 1908 acid steel was 606,304, and basic 7,084,568 tons.

Baltimore

March 2—Exports for the week included 50 steel ore cars and 1,769,651 lb. structural steel to Nipe Bay, Cuba; 580,091 lb. tin scrap to Rotterdam. Imports included 38 tons spiegeleisen and 953 tons ferromanganese from Liverpool; 6300 tons manganese ore from Vizigapatam, India; 5800 tons iron ore from Cuba.

Birmingham

March 1—Very little change is to be reported in the pig-iron market in the Southern territory. The market is dull; there are very few orders being received and what are coming in are in small lots. The quotations in this territory are weak. No. 2 foundry is quoted at \$12.50 per ton. There is still a good quantity of iron being shipped out on old orders, but it will not be long before these orders will be at an end.

The cast-iron pipe concerns in Southern territory are the only successful people. There is no cessation of operations at the pipe works, and the product is being shipped out as rapidly as it is manufactured, with good prices.

The conditions at the steel plants are not as prosperous as they might be, though all the rails produced are shipped out promptly.

Chicago

March 2—The pig-iron market continues quiet, with a feeling of uncertainty apparent among melters as to the effect of lowered steel prices. Probably nine out of ten melters are looking for a drop in pig iron; with such a feeling they continue to buy small quantities of iron and for delivery soon. The total volume of sales is doubtless increasing, even on these small lots, testifying to greater current needs and to the betterment of business. On such sales \$12.50@13 Birmingham (\$16.85@17.35 Chicago), and \$16.50@17 are the prices for No. 2 iron; a large quantity of either Northern or Southern doubtless could be had at lower prices.

In the market for iron and steel products there is still much hesitancy and doubt on the part of buyers as to the effect of the Steel Corporation's new prices and consequently reluctance to buy heavily. There is also a tendency to look forward to tariff changes as a further cause of unsettled conditions and a disposition to hold off until those changes become known. It is largely, therefore, a waiting market.

Philadelphia

March 3—The only marked change this week over last is a cut in some standard

grades which have been held up, regardless of all competition and all reason. Even the shadings offered have not up to present hour resulted in the placing of large orders. Some Southern makers have been making new efforts to unload pig iron in this territory, which they will probably do. The producing interests are anxious to reduce their accumulation but will have to wait a while longer.

Bars—Store people report this week a still further improvement in retail selling of merchant iron, particularly refined.

Sheets—Sheets of all kinds under the further reductions have begun to move more freely.

Pipes and Tubes—A further marking down has not developed much business, but large buyers are disposed to close soon at the reductions.

Merchant Steel—A fine amount of business has been done this week in the way of supplying stores throughout this territory.

Plates—Small orders for plates are more numerous. The plate mills are temporarily well fixed.

Structural Material—Construction requirements of a local nature are about ready for consideration and a number of fair orders will go to the mills, probably next week.

Scrap—The entire scrap market is in a chaotic condition over the general lowering of prices for finished material, and comparatively little is selling. A few dealers are caught with scrap that they cannot sell at present asking prices.

Pittsburg

March 2—The declaration of an open market in iron and steel products, with the exception of steel rails and tinplate, has not brought out any new business of any consequence. Consumers were not prepared for the move and had been looking for a straight cut in some of the commodities. They are now waiting to inform themselves of the real prices at which finished material can be obtained. The matter will be readjusted within the next week, or two weeks at the farthest, and producers are preparing for an active buying movement. It is possible that the tariff revision may cause a delay in buying, but there are hopes that when the special session of Congress is held the importance of prompt action will be realized and the new bill will be disposed of in short order. This, undoubtedly, will restore confidence to a certain extent and new spring orders will be forthcoming. The difficulty in obtaining new prices on finished material can be readily seen when the general sales manager of one of the largest interests said today: "If you want 10,000 tons and the order is a bona fide one I will give you a rate." It is

generally understood that all prices are cut from \$4 to \$7 per ton, with the exception of merchant-steel pipe, which will run fully \$10 per ton. There is no cut in prices of tinplate at present, as both the American Sheet and Tin Plate Company and the independent concerns are well filled with orders for the spring trade at the old rates. Business has been unusually good since the opening of the year and a number of large orders are in sight and will be closed as soon as it is known that tinplate is not included in the general slashing of prices. New prices in sheets being named by the American company are known. They are based on \$6 per ton off on Nos. 29 and 30 gages of black sheets, \$5 on No. 28 and \$4 on No. 27 and heavier. On galvanized sheets the cut is \$3 on Nos. 29 and 30, \$5 on No. 28 and \$4 on No. 27 and heavier.

One of the important finished lines where no reduction has been announced is wire and wire products. The old prices apparently prevail, but it is believed that if the jobbers can be induced to come into the market for their usual spring requirements and fill up their warehouses they will be benefited by some fairly good concessions. Active buying by jobbers is certain to come shortly, as the spring demand will be good despite the unfavorable conditions that have prevailed for over a year. No new price in steel billets is being given and the old rate of \$25, Pittsburg, is still supposed to be the market on both bessemer and open-hearth billets, and \$27.50 on sheet-bars. This is due to the fact that most of the billets and sheet-bars sold have been on sliding contracts. All the steel men here seem to take a cheerful view of the future, but in the absence of new business have nothing to give out but brighter prospects. The American Bridge Company has not taken on any new orders since the cut in structural shapes of \$6 to \$7 per ton, although there are known to be some large contracts for new buildings pending. The only cause assigned is that people are waiting for actual base prices.

Pig Iron—The market has not improved and dull conditions likely will continue until the steel situation clears. The bessemer average for February was \$15.87½, Valley furnaces, or \$16.77½, Pittsburg. The price named for spot shipment today is \$15.50, Valley furnace, a cut of over 25c. per ton. Basic is lower and \$15 can be shaded. Malleable bessemer and No. 2 foundry are quoted at \$15 and gray forge at \$14. These are practically cost prices and it is not likely that the market can go any lower.

Sheets—Black sheets are quoted at 2.20c. and galvanized at 2.30c. for No. 28 gage.

Ferro-Manganese—There has been a drop in prices, and 80 per cent. is now quoted at \$44.50@45, Pittsburg.

Metal Market

New York, March 3—A greater activity is reported in the metal markets generally, and considerable sales of copper have been made. There has, however, been no material advance in prices.

Gold, Silver and Platinum

UNITED STATES GOLD AND SILVER MOVEMENT

Metal.	Exports.	Imports.	Excess.
Gold:			
Jan., 1909....	\$ 7,865,196	\$ 3,412,583	Exp. \$4,452,613

Year 1909....	4,542,254	3,660,052	Exp. 882,202
" 1908.....	4,148,144	3,621,874	Imp. 526,270

Exports from the port of New York, week ended Feb. 27: Gold, \$1,069,220, chiefly to Argentina; silver, \$934,661, to London and Paris. Imports: Gold, \$351,053, from South and Central America; silver, \$48,627, chiefly from Mexico.

Gold—The price of gold in the open market in London has been steady at 77s. 9d. per ounce for bars, and 76s. 4d. per ounce for American eagles. In New York shipments of gold to Argentina on London account amounted to \$2,650,000 for the week.

Platinum—Business is not active, although sales are improving a little. Dealers quote \$23.50@24.50 per oz. for refined platinum, \$26 for hard metal and \$19@21 for scrap.

SILVER AND STERLING EXCHANGE

Feb.-Mar.	25	26	27	1	2	3
New York....	50½	50½	50½	50½	50½	50½
London.....	23½	23½	23½	23½	23½	23½
Sterling Ex. .	4.8735	4.8760	4.8750	4.8750	4.8760	4.8765

New York quotations, cents per ounce troy, fine silver; London, pence per ounce sterling silver, 0.925 fine.

Silver—Owing to frequent China sales, the market has scarcely been steady. The inquiries have been more than satisfied and silver has shown a slightly declining tendency, with inquiries at the close of business today at 23¼d. in London.

Copper, Tin, Lead and Zinc

Feb.-Mar.	Copper.		Tin.	Lead.		Zinc.

"	12¼	12¼	"	3.92½	3.77½	4.57½
2	12¼	12¼	57½	3.92½	3.77½	4.57½
"	12¼	12¼	"	3.92½	3.77½	4.57½
3	12¼	12¼	56½	3.92½	3.77½	4.57½

London quotations are per long ton (2240 lb.) standard copper. The New York quotations for electrolytic copper are for cakes, ingots and wirebars, and represent the bulk of the transactions made with consumers, basis, New York, cash. The price of cathodes is usually 0.125c. below that of electrolytic. The quotations for lead represent wholesale transactions in the open market. The quotations on spelter are for ordinary Western brands; special brands command a premium.

Copper—Beginning on Feb. 24, some large sales of electrolytic copper were made to Europe, and these continued to March 2, the aggregate of the sales being probably upward of 50,000,000 lb. The demand developed at first from foreign speculators at the lowest prices, which were established during the last three days of February. Subsequently manufacturers followed suit, buying large amounts of copper than for three months previous. On March 1 sellers raised their prices, evidently thinking that news of the previous sales would stimulate purchases by the manufacturers in this country who are known to be low in their supplies. There did, indeed, result a more active inquiry, and some sales of moderate amounts were made to them, but so far the volume has been disappointing. However, there are bids in the market for domestic consumption at somewhat below the current quotations, which have not met with much encouragement, owing to the ready market in Europe. Some sales of Lake copper have been effected and certain large interests are now asking 13¼c. for this grade, at which price a few small sales of fancy brands have been made. The close is firm at 12¾@13¼c. for Lake copper and 12½@12¾c. for electrolytic copper, in ingots, cakes and wirebars. The average of the week for casting copper has been 12¼@12½ cents.

Copper sheets, cold-rolled, are quoted 17.3c. per lb., large lots; and hot-rolled, 16.5c. Copper wire, 1¼c. base, carload lots at mill. Wire has been reduced 0.75c. this week.

The London Standard market had a rapid rise which culminated on March 2, when the quotation reached £58 2s. 6d. for spot, £58 17s. 6d. for three months. Due to a weaker tendency, frightened holders endeavored to realize the following day, and when this was noticed by the alert bear element, it took the market away from the sellers and established at the close quotations at £56 15s. for spot, £57 10s. for three months.

Statistics for the second half of February show an increase in the visible supplies of 100 tons.

Refined and manufactured sorts we quote: English tough, £61; best selected, £60@61; strong sheets, £72@74.

Throughout February the copper market was dull and saggy. Sales were unusually small, manufacturers having well provided for their requirements by purchases in previous months, while the knowledge of the large stock of metal

accumulated in the hands of American refiners caused both speculators and European buyers to hold aloof with the expectation that prices would go lower, which was indeed realized. The United Metals Selling Company, which at the beginning of the month was holding for 14½c. delivered, 30 days, later on reduced its price to 13½c., same terms, but the market being already a trifle below that figure, no good purpose was served by the nominal reduction on the part of the leading interest. The small business that was offered was eagerly competed for by various agencies, wherefore the price declined still further. During the last week of February a basis of 12¾c. was reached, which at last interested European buyers, and in the last four days of the month some fairly large sales for export were consummated.

Tin—The statistics for the end of February, which disclosed a decrease in the visible supplies of 1300 tons, were a favorable influence in the market in London. While bare of the usual spectacular movements, prices held firm and the close is cabled at £130 for spot, £131 10s. for three months.

In the domestic market an almost entire absence of demand on the part of consumers is again noticeable, but prices remain stationary at about 28.75 cents.

Lead—Business in this metal continues rather slow and the few orders which come into the market are eagerly competed for. The close is barely steady at 3.77½@3.80c. St. Louis, 3.92½@3.95c. New York.

The London market has been somewhat weaker, and the close is cabled at £13 7s. 6d. for Spanish lead, £13 10s. for English lead.

Spelter—There has been a much better inquiry throughout the week. It would appear that the distress lots which have had so depressing an influence on the market during the last few weeks have been eliminated. Smelters are reluctant to sell large quantities since they cannot make a new dollar for an old one, and all these causes combined have contributed to bring about a slow advance. Another factor in the situation has been the strong tendency of the London market, which has brought the quotation up to the export point. The close is firmer at 4.57½@4.62½c. St. Louis, 4.72½@4.77½c. New York.

The price of spelter at New York, Feb. 25-27, was 4.67½@4.72½c.; March 1 it was 4.70@4.75c., and March 2-3, it was 4.72½@4.77½ cents.

The London market is again higher, the close today being cabled at £21 17s. 6d. for good ordinaries, £22 2s. 6d. for specials.

Base price of sheet zinc has been reduced 0.25c. to 63½c. per lb. f.o.b. La Salle-Peru, Ill., less 8 per cent. discount.

Other Metals

Antimony—The market is still quiet, but a little more business has been done. Quotations are 8@8½c. per lb. for Cookson's; 7¾@7½c. for U. S., and 7½c. for ordinary brands.

Aluminum—Business is steady, with no change. The Aluminum Company of America quotes 24c. base for No. 1 ingots; 33@34c. base for sheets. Foreign metal is quoted at 22c. for ingots, but no business is reported.

Quicksilver—Business is rather better, and sales are increasing. The New York price is unchanged at \$45@46 per flask of 75 lb. San Francisco quotations are nominal at \$45@46 for domestic orders, and \$43@44 for export. London price is £8 7s. 6d. per flask, with £8 5s. named by jobbers.

Nickel—Large lots, contract business, 40@45c. per lb. Retail, from 50c. for 2000-lb. lots up to 55c. for 500-lb. lots. These quotations are for spot nickel. The price for electrolytic is 5c. higher.

The Monel Metal Company has been incorporated with a capital stock of \$1,000,000. It is a subsidiary of the International Nickel Company, and will, it is understood, handle the Monel metal made by the Orford Copper Company. This metal is an alloy of 70 per cent. nickel and 30 per cent. copper made directly from Canadian matte, and is being brought into extensive use.

Cadmium—Current quotation 75c. per lb., in 100-lb. lots, at Cleveland, Ohio.

Magnesium—Quotations for this metal are \$1.25 per lb., New York, in 100-lb. lots; for 5-lb. lots, \$1.40 per pound.

Zinc and Lead Ore Markets

Platteville, Wis., Feb. 27—The base price for 60 per cent. zinc ore this week was \$38. No premiums were paid. Lead ore, 81 per cent., sold at \$46 per ton.

SHIPMENTS, WEEK ENDED FEB. 27

Camps.	Zinc ore, lb.	Lead ore, lb.	Sulphur ore, lb.
Platteville	396,340	100,000	
Cuba City	302,340	68,440

Year to Feb. 27	17,917,586	656,180	1,490,200

In addition there was shipped to the Joplin Separator Works, at Galena, 206,800 lb.; to the American Zinc Ore Separating Company, 65,900 lb. zinc ore.

Joplin, Mo., Feb. 27—The highest price paid for zinc sulphide was \$40 on a base of \$38 per ton of 60 per cent. zinc, the base ranging down to \$35 for slimes. The bulk of the ore sold on \$37@37.50 base. Zinc silicate sold as high as \$25 per ton, the base ranging from \$19 to \$21. Aver-

age all grades zinc, \$34.66. Lead sold on \$48 to \$49.50 base, all grades averaging \$48.80 per ton.

The shipment and output were large, the shipment being in excess approximately 200 tons, reducing the bin stock to about 6600 tons. The weather is as near perfect for mining operations as could be ordered, and a number of new mills are to be commissioned soon.

NOTE—Under zinc ore the first two columns give base prices for 60 per cent. zinc ore; the second two the average for all ores sold. Lead ore prices are the average for all ores sold.

Chemicals

New York, March 3—While a little more business is being done the general market is still far from active. Consumers seem to be in considerable doubt about filling their requirements for any distance ahead.

Copper Sulphate—The market is unchanged, with business on a moderate basis. Prices are unchanged at \$4.60 per 100 lb. for carload lots and \$4.85@4.95 per 100 lb. for smaller parcels.

Arsenic—Business is on a moderate scale, and prices unchanged at 3@3½c. per lb. for white arsenic.

Nitrate of Soda—A little more business has been done and indications are for

some improvement. Prices remain at 2.15c. for spot and 2.12½c. for futures.

Messrs. Mortimer & Wisner, New York, report the position of nitrate in the United States on March 1 as follows, in long tons:

	1908.	1909.	Changes.
Stocks, Jan. 1	5,900	9,140	1. 3,240
Imports 2 months	32,900	47,100	1. 14,200
Total Supplies	38,800	56,240	1. 17,440
Deliveries 2 months	35,800	50,310	1. 15,510
Stocks, Mar. 1	2,000	5,900	1. 3,900
Afloat for U. S.	65,000	82,500	1. 17,500

Quantities afloat include all cargoes due to arrive at United States ports before June 15 next.

Mining Stocks

New York, March 3—The general stock exchange has shown a good degree of recovery from the low point of last week, although the advance has been spotty and irregular. Stocks, however, are selling on a higher level as a rule. The recovery seems to be due to several causes, among which may be named the covering of shorts; the fact that last week's recession went rather too far; some confidence in a future rise, and perhaps the determination to work up a bull market after the inauguration. As usual, the causes of the change are composite and it is difficult to give any one the preference. The liquidation, though short, was fairly sharp and there was a general dropping out of weak holders which leaves a rather stronger undertone.

Two sales of Homestake of South Dakota were recorded, 100 shares changing hands at \$92.75 per share and 200 shares at \$92.50.

On the Curb the copper shares, which displayed considerable weakness at first, rallied on reports of better sales and prices of metal. A considerable business was done in these shares on advances over last week's quotations. Miami and Cumberland-Ely were the leaders in the movement. Business in the Cobalt stocks was rather large, but prices were unsteady and several declines were evident. The Nevada gold stocks were rather dull, business being only moderate, but prices remained generally on about the same level.

Boston, March 2—It has been a week of violent fluctuations in mining shares, although in a majority of cases recoveries have been quite as rapid as the earlier declines. The much heralded deal between the Calumet & Hecla and A. S. Bigelow, which was made late last month, did not have the salutary effect on the market that many had looked for. As a matter of fact it proved a decided depressing factor, but on second sober thought sentiment completely changed. Previous to this announcement Osceola

sold up \$5 to \$133, but broke to \$122 with subsequent recovery to \$131. Calumet & Hecla broke \$40 to \$685 per share, but has managed to recover all but \$5 of the decline. The fact that Calumet, in its settlement, saw fit to issue \$5,000,000 of notes, running three, five and ten years, was the unsettling factor. However, the general demoralization of the copper market contributed to this result. There was a ready market for the notes.

By the sale, the Bigelow interests dispose of their entire interest in the Lake Superior mining region, including Osceola, Tamarack, Ahmeek, Seneca, Isle Royale and Laurium properties. The number of shares involved is about 125,000, Calumet paying partly in cash and partly in the notes. Tamarack shot up \$10 to \$90, went back to \$82 and recovered to \$80.50 again. Isle Royale rose \$3 to \$31.50, but closed tonight at \$30.25. Amalgamated fell \$5.50 to \$65, which is its lowest for a long period; subsequently it rallied to \$71.37½. Copper Range broke \$3 to \$68.50, but is up to \$76.50 tonight, and North Butte broke from \$69.50 to \$67.25, touching \$71.25 today. East Butte has behaved admirably and is up \$3 to \$15.75.

The Victoria contest resulted in two new directors from the opposition. Ahmeek held around \$150 on the Curb. Private sales of Oneco are reported at \$2, \$3 and \$4 per share, against a nominal value of 50c. to \$1 for some years. This is due to developments on the Edwards tract, which it adjoins.

THE MINING INDEX

The editors of this paper read all the important publications of the world that relate to mining and the treatment of minerals. This index is published as a reference for all interested and to make it impossible for readers of the **ENGINEERING AND MINING JOURNAL** to miss any important article published anywhere.

We will undertake to furnish a copy of any article (if in print) in the original language, for the price quoted. Where no price is quoted the cost is unknown. These papers are not kept in stock, but must be ordered from the publisher; hence there will be some delay for foreign papers.

No accounts can be opened for these small amounts, but remittance must be sent with order. For the convenience of those making small but frequent remittances, coupons are furnished at the following prices: 20 cents each, six for \$1.00, thirty-three for \$5.00 and one hundred for \$15.00. This arrangement will be especially appreciated by foreign readers and men in distant mining camps. Where remittances are made in even dollars we will return the excess over an order in coupons upon request.

ASPHALTUM.

8639—USE of Asphaltum. H. Larkin. (Journ. Assn. of Eng. & Arch., Dec., 1908; 10 pp.) This paper relates to the various uses of asphaltum; gives a brief history of the industry. 40c.

CEMENT.

8640—ACTION OF FROST on Cement and Cement Mortar, together with other Experiments on These Materials. E. R. Matthews and J. Watson. (Proc. A. S. C. E., Jan., 1909; 14 pp.) This paper describes in detail a series of experiments extending over two years, made in order to ascertain the effects of frost and alternate frost and thaw on the tensile strength of cement when mixed with fresh water, also when mixed with sea water.

8641—SILICA IN PORTLAND CEMENT—The Determination of Silica in Portland Cement. W. P. Gano. (Chem. Eng., Jan., 1909; 12 pp.) A series of experiments upon the determination of silica in Portland cement to show the errors that are to be met with in the usual methods used in its determination. 40c.

CLAYS.

8641a—CANADA—Our Visible Supply of Brick. M. B. Baker. (Can. Min. Journ., Feb. 15, 1909; 2½ pp.) Describes the chief types of brick clay in Eastern Canada with especial reference to economic value of each. Gives chemical analyses. 20c.

8642—MISSISSIPPI—Clays of Mississippi. Part II. W. N. Logan. (Bull. No. 4, Miss. State Geol. Surv., 1908; 72 pp.) A description of the brick clays and the clay industry of Southern Mississippi. Illustrated. 20c.

COAL AND COKE.

8643—ACCIDENTS—Economy as Related to Mine Accidents. H. E. Coll. (Eng. and Min. Journ., Feb. 13, 1909; 2 2/3 pp.) Fearless discussion of the lax conditions that exist, showing that the coal operator eventually pays a heavy price for the present neglect. 20c.

8644—ANALYSIS of Coal and the Determination of the Caloric Value Therefrom. A. Caddick. (Pract. Eng., Jan. 15, 1909; 1½ pp.) Gives methods for determining moisture, volatile hydrocarbons, sulphur and fixed carbon. 20c.

8645—CANADA—C. P. R. Collieries in the West. L. Stockett. (Can. Min. Journ., Jan. 1, 1909; 1½ pp.) A review of the operations of the Hosmer Mines, Ltd., and the Bankhead Mine, Ltd. 20c.

8646—CHARCOAL—Wood Charcoal and the Chemistry of Carbonization. Z. P. Yuon. (Chem. Tr. Journ., Jan. 23, 1909; 2 pp.) This article is based on an exhaustive series of experiments in wood distillation extending over a number of years. Illustrated. 40c.

8647—CHINA—The Coal Mining Industry in China in 1908. N. F. Drake. (Min. Wld., Jan. 30, 1909; 2 pp.) Considerable advancement in coal mining has been made during the year, and the author describes the development of a number of the principal fields. 20c.

8648—COAL DUST PROBLEM—The Present Position of the Coal Dust Prob-

lem. James and John Ashworth. (Can. Min. Inst., Jan. 1909; 8 pp.) The authors submit the opinion that coal dust is the most dangerous factor in all collieries, particularly where fire damp is produced.

8649—COKE OVEN GAS PLANT—A Modern Coke Oven Gas Plant. (Elec. Rev., Jan. 22, 1909; 2 pp.) A description of the Barwood Colliery installation of the Powell Duffryn Steam Coal Company. Illustrated. 40c.

8650—COLLIERY EQUIPMENT—Surface Plant at Crigglestone Colliery, near Wakefield. (Coll. Guard., Jan. 15, 1909; 1 p.) A description of the Lührig washers and the installation of Otto-Hilgenstock coke ovens. Illustrated. 40c.

8651—CONVEYING—Swinging Chutes for Coal Mines. Lestelle and Hyve. (Eng. and Min. Journ., Feb. 13, 1909; 1½ pp.) An illustrated description of the construction and the comparative costs of operating various chutes. Abstract from Bull. de la Soc. de l'Industrie Minière, Mar. 1908. 20c.

8652—ELECTRIC SHOT FIRING in Coal Mines. D. Harrington. (Eng. and Min. Journ., Jan. 30, 1909; 4 pp.) A discussion of a system installed in Utah where all shots are fired from the surface and the works are clear of men. Illustrated. 20c.

8653—EXPLOSION of Fire Damp at White Haven Colliery. R. A. S. Redmayne. (Min. Engineering, Feb., 1909; 5½ pp.) A description of the mine, its equipment, and the conditions of the mine after the explosion. Illustrated. 20c.

8654—EXPLOSIONS—Coal Mine Explosions in the United States in 1908. (Min. Wld., Jan. 30, 1909; 3 pp.) An enumeration of the principal explosions during the year. Some remarks on their causes. The discussion of a test requirement for explosives used in coal mining. 20c.

8655—MINING METHOD—Working The Seams in Los Proximité. V. F. White. (Min. Engineering, Feb., 1909; 1 p.) Description of a method employed in working two seams of coal which have but three feet of strata between them. Illustrated. 20c.

8656a—FORMATION OF COAL—Pressure in the Formation and Alteration of Coal. D. B. Dowling. (Can. Min. Journ., Feb. 15, 1909; 1½ pp.) Describes the theoretical relation between pressure and the amount of gas in coal. 20c.

8656b—MINING METHODS for Maximum Recovery of Coal. H. V. Hesse. (Eng. and Min. Journ., Feb. 6, 1909; 6 pp.) A discussion of early systems of mining the George's Creek coal which only recovered about 50 per cent. of the seam. A description of the mining operations in this article insure a recovery of 95 per cent. Illustrated. 20c.

8657—NEW SOUTH WALES—The New Castle Colliery, New South Wales. J. Reed. (N. Z. Mines Rec., Nov. 16, 1908; 2 pp.) A description of the mining operations on the bord-and-pillar system, according to the most modern practice employed by the Hebburn colliery and the South Biddulph colliery. 40c.

8658—NEW ZEALAND—Coal Mining Methods in New Zealand. F. Reed. (N. Z. Mines Rec., Dec. 16, 1908; 2 pp.) A description of mining methods, haulage

and ventilation. The use of electricity in collieries. 40c.

8659—PEAT—Commercial Aspects of Gasifying Peat. R. Schorr. (Journ. Am. Peat Soc., Jan., 1909; 13 pp.) A discussion of the peat problem in general and the manufacture of peat coke, peat generator gas and by-products. 80c.

8660—PHILIPPINE COALFIELDS. J. B. Dilworth. (Trans. A. I. M. E., Jan., 1909; 12 pp.) The author deals with the markets, labor and mining costs, together with the geology of these coalfields. He also gives some chemical analyses. 40c.

8661—SCOTLAND—The Marine Beds near the Base of the Upper Carboniferous Red Barren Measures of Scotland. J. Smith and C. T. Clough. (Coll. Guard., Jan. 23, 1909; 1½ pp.) An account of the discovery of marine beds at Palaeocraig, together with the collection of marine fossils which may be of service in correlating the strata in the coal measures proper. Illustrated. 40c.

8662—STORAGE—Ferroc-Concrete Coal Storage Plant. (Coll. Guard., Jan. 22, 1909; 1½ pp.) A description of the Hennebique ferroc-concrete system of coal bins and their mechanical equipments as used at Clayton West and Skelmanthorpe Collieries. Illustrated. 40c.

8663—WASHERY—The Cardiff Coal Washery. (Coll. Guard., Jan. 22, 1909; 5 pp.) A description of the washery of the Cardiff Washed Coal Company, Ltd., which has a capacity of 4000 tons daily. Illustrated by photographs and detailed plans. 40c.

8664—WEST VIRGINIA—Department of Mines Bulletin. J. W. Paul. (Dept. of Mines, W. Va., Oct., 1908; 32 pp.) A compilation of the inspectors' reports from the various districts, together with a chapter on accidents. 20c.

COPPER

8665—BRONZES—Composition of the Modern Bronzes. C. Vickers. (Foundry, Feb., 1909; 2 pp.) A discussion of the deoxidizing elements used in copper alloys for increasing their tensile strength and ductility. 20c.

8666—CANADA—The Importance of Low-Grade Boundary Ores in the Copper Production of Canada. A. B. W. Hodges. (Quart. Bull. Can. Min. Inst., Sept., 1908; 12 pp.) The author gives a brief review of the work that has been done in the district and emphasizes the possibilities for future developments. 20c.

8667—SINTERING at Cerro de Pasco. (Min. and Sci. Press, Jan. 30, 1909; 1 p.) A description of a sintering furnace recently installed by the Cerro de Pasco Mining Company. Illustrated. 20c.

8668—SMELTER—The Pink Smelter at the Boston Consolidated. C. W. Higgins. (Salt Lake Min. Rev., Jan. 30, 1909; 4 pp.) A description of the furnace, its operation and a comparison in costs with other smelting methods. Illustrated. 20c.

8669—SMELTER—The Steptoe Valley Smelting Plant, McGill, Nevada. L. Humphreys. (Min. Wld., Feb. 6, 1909; 4 pp.) A description of the smelter, roasters, concentrators, power department, general buildings, water facilities, the mines and the transportation of the ore. Illustrated. 20c.

8670—SOUTH AFRICA—Messina Copper. (South African Min. Journ., Dec. 2, 1908; 1½ pp.) Report by Mr. Calderwood, consulting engineer of the company, on the progress of development, and the valuable ore reserves. He also gives some statistics on capital expenditure and ore production in this district. 40c.

8671—TENNESSEE COPPER COMPANY in 1908. B. B. Gottsberger. (Eng. and Min. Journ., Feb. 6, 1909; ½ p.) Brief notes on developments in mining and smelting during 1908. 20c.

GOLD AND SILVER.

8672—ALLUVIAL MINING—Deep Lead Alluvial Mining in Victoria. F. Reed. (N. Z. Mines Rec., Dec. 16, 1908; 3 pp.) A description of the mining methods, hoisting, haulage and the electrically driven Cornish pumps. Illustrated. 40c.

8673—AUSTRALIA—The Bendigo Goldfield. Victoria. F. Reed. (N. Z. Mines Rec., Dec. 16, 1908; 2 pp.) Notes on deep mining in Bendigo; the equipment for hoisting and treatment of the ore. 40c.

8674—AUSTRALIA—The New Loch Pine Gold Mine. Matlock, Victoria. J. Trevor. (Aust. Min. Stand., Dec. 2, 1908; 2 pp.) Some notes on the geology of the district. A description of the mine plants, the crushing plant and the treatment of the ore. Illustrated. 40c.

8674a—CALIFORNIA—Mining at Grass Valley and Nevada City. G. E. Wolcott. (Eng. and Min. Journ., Feb. 20, 1909; 2½ pp.) Describes mines and methods of camp, including lowering by "go-devil" in the North Star slopes. Illustrated. 20c.

8675—COLOMBIA—Gold Mining in Colombia. F. L. Garrison. (Min. and Sci. Press, Feb. 6, 1909; 6 pp.) A description of the country, its geography, geology and placer gold deposits. Also notes statistics on the amount of gold and silver produced since the 16th century. Illustrated. 20c.

8676—CYANIDATION—B. and M. Circulating Tank. F. C. Brown. (Aust. Min. Stand., Dec. 9, 1908; 2 pp.) A description of the tank for the agitation and circulation of large charges of concentrates, sand, pulp or slimes with cyanide or other solutions. Illustrated. 40c.

8677—CYANIDATION—Continuous Cyanide Treatment. J. L. Mennell. (Mex. Min. Journ., Feb. 1909; 2½ pp.) An outline of a system of continuous cyanide treatment in which the well-known Pachuca tanks are connected and operated in series, the first receiving the pulp from the mill and the last discharging same continuously by gravity to the filter plant. Illustrated. 20c.

8678—CYANIDATION—Filtering Gold Slime. E. Jensen. (Aust. Min. Stand., Dec. 9, 1908; 2 pp.) A description of a simple and effective contrivance which is a good substitute for a filter press. The whole operation of washing and filtering can be done in the acid tub. The principle involves vacuum filtration. Illustrated. 40c.

8679—CYANIDE PRACTICE—The Electrochemistry of the Solution of Gold in Potassium Cyanide. J. B. Ekeley and A. L. Tatum. (West. Chem. and Met., Jan. 1909; 1 p.) The record of a series of experiments with varying strengths of cyanide solution, to determine whether the gold requires oxygen for its solution in potassium cyanide. 50c.

8680—CYANIDING OPERATIONS in Mexico During 1908. M. E. Lamb. (Min. Wld., Feb. 6, 1909; 4½ pp.) A review of the progress made during the year, together with notes on a number of the principal cyanide plants in Mexico. Illustrated. 20c.

8681—IDAHO—The Congr. d'Alene Mining District, Idaho.—VII. J. P. Fowler. (Min. Wld., Feb. 13, 1909; 2 1/3 pp.) This article gives a description of the Bunker Hill and Sullivan mine and mill, together with some notes on the Last Chance, Sierra Nevada and the Stewart mines. Illustrated. 20c.

8682—LOW-GRADE ORE TREATMENT—Treating Low-Grade Ore at the Comstock Lode. A. H. Martin. (Min. Sci., Jan. 21, 1909; 2 pp.) A description of the plant of the Butters' Company, and the methods employed in the eco-

nomical treatment of these ores. Illustrated. 20c.

8683—MILL-TEST for Gold vs. the Assay. H. E. Haultain. (Can. Min. Journ., Jan. 1, 1909; 2 pp.) A comparison of the two methods in which the author shows that the assay is far more reliable than the mill test. 20c.

8684—MINING METHODS—Methods of Mining the Granby Orebodies. C. M. Campbell. (Eng. and Min. Journ., Jan. 30, 1909; 4½ pp.) Advance sheets from Journ. Can. Min. Inst., Vol. X.) A description of a method used in large underground deposits requiring little timbering. Electric power is used for haulage and operating air compressors and pumps. Illustrated. 20c.

8685—NEVADA—Mining and Milling at Rawhide, Nevada. G. E. Wolcott. (Eng. and Min. Journ., Feb. 13, 1909; 3 2/3 pp.) A description of the geology, ore bearing areas, orebodies, the mines and milling operations as conducted in this district. Illustrated. 20c.

8686—NEVADA—Ore Formation in the Wonder District, Nevada. E. A. Ritter. (Eng. and Min. Journ., Feb. 6, 1909; 1 p.) A discussion of the rocks and minerals, also of the vein structure as occurring in this district. Illustrated. 20c.

8687—NORTH CAROLINA—Progress of Gold Mining in North Carolina. E. W. Lyon. (Eng. and Min. Journ., Feb. 6, 1909; 4½ pp.) A description of mines which were large producers prior to the Civil War. These mines are again attracting attention, and many have been re-opened in a small way. The author also gives some notes on the geology of the ore deposits in North Carolina. Illustrated. 20c.

8688—NOVA SCOTIA—Leipsic Gold Mining District, Nova Scotia. P. H. Mooney. (Min. Wld., Feb. 13, 1909; 3 pp.) A description of the district, its geology, character of ore, principal mines, production and development. Illustrated. 20c.

8689—ONTARIO—Cobalt in 1908. A. Gray. (Min. Journ., Jan. 16, 1909; 1½ pp.) This article takes up the Cobalt district as a whole, analyzes the output and gives tables of statistics from 1904 to date. 40c.

8690—PLACER MINING—Successful River-bed Prospecting by Compressed Air. W. D. Egilbert. (Min. Sci., Feb. 4, 1909; 1½ pp.) The description of a novel method of prospecting placer beds by blowing water and air by means of caissons. Illustrated. 20c.

8691—RHODESIA in 1908. W. F. Wilkinson. (Eng. and Min. Journ., Jan. 30, 1909; 1 p.) A few notes on the working costs in Rhodesia, together with a statement of the gold production for the year 1908. 20c.

8692—SAMPLING—The Goldfield Consolidated Sampling Mill. A. Churculary. (Eng. and Min. Journ., Feb. 6, 1909; 1½ pp.) A description with detailed drawings of the sampling mill for an ore supply of 600 tons in eight hours. 20c.

8693—SAMPLING AND VALUATION—Development—Sampling and Ore Valuation of Gold Mines. C. B. Harwood and M. Park. (Trans. A. I. M. E., Jan. 1909; 10 pp.) This paper is intended to call attention to some essential features of good practice in sampling and valuation. The author divides mine sampling into two classes: First, development-sampling and computation of ore reserves, and second, stope sampling, and estimation of stope values. Illustrated. 20c.

8694—TUBE MILLING PRACTICE: Position Today. (So. African Min. Journ., Jan. 2, 1909; 1½ pp.) This article gives some notes on the use of tube mills in South Africa. Also the names of the companies using them. 40c.

8695—YUKON LUTCH. The. T. A. Rickard. (Min. and Sci. Press, Jan. 23, 1909; 4 pp.) Continuation of article previously indexed. This instalment takes up the Ballarat division, and gives a description of both flume and pipe construction. Illustrated. 20c.

8696—YUKON GOLD COMPANY—Operations of the Yukon Gold Company. (Eng. and Min. Journ., Feb. 6, 1909; 1½ pp.) Reprint of a letter to the stockholders of the Yukon Gold Company which was issued by the President, S. R. Guggenheim, January 30, 1909. 20c.

IRON AND STEEL.

8697—ALLOY STEEL—The Nature and Treatment of Alloy Steel. J. A. Matthews. (Iron Age, Jan. 7, 1909; 2 pp.) A discussion of nickel, chrome-nickel and chrome-vanadium steels; the need of apparatus for testing and the noteworthy result of heat treatment. 20c.

8698—BLAST FURNACE PLANTS—Some American Blast Furnace Plants—II. (Engineer, Jan. 15, 1909; 1½ pp.) The second of a series of articles on this subject in which is given a description of the Swedenland furnaces in Pennsylvania; also the Vauxhall furnaces of the Birmingham Coal & Iron Company. Illustrated. 40c.

8699—CHINA—Steel Making in China. T. D. Morgan. (Iron Age, Feb. 4, 1909; 2 pp.) A description of the works at Hankow, their labor conditions and iron ore and fuel supplies. Also some notes on the Chinese market and the United States. 20c.

8700—CUPOLA PRACTICE—A Suggested Change in Cupola Practice. R. Mendenhall. (Am. Foundrymen's Assn., 1908; 8 pp.) It is the purpose of this paper to give the probable cause of spongy spots and pin holes in castings, and suggest a remedy for their prevention.

8701—ELECTRIC FURNACE—New Resistance and Induction Furnace. Alfred Gradenwitz. (Eng. and Min. Journ., Feb. 13, 1909; 1½ pp.) A description of the Röchling-Rodenhauser electric furnace recently installed in some of the German iron works which is a combination of the resistance and induction furnaces. Illustrated. 20c.

8702—ELECTRIC FURNACES—The Gröndal-Kjeller Electric Furnace. Rodenhauser Electric Steel Furnaces. (Engineering, Jan. 22, 1909; 2 pp.) A description of experimental work done by an induction furnace of the Gröndal-Kjeller type together with short description and illustrations of its construction. Briefly mentions the Röchling-Rodenhauser furnace. 40c.

8703—ELECTROMETALLURGY—The Progress of the Electrometallurgy of Iron and Steel. A. Stansfeld. (Can. Min. Journ., Feb. 1, 1909; 1 p.) The application of electrically-generated heat to the production of iron and steel is one of the most recent and is becoming one of the most important branches of electrometallurgy. The author gives some notes on the improvement in design and increase in the size of furnaces. 20c.

8704—FOUNDRIES IN ALABAMA. W. B. Phillips. (Mfrs. Rec., Jan. 1909; 2 pp.) In this article an effort has been made to give a list of the principal foundries in Alabama. There is no intention of including establishments that undertake ordinary repairs, but such only as are consumers of pig iron. 20c.

8705—FOUNDRY PRACTICE—Preliminary Report of Committee on Prevention of Accidents in Foundries. (Am. Foundrymen's Assn., Sept., 1908; 8 pp.) Gives some statistics on accidents occurring in foundries, due to various causes.

8706—HIGH-SPEED STEELS—The Nature and Character of the New Steels. O. M. Becker. (Eng. Mag., Feb., 1909; 15 pp.) The article here presented deals with the physical constitution of high-speed steels, and the phenomena of tempering. Illustrated. 40c.

8707—IRON ORE MINING in Great Britain. L. C. Ball. (Queensland Gov. Min. Journ., Feb. 13, 1909; 2½ pp.) A description of the mines and mining methods of the Eston and Montreal mines. Also statistics of their output. Illustrated. 60c.

8708—MALLEABLE CASTINGS—Production of Malleable Castings.—XI. R. Cholden. (Foundry, 1909; 6 pp.) A discussion of various methods of cleaning and inspection; the annealing department and methods of packing the castings and charging the furnaces. 20c.

8709—METALLOGRAPHY—Notes on Metallography. W. G. Haldane. (West. Chem. and Met., Jan., 1909; 6 pp.) In this paper the author deals briefly with the metallography of iron and steel. Illustrated. 80c.

8710—OHIO—Mahoning Valley as an Iron Center. J. F. Froggett. (Iron Tr. Rev., Jan. 21, 28 and Feb. 4, 1909; 12 pp.)

This article gives an historical review of this district, including a description of the rolling mill development from the earliest days, the first tin plate made in this country, use of natural gas in the large rolling mills, the organization of the Ohio Steel Co., etc. 60c.

8711—RUSSIAN IRON TRADE CONDITIONS. (Iron Age, Jan. 21, 1909; 2 pp.) A discussion of the proposed pool of the South Russian Iron Works. Also some notes on the future of the Ural district. 20c.

8712—SAMPLING IRON ORES.—Methods of Sampling Iron Ore, J. M. Camp. (Iron Tr. Rev., Jan. 20, 1909; 2 1/2 pp.) A description of the systems of commercial sampling as adopted by the United States Steel Corporation, and described in a booklet issued by that company. Illustrated. 20c.

8713—SOUTHERN IRON ORE.—A Great Southern Iron Ore Reserve. W. B. Phillips. (Mines Rec., Feb. 4, 1909; 1 1/2 pp.) This article briefly describes a number of the ore deposits in the valley of the Tennessee river. 20c.

8714—STEEL PLANT.—The Works of Indiana Steel Company—II. (Iron Tr. Rev., Feb. 4, 1909; 12 pp.) Second article of series describing the blowing engine and power plants of the works at Gary, Ind. Also the utilization of the furnace gases. Illustrated. 20c.

8715—SWANZY IRON ORE DISTRICT. (Iron Tr. Rev., Jan. 7, 1909; 2 1/2 pp.) A review of the operations of the Cleveland Cliffs Iron Company together with an outline of plans for the future. Illustrated. 20c.

8716—TURBINE INSTALLATION.—A Notable Low Pressure Turbine Installation. (Iron Age, Jan. 7, 1909; 5 pp.) A description of a Rateau regenerator and a 600-Kw. turbo-generator set at Vandergrift, Penn., supplying direct current at 250 volts. Illustrated. 20c.

8717—VANADIUM. Compared with Other Steel Alloys. G. Auchy and J. K. Smith. (Iron Age, Jan. 21, 1909; 2 pp.) A discussion of the value of vanadium, with tables of statistics in which it is compared with chromium, tungsten and nickel. 20c.

8718—VANADIUM.—The Use of Vanadium in Cast Iron. J. K. Smith. (Foundry, Feb. 1909; 2 1/2 pp.) A discussion of the action of this metal on gray iron for casting purposes and the methods of application in the ladle and air furnaces. 20c.

NICKEL.

8720—CANADA.—The Nickel Trust. A. Gray. (Min. Journ., Jan. 16, 1909; 2 pp.) The author gives a review of the nickel mining industry in Canada, together with tables showing the production of nickel and copper in the Sudbury district. Also some notes on the operations of the International Nickel Company. 40c.

8721—ONTARIO.—The Nickel-Copper Industries of Ontario in 1908. A. Gray. (Min. Wid., Jan. 30, 1909; 3 pp.) A review of this branch of the mining industry during the year, together with some notes on the output, dividends, etc., of a number of the larger companies. Also a table of the production of nickel and copper in the Sudbury district since 1886. 20c.

PETROLEUM.

8722—CALIFORNIA.—Coalinga Oil District, California. R. Anderson and R. Anderson. (Bull. 357, U. S. Geol. Surv., 1908; 142 pp.) A preliminary report on the geology and oil resources of the Coalinga district, Fresno and King counties, California. Illustrated. 40c.

8723—GALICIAN PETROLEUM INDUSTRY. (Petrol., 1908; 2 pp.) A review of the petroleum industry and statistics of the output of 1908. Illustrated. 40c.

8724—MEXICAN PETROLEUM. The Tuxpan Oil Well Fire. D. Floy. (Eng. News, Dec. 10, 1908; 1 1/2 pp.) A short review of the development of the petroleum industry in Mexico. A description of the Tuxpan oil well, the fire and the method employed in extinguishing it. 20c.

8725—PRODUCTION OF Petroleum In 1908. D. T. Day. (Min. Wid., Feb. 6, 1909; 2 1/3 pp.) A review of the indus-

try for the year with notes and statistics on the various fields in the United States. 20c.

PHOSPHATE ROCK.

8726—UNITED STATES.—The Present Phase of Phosphate Rock in the United States. J. Campbell. (Ann. Fertilizer, Jan. 19, 1909; 1 1/2 pp.) A short review of the phosphate industry in the United States. 20c.

PRECIOUS STONES.

8727—DIAMOND MINING INDUSTRY of South Africa. O. Letcher. (Min. Wid., Jan. 30, 1909; 1 p.) A review of the depression in the mining industry; the effect of recent discoveries; the operations restricted at Kimberley, and the policy of the Premier company. 40c.

8728—DIAMONDS.—Some Facts and Corrections Regarding the Diamond Region of Arkansas. J. C. Branner. (Eng. and Min. Journ., Feb. 13, 1909; 1 1/2 pp.) A discussion of the article on the Arkansas Diamond Field by John T. Fuller, which appeared in the Journal Jan. 16, 1909. 20c.

QUICKSILVER.

8719—PURIFICATION.—An Apparatus for the Purification of Mercury. L. J. Desha. Amer. Chem. Journ., Feb. 1909; 3 pp.) The description of an automatic apparatus which operates continuously for a given lot of mercury and requires absolutely no attention after once being started. Illustrated. 60c.

RARE METALS.

8729—URANIUM.—Rare Metals.—VIII. Chas. Baskerville. (Eng. and Min. Journ., Jan. 30, 1909; 1 1/3 pp.) This article gives a description of a number of uranium minerals together with localities in which they are found. Blowpipe reactions are also given. 20c.

8730—VANADIUM AND URANIUM.—Rare Metals. H. Fleck. (Quart. Colo. Sch. of Mines, Jan., 1909; 51 pp.) Results of an investigation of the vanadium deposits in the region of Placerville, San Miguel Co., Colo. The author gives some of the geologic conditions, describes a number of vanadium deposits and gives analyses of the ores. Contains also brief notes on the occurrence of uranium in Gilpin Co., Colo.

TIN.

8731—AUSTRALASIA.—The Occurrence of Stannite in Australasia. H. Conder. (Aust. Min. Stand., Nov. 18, 1908; 1 p.) A description of this mineral, its analyses and geological occurrence; also a description of the Onah mine. 40c.

8732—DETINNING INDUSTRY. The Electrochem. and Met. Ind., Feb. 1909; 3 pp.) A review of the detinning processes and a description of the Goldschmidt tin and chemical works in Essen. Illustrated. 40c.

8733—SOUTH AFRICA.—The Tin Deposits of the Cape Peninsula. (So. African Min. Rec., Dec. 1908; 2 pp.) Some notes on the various companies that have been formed for mining tin in this district. A short description of the placer tin deposits. 40c.

8734—TIN DRESSING.—Notes on Tin Dressing. C. Brackenbury. (Inst. of Min. and Met. Bull., No. 52, Jan. 14, 1909; 2 pp.) Contributed remarks in which the author gives a series of experiments showing a great variation between vaning assays and chemical assays of tin ore.

TUNGSTEN

8735—WOLFRAM ORES.—Occurrences and Uses. Chas. Bognereder. (Aust. Min. Stand., Dec. 9, 1908, and 23, 1908; 5 pp.) Continuation of a series of articles on the importance of these ores in Australia and to commerce in general. The author takes up the mineralogy, and mentions the locations in which the various minerals are found; contains also some notes on the metallurgy of tungsten. \$1.00.

ZINC

8736—ELECTROLYTIC RECOVERY OF ZINC. W. Stoeger. (Min. Journ., Jan. 30, 1909; 1/2 p.) A description of a process

in which the zinc blende is roasted and is then lixiviated with dilute sulphuric acid. The liquor is purified and the zinc is deposited by the electric current. 40c.

8737—SMELTING WORKS.—The Central Zinc Company's Works at Leadon Carew. (Engineering, Jan. 29, 1909; 2 1/2 pp.) A description of the plant and operations of the Central Zinc Company which was recently formed by the Sulphide Corporation and the Zinc Company of Broken Hill. The plant has a capacity of 35,000 tons of zinc blende per annum. Sulphuric acid is also manufactured as a by-product. Illustrated. 40c.

8737a—TENNESSEE.—The East Tennessee Zinc Mining District. S. H. Osgood. (Eng. and Min. Journ., Feb. 20, 1909; 3 1/2 pp.) Describes district, ore occurrences and mining and milling operations. Illustrated. 20c.

ECONOMIC GEOLOGY—GENERAL.

8738—IGNEOUS ROCKS.—Grain of Igneous Rocks—Practical Uses of Its Observation. A. Chance. (Min. Sci. Jan. 1909; 13 pp.) The author endeavors to show how, by the study of crystallization, many of the problems of mining may be simplified. 20c.

8739—IGNEOUS ROCKS.—The Study of Igneous Rocks. J. P. Idings. (Science, Feb. 5, 1909; 17 pp.) An address delivered by the author before the American Association for the Advancement of Science, Baltimore, 1908. A successful treatment of the subject of igneous rocks as they are treated by the author would place petrology on a more rational foundation. 20c.

8740—MONTANA.—Geology and Water Resources of the Great Falls Region, Montana. C. A. Fisher. (U. S. Geol. Surv., Water-Supply Paper 221, 1909; 89 pp.) A discussion of the geology, surface waters, underground waters, the chemical character of water, and the utilization of water for power and irrigation purposes. Illustrated. 20c.

8741—IRON DEPOSITS.—Theory of Volcanic Action and Ore Deposits, Their Nature and Cause. H. W. Hixon. (Inst. of Min. and Met. Bull., No. 52, Jan. 14, 1909; 12 pp.) The basis of the theory which is here set forth is that the earth was at one time an incandescent sun, in which condition its temperature was above the critical temperature of all the matter of which it was composed. Illustrated. 20c.

8742—ORE DEPOSITS.—The Genesis of Various Types of Ore Deposits. G. O. Marrs. (Min. Sci., Jan. 21, 1909; 2 1/2 pp.) A brief statement of some of the forms of ore occurrence with sketches illustrating the few simple rules given. 20c.

8743—ORE OCCURRENCE.—Why Are Mining Camps Centers of Mineralization? A. Lakes. (Min. Sci., Jan. 28 and Feb. 4, 1909; 4 pp.) The first and second of a series of articles in which the various forms of ore occurrence in different sections are compared and correlated. The author describes the ore deposits of the Boulder-Jimtown area, and of Clear Creek, Colorado. 40c.

8744—SECONDARY IMPOVERISHMENT.—An Instance of Secondary Impoverishment. H. H. Knox. (Inst. Min. and Met. Bull., No. 52, Jan. 14, 1909; 12 pp.) The author discusses the occurrences of unoxidized iron sulphides which have been leached of their copper contents as being of sufficient occurrence to merit their description. Illustrated. 20c.

8745—UTAH.—Some Salient Features of the Geology of Newhouse, Utah and Vicinity. J. Jensen and others. (Dept. of Geol., Univ. of Utah, June, 1908; 35 pp.) The authors discuss the general geology of the district, together with its topographical features. Special reference is also given to the economic geology, and a description of a copper mine is included. 40c.

8746—WYOMING.—Geology and Mineral Resources of the Laramie Basin, Wyoming. N. H. Darton and C. E. Sieben- tian. (Bull. 364; U. S. Geol. Surv., 1909, 81 pp.) A preliminary report on the geology, general mineral resources, and underground waters of the Laramie district. Illustrated. 40c.

MINING—GENERAL.

8747—ACCIDENTS.—Prevention of Accidents in Metal Mines. Claude T. Rice.

(Eng. and Min. Journ., Feb. 6, 1909; 5 pp.) A discussion of accidents due to over-winding; accidents in shafts; accidents with explosives and those due to poisonous acids at metal mines. Accidents due to carelessness are preventable and it should be the duty of the superintendent to see that the miners are not careless. Illustrated. 20c.

8748—BRITISH COLUMBIA—Mineral Production of British Columbia in 1908. (Eng. and Min. Journ., Jan. 30, 1909; 4 pp.) Statistics showing the output of gold, copper, silver, zinc, lead and iron. Also coal and coke. 20c.

8749—CALIFORNIA—Report of the Board of Trustees and State Mineralogist, L. E. Aubrey. (Cal. State Min. Bureau, Nov. 1, 1908; 27 pp.) A report on the Museum and the Hammond Library. The mineralogist's report covers the work that has been done during the year, and also gives a résumé of the condition of the mining industry.

8749a—CANADA—Recent Progress in the Mineral Industry in the Thunder Bay and Rainy River Districts. (Can. Min. Journ., Feb. 15, 1909; 2 pp.) Discusses the present state of these districts, and outlines the recent prospecting for iron, gold and silver. 20c.

8750—COMPUTING TONNAGE from Volume of Ore Removed. S. L. Lefevre and G. C. Stoltz. (Eng. and Min. Journ., Feb. 15, 1909; 2 pp.) A description of the method used for computing tonnage as employed by the Port Henry Iron Ore Company and Witherbee, Sherman & Company in the iron mines at Mineville, N. Y. Illustrated. 20c.

8751—DRILLING—Some Features of Diamond Core Drilling. III. C. J. McCord. (Min. Wld., Jan. 16, 1909; 2½ pp.) The author points out a number of instances in which the diamond drill has been known to deflect from the perpendicular, and suggests methods for detecting this deflection. Illustrated. 20c.

8752—ENGLAND—Cumberland Minerals. W. W. Barnes. (Chem. Tr. Journ., Jan. 23, 1909; ¼ pp.) A short review of the mining industry with special reference to arsenical pyrites, sulphides of antimony, barytes and fluor spar. 40c.

8752a—EXPLOSIONS—Mine Explosions as Related to Earthquakes. W. A. Spalding. (Eng. and Min. Journ., Feb. 20, 1909; 3 pp.) A discussion favoring the view that the danger from explosions in deep mines is augmented during periods of seismic unrest. 20c.

8753—FOREIGN COUNTRIES—Review of Mining in Foreign Countries. (Eng. and Min. Journ., Jan. 9, 1909; 14 pp.) A review of the present state of the mining industries of the Transvaal, Peru, Chile, Colombia, Mexico, Ontario, and Australia. Details of the gold production. 20c.

8754—GASES RESULTING FROM THE USE OF HIGH EXPLOSIVES. Wm. Culbertson. (Jour. of Chem. Med. and Soc. of South Africa, Nov. 1908; 7½ pp.) The author records a series of experiments which were conducted in drifts on developing work. A sample of the mine gas was generally before blasting at a certain point, and also immediately after blasting. He has tabulated his chemical analyses. 60c.

8755—GREAT BRITAIN—Twenty-five Years of Mining. E. Ashmead. (Min. Journ., Nov. 1908; 2 pp.) A retrospective review, 1880-1904, of mining companies registered in Great Britain, with notes and comments, and the names and capitals of the principal registrations. The present statement deals with companies operating in the United States and Canada. 40c.

8756—HAULAGE—Endless Rope Haulage. Geo. Farmer. (Sci. and Art of Min., Jan. 23, 1909; 2½ pp.) A mathematical calculation of endless rope haulage. 20c.

8757—IDAHO—Tenth Annual Report of the Mining Industry of Idaho for the Year 1908. Robert N. Bell. (Boise, Idaho, 1908; 23 pp.) The report of the Inspector of mines for the year 1908, giving a short review of the mining industry of the various counties of the State. Also a table giving the mineral output by counties.

8758—LABOR—Mexican Labor in the United States. Charles B. Bureau. (Bureau of Labor, No. 78, Sept. 1908; 9 pp.) A discussion of the Mexican laborer in the mining districts of the Southwest, covering the advantages and disadvantages of this class of labor and a com-

parison of efficiency with other nationalities.

8759—MANAGEMENT—Labor-Chart for the Management of Mining and Milling Operations. J. Macdonald. (Trans. A. I. M. E., Jan., 1909; 4 pp.) This chart is given to facilitate the work of the manager and shows diagrammatically the various labor departments, the number of class, and men employed, and the method of supervising each class.

8760—MEXICO—A Brief Review of the Mining Industry of Mexico. E. Ordonez. (Mexican Min. Journ., 1908; 11 pp.) A short discussion of the surface geology, veins and ore deposits in various parts of Mexico and a note on the evolution of the Mexican mining law. 60c.

8760a—MINE ACCOUNTING. J. G. Grant. (Can. Min. Journ., Feb. 15, 1909; 3 pp.) Shows procedure and form to be followed in organizing stock companies in Ontario. First article of series giving general principles of accounting. 20c.

8761—MINE SIGNALS—A Bell and Skip Recorder. J. Russell. (Journ. Transvaal Inst. Mech. Engrs., Nov. 1908; 1½ pp.) A description and illustration of an instrument for recording bell signals, time, the level or station and the speed of the winding engine. 80c.

8762—MINING SAFETY LAWS—Edward P. Buffet. (Eng. and Min. Journ., Jan. 6, 1909; 2 pp.) A short discussion of the laws in South Dakota, California, Washington and Kansas, relating to the safety of mines. Also a short note on the duty of mine inspectors. 20c.

8763—NEVADA in 1908. J. H. G. Wolf. (Min. and Sci. Press, Jan. 2, 1909; 3 pp.) A review of the mining industry in which the author takes up the various mining districts and concludes with a description of the attempt to rehabilitate the Virginia and Comstock mines. 20c.

8764—NEW ZEALAND as a Mining Country. James M. Bell. (Aust. Min. Stand., Nov. 25, 1908; 4½ pp.) A general description of the mineral resources of the country, together with a brief description of the principal gold and silver mines and the statistics of production. Kauri gum, schœelite, petroleum, iron, copper and some minor metals. Illustrated. 40c.

8765—NOVA SCOTIA—Minerals of Nova Scotia during 1908. A. S. Barnard. (Can. Min. Journ., Feb. 15, 1909; 2½ pp.) A review of the mining industry with statistics on the production of coal, gold, iron and gypsum and other minerals. 20c.

8766—PRODUCTION OF Silver, Copper, Lead and Zinc in the Central States in 1907. L. C. Graton and C. E. Siebenthal. (U. S. Geol. Surv., 1909; 65 pp.) This pamphlet is an extract from the Mineral Resources of the United States for the calendar year 1907, and gives statistics of the mine production of the metals enumerated.

8767—PROSPECT DRILLING in the Joplin District, Missouri. Doss Brittain. (Min. Wld., Feb. 13, 1909; 1 2/3 pp.) A discussion of churn drill operation, its efficiency and some notes on the cost of prospecting. 20c.

8767a—Prospecting—Successful Prospecting with Churn Drill Under Unfavorable Conditions. R. R. Sanderson. (Eng. and Min. Journ., Feb. 15, 1909; 1 pp.) Describes the advantages of gasoline operated churn drill used under conditions unfavorable for steam driven drills. 20c.

8768—REFRIGERATION as Practiced in Mining Operations. S. K. Patteson. (Min. Sci., Dec. 10, 1908; 2 pp.) A description of the methods employed in working through quicksand, mud or water by first freezing in the material. Illustrated. 20c.

8769—REVIEW OF MINING in Foreign Countries in 1908. D. E. Woodbridge, G. A. Ohren, A. Gray, O. Letcher, J. Plummer and J. Sammons and others. (Min. Wld., Jan. 30, 1909; 22 pp.) A review of the mining industry, with statistics of the output during 1908, in Mexico, Canada, South Africa, Australia, Korea, British India, Norway and Peru. 40c.

8770—REVIEW OF MINING in the United States in 1908. A. H. Brooks, E. E. Riechart, H. H. Martin, F. H. Hall, R. N. Bell, F. W. DeWolf, H. J. Stevens and others. (Min. Wld., Jan. 30, 1909; 42 pp.) A review of the mining industry for the year 1908 in Alaska, Arizona,

California, Colorado, Idaho, Illinois, Lake Superior District, Missouri, Kansas, Oklahoma, Montana, Nevada, New Mexico, Oregon, South Dakota, Utah, Wisconsin and Wyoming. 40c.

8771—REVIEW OF PROGRESS—Mining and Metallurgy in 1908. (Min. Journ., Dec. 28, 1908; 2½ pp.) Gives an account of a dull year in mining, together with brief notes on various mining districts in the world; also makes special mention of a number of new metallurgical processes. 40c.

8772—SHAFT SINKING—Method of Refrigeration in the Sinking of Shafts. S. K. Patteson. (Min. Wld., Dec. 5, 1908; 2 pp.) Description of method used in sinking a 400-ft. shaft through quicksand without the aid of pumps. Ammonia is compressed and circulated through expansion coils located in brine tanks and through hole holes surrounding the shaft. Illustrated. 20c.

8772a—SHAFT SINKING—Sinking of Wabana Submarine Slopes. R. E. and A. R. Chambers. (Can. Min. Journ., Feb. 15, 1909; 1½ pp.) Details the plant and working methods in exploiting the enormous ore fields under Conception Bay. Illustrated with plans and maps. 20c.

8773—SKETCH MAPPING in Southern Nigeria. L. H. L. Huddart. (Min. Journ., Dec. 19, 1908, and Jan. 9, 1909; 2 pp.) Deals with the general methods used in sketching an unexplored country, together with the methods of recognizing the faults that are encountered. Illustrated. 60c.

8774—SOUTH AFRICAN MINING INDUSTRY in 1908. (So. African Min. Journ., Jan. 2, 9, and 16, 1909; 3 pp.) A review of the review of the statistics of developments in the mining of gold, diamonds, coal and base metals. 80c.

8775—SOUTH AMERICA—Twenty-five Years of Mining. E. Ashmead. (Can. Journ., Nov. 1908; 2 pp.) A retrospective review, 1880-1904 of South American mining companies registered in Great Britain, with notes and comments and the names and capitals of the principal registrations. 40c.

8776—TIMBERING—An Improved Method of Timbering Workings. M. Schwerin. (Min. Wld., Feb. 6, 1909; 1 p.) Description of the author's patent No. 904,921, which was devised to minimize the cost of timbering and to reduce the cost of removing ore and waste. Illustrated. 20c.

8777—TIMBERS—Eucalyptus for Mine Timbers. L. W. Symmes. (Min. and Sci. Press, Dec. 26, 1908; 1 p.) A description of the wood of the eucalyptus, and tests as compared with other mine timbers. 20c.

8778—TOPOGRAPHIC ENGINEERING and Mining. W. B. Blackburn. (Mex. Min. Journ., Feb. 15, 1909; ¼ pp.) A discussion of the methods of mining, and interpretation of topographic maps. 20c.

8779—UNITED STATES—Mining in the United States During 1908. (Eng. and Min. Journ., Jan. 9, 1909; 23 pp.) History of the year in various camps of Colorado, California, Nevada, Montana, Utah, South Dakota, New Mexico and other States. A review of the progress and developments during the year. Illustrated. 20c.

8780—UTAH MINERAL DEPOSITS and Their Metallurgical Treatment. Robert H. Bradford. (Salt Lake Min. Rev., Dec. 30, 1908; 6 pp.) A general résumé of the mining industry for the year, together with a description of a number of the more important mining and metallurgical plants. Paper read before the Am. Min. Congress, Dec., 1908. 20c.

8781—VENTILATION—The Ventilation of Mines. IX. J. J. S. (Min. Stand., Nov. 1 and 18, 1908; 2½ pp.) A discussion of dust as the cause of lung diseases amongst the miners. A remedy suggested, also a short note on the sanitary condition of mines. Series concluded. 60c.

8782—VENTILATION of Mines. (Aust. Min. and Eng. Rev. Nov. 5, 1908; 3 pp.) A discussion of an Act of the Mines Department of Victoria relating to mine ventilation, in which is shown many improvements over previous systems. 40c.

8783—WASTE DISPOSAL—Conveyor System for Disposing of Waste. E. Higgins. (Eng. and Min. Journ., Jan. 23, 1909; 1 p.) Gives details of the construc-

tion and operation of the Dobbie conveyor, which is now in use at Ontario Center, N. Y., for stripping the overburden from iron ores. Illustrated. 20c.

8784—WINDING ROPE.—A. F. C. Kerr. (Students' Magazine, Ballarat School of Mines. Vol. XI, No. 1, 1908; 2 pp.) The author emphasizes the fact that ropes must be taken out of, and also gives formula for determining the size of rope to be used. 40c.

8785—WIRE ROPES.—The Flexibility of Wire Ropes. R. W. Chapman. (Aust. Min. Stand., Nov. 18, 1908; 1 p.) A few notes on measures of, and comparing the flexibility of ropes of various sizes. Illustrated. 40c.

ORE DRESSING—GENERAL

8786—MILLING COSTS.—R. S. Handy. (Min. and Sci. Press, Jan. 23, 1909; 3 pp.) The author gives a number of suggestions that might be applied for arriving at milling costs and efficiency. In this case they apply particularly to a lead-silver concentrator. Illustrated. 20c.

8787—SAMPLING BY MACHINE. T. R. Woodbridge. (Eng. and Min. Journ., Jan. 30, 1909; 3 pp.) A discussion of the advantages of machine sampling as compared with hand sampling. Illustrated. 20c.

METALLURGY—GENERAL

8788—CONVEYING MATERIALS.—The Elements of Chemical Engineering—III. (Chem. Eng., Jan., 1909; 6 pp.) The author discusses injectors, syphons, compressors, blowers and fans. Illustrated. 40c.

8789—ELECTROMETALLURGY.—Some Recent Advances in Electrochemistry and Electrometallurgy. S. Dushman. (Journ. of Elec. Power and Gas, Feb. 6, 1909; 2 pp.) A review of the early experiments in electrochemistry, and some notes on the fixation of atmospheric nitrogen, electric smelting, and the experiments in obtaining silicon monoxide by reducing silica at the temperature of the electric arc. 20c.

8790—REFRIGERATION.—The Uses of Mechanical Refrigeration in Metallurgical Practice. J. H. Hart. (Eng. Mag., Feb., 1909, 4 pp.) A discussion of mechanical refrigeration in the condensation of smelter fumes and in blast furnace operation. In the applications suggested by Dr. Hart the possible results in economy to the mining and metal industries are even larger than those appealing to the producers of refrigeration machinery.

8791—SMELTER WASTES.—Injury to Vegetation and Animal Life by Smelter Wastes. J. K. Haywood. (Bull. 113, U. S. Dept. of Agriculture, 1908; 40 pp.) Briefly reviews the process of extracting metals from ore and resultant waste, and gives the results of experimental and field investigations relating to the action of sulphur dioxide and sulphur dioxide fumes on vegetation; also investigations of injury to vegetation and animal life by smelter wastes around Anaconda, Mont. Illustrated.

8792—SMELTING.—The Behavior of Calcium Sulphate at Elevated Temperatures with Some Fluxes. H. O. Hofman and W. Moore. (Trans. A. I. M. E., Jan., 1909; 26 pp.) Gives the results of a series of experiments with both hydrous and anhydrous calcium sulphate with silica, ferric oxide, and lead oxide to show the behavior of calcium sulphate at high temperatures. Illustrated.

8793—TESTING.—Hallentine's Process of Testing the Hardness and Density of Metals. Wm. I. Ballentine. (Journ. Frank. Inst., Dec., 1908; 8 pp.) The report of the Franklin Institute through its Committee on Standards and the work on the above process of testing the hardness and density of metals and other materials. 60c.

8794—WELDING.—Oxy-Acetylene Welding and Cutting. H. R. Cobeigh. (Iron Age, Aug. 7, 1909; 5 1/2 pp.) The oxy-acetylene flame gives a temperature of about 6300 deg. F. This article gives a description of the torch used; the supply of the gases, and examples of typical work upon which the process has been tried. Also some notes on the cost. Illustrated. 20c.

MINING AND METALLURGICAL MACHINERY

8795—BELT CONVEYERS.—Capacity

of Belt Conveyers. R. W. Dull. (Min. Sci., Feb. 4, 1909; 1 p.) The author has constructed a chart which is based on good feeding conditions. The chart has curves for various kinds of material based on the belt speed which he recommends they should run for the particular kind of material. Illustrated. 20c.

8796—BLOWER.—The Rotary Blower in Smelting Works. G. C. Hicks, Jr. (Eng. and Min. Journ., Feb. 13, 1909; 3 1/2 pp.) A discussion of the principles of producing blast by means of rotating impellers; simplicity and efficiency of apparatus and the essentials of successful operation. Illustrated. 20c.

8797—BOILER PLANT.—Controlling the Coal Supply at Boiler Plants. G. A. Burrill. (West. Chem. and Met., Jan., 1909; 12 pp.) A discussion of the general considerations; physical and chemical conditions; analysis; sampling; contract specifications; and the requirements of the boiler plant. 80c.

8798—HAULAGE.—New Hauling Station, Great Boulder Mine, West Australia. (Aust. Min. Stand., Dec. 9, 1908; 1 1/2 pp.) This article is essentially a description of a steel galloway frame, together with the hoisting machinery and a short note on the Hadfield gyratory crusher. Illustrated. 40c.

8799—HOISTING.—Devices for Greasing Winding Ropes and Cage Guides. O. Döbelstein. (Coll. Guard, Jan. 29, 1909; 1 p.) A description of experiments which have been carried out at the Hugo colliery with an automatic greasing device operated by compressed air using ordinary engine oil. Illustrated. 40c.

8800—HYDRO-ELECTRIC POWER.—The Analysis of an Hydro-Electric Project. H. Von Schon. (Journ. West. Soc. Eng., Dec., 1908; 28 pp.) A comparison of power plant costs with the cost of hydroelectric power. A discussion of the advantages of water power and the investigation of its market. 40c.

8801—INDICATOR DIAGRAMS AND Vacuum Charts. W. R. Deggenhardt. (Monthly Journ., 1908; 9 p.) Chamber of Mines, Nov. 30, 1908; 9 p.) The author discusses indicator cards and their use for regularly recording the performances of mill engines and air compressors. Illustrated. 80c.

8802—MECHANICAL EQUIPMENT.—The Development of Medium Power for Haulage and Other Purposes About Mines During the Last Fifty Years. J. Unsworth. (Iron and Coal Tr. Rev., Nov. 27, 1908; 2 pp.) Abstract of paper before the Nat. Assn. of Colliery Managers. Deals with winding engines, mechanical power under ground haulage gears, steam and compressed air, pumping and electrical developments. 40c.

8803—MINE DRAINAGE.—With Special Reference to High Lift. Centrifugal Pumps. H. Kestner. (Journ. Trans. Inst. Mech. Engrs., Nov., 1908; 10 pp.) A mathematical discussion and formulae which can be employed for calculating the best speed of the water in the delivery pipes. Also a description of the construction of the pumps. Illustrated. 80c.

8804—OIL BURNING.—Unnecessary Losses in Firing Fuel Oil and an Automatic system for Eliminating Them. R. Weymouth. A. S. M. E., Nov. Dec., 1908; 23 pp.) Discusses the proper method of using fuel oil and points out certain precautions which tend to reduce unnecessary losses. The author outlines a complete system for burning oil. Illustrated.

8805—OIL BURNING PLANT.—Fuel Economy Tests at a Large Oil Burning Electrical Power Plant Having Steam Engine Prime Movers. R. Weymouth. A. S. M. E., Nov., 1908; 24 pp.) Gives the results of various fuel economy tests at the Redondo plant of the Pacific Light and Power Company near Los Angeles, Cal. Illustrated by curves and diagrams. 80c.

8806—OIL ENGINES. W. A. Tooke. (Mech. Wld., Nov. 20 and 27, 1908; 2 1/2 pp.) Gives the performances of several engines as shown by diagrams. Illustrated.

8807—ORE BUNKERS.—Construction and Method of Operation of Ore Bunkers at Skuwayn. A. I. Berdoe. (Can. Min. Inst., Jan., 1909; 6 pp.) The author gives a detailed description of the ore bunkers and illustrations showing their operation.

8808—ORE HANDLING MACHINERY.—Modern Ore Handling Machinery—III. Walter G. Stephan. (Iron Tr. Rev., Dec. 24, 1908; 3 1/2 pp.) Describes the recent installation of ore-handling machinery at the new ore and coal dock of the Pennsylvania railroad at Ashblake harbor on the southern shore of Lake Erie. Illustrated. 20c.

8809A—ORE HANDLING PLANT in New Caledonia. (Eng. and Min. Journ., Feb. 26, 1909; 5 pp.) Describes an elaborate system of suspension tracks and cable haulage comprising four main lines for carrying ore, coal, merchandise and passengers. Illustrated. 20c.

8809—SAFETY CATCH.—The Quest of the Safety Catch. (So. African Min. Journ., Jan. 16, 1909; 1 p.) Some notes on the results of the experiments made on the 7th of January, 1909, before the Government commission to determine the best type of safety catch. 40c.

8810—STEAM BOILER PRACTICE.—The Significance of Drafts in Steam Boiler Practice. W. T. Ray and H. Kreislinger. (Bull. 367, U. S. Geol. Surv., 1909; 60 pp.) This pamphlet contains the results of the experiments conducted by the survey at Norfolk, on the pressure drops of gases passing through furnaces; steaming tests at St. Louis, locomotive tests at Portsmouth, and some laboratory experiments relative to the flow of gases through boilers. Illustrated.

8811—TUNNELING MACHINE.—The Karns Tunneling Machine. A. B. Gresson. (Salt Lake Min. Rev., Jan. 15, 1909; 2 pp.) A short description of a 4 ft. tunneling machine which is now in operation at the India Gold Mining Company, Boulder, Colo. The experimental work done with this machine so far is very encouraging. Illustrated. 20c.

8812—WATER SOFTENING.—The Chemical Aspects of Impurities which Cause Scale and Corrosion in Steam Boilers. J. C. W. Greth. (Iron Tr. Rev., Feb. 4, 1909; 7 pp.) An abstract of a paper read before the Am. Inst. of Chem. Engrs. at the Pittsburgh 1908 meeting, in which the author discusses impurities in water and the means of removing them. Illustrated. 20c.

ANALYTICAL CHEMISTRY.

8813—ALLOY ANALYSIS.—New Methods of Alloy Analysis. W. B. Price. (Chem. Eng., Jan., 1909; 4 pp.) The author describes methods for the rapid determination of nickel in German silver, watch nickel and nickel alloys. 40c.

8814—TITRATION APPARATUS.—Improved Titration Apparatus. R. Kann. (West. Chem. and Met., Jan., 1909; 3 pp.) A description and a detailed drawing showing the apparatus used. 80c.

8815—VANADIC ACID.—The Iodometric Estimation of Vanadic Acid, Chromic Acid and Iron. (Trans. Am. Chem. Soc., Feb., 1909; 5 pp.) This paper shows that the processes of differential reduction may be extended to the estimation of three constituents: in the present case, vanadic acid, chromic acid and iron. 40c.

8816—WARWICKITE.—On the Analysis and Chemical Composition of the Mineral Warwickite. W. M. Bradley. (Am. Journ. of Sci., Feb., 1909; 6 pp.) A short historical review and description of Warwickite, together with a method of analysis. 40c.

INDUSTRIAL CHEMISTRY.

8817—NITRIC ACID.—The Electric Discharge and Production of Nitric Acid. Wm. Cramp and B. Hoyle. (Elec. Rev., Jan. 15, 1909; 2 pp.) This is a description of a process for the production of nitric acid which consists in boiling first in an electrical furnace, calcium carbide and then passing nitrogen over this material at red heat, the rest being the formation of cyanamide. Illustrated. 40c.

8818—REVIEW OF INORGANIC CHEMISTRY, 1908. J. H. Wood. (Journ. Am. Chem. Soc., Feb., 1909; 20 pp.) A review of the research work on radium; tonium; the study of feldspar as a possible source of potash for fertilizers; the chemical and metallurgical processes in the preparation of graphite for lubrication; a study of the absorptive power of metals for nitrogen, and the study of iron rust due to electrolytic action. 80c.

A Cracked Cylinder Repaired!

This diagram shows a crack 16 inches long, in a cross compound high pressure cylinder, that was perfectly repaired with Smooth-On. The crack was filled and

painted with Smooth-On and the patch was dished along the line of the crack to make a recess to hold sufficient cement. Then the patch was bolted on, forcing the Smooth-On into the crack, and the cylinder was as good as new.

Smooth-On Cements

are made for all purposes around the power plant. Applied as paint, paste or putty they are used for permanently repairing all kinds of cracks, leaks, blow holes, for patching, for making connections in steam or hydraulic work, etc.

Smooth-On expands when metallizing and, when hard, expands and contracts like iron. It has proved itself absolutely invaluable to hundreds of Engineers. LET US SEND YOU THE INSTRUCTION BOOK, FREE.

Handling Ore at Copper Queen Mines, Bisbee

Ore Is Hauled, in Cars with Automatic Couplers, by Electric Motors,
Hoisted in Skips and Loaded into Railroad Cars by Belt Conveyers

BY WALTER GARDNER*

The Copper Queen Consolidated Mining Company has recently introduced new methods of handling the ore at its mines at Bisbee, Arizona. Formerly, the small mine cars having a capacity of 13 cu.ft. were trammed by hand or hauled by mules to the shaft stations of the various mines, hoisted on two- or three-deck cages to the surface, and dumped into railroad

stead of hoisting the ore from each mine through its respective shaft, the entire output is hauled to a main hoisting shaft, the Sacramento, in trains drawn by electric locomotives. Electric haulage is installed on alternate levels beginning at the 400-ft. down to the 1200-ft. level, the levels being 100 ft. apart.

The ore from the stopes above the

swung back out of the way, permitting free use of a bar to pry loose the obstruction. On the haulage levels the ore is run into self-dumping, side-discharge cars of the "gable," or "A" bottom type, built by the Arthur Koppel Company. The body of the car is 4 ft. 8 in. by 2 ft. 6 in. by 2 ft. 9 in. deep, and has a capacity of 21 cu.ft. The over-all

FIG. 1. SKIP DUMPING AT SACRAMENTO SHAFT. FEED CHUTE TO CONVEYER SYSTEM ON LEFT

cars from elevated loading stations; all of this entailed a comparatively high labor cost. The present system includes electric haulage underground and the transfer of the ore to railroad cars by means of belt conveyers, thus reducing the rehandling of ore to a large extent by the substitution of mechanical methods for hand labor, though mule haulage and tramping are not entirely eliminated. In-

300-ft. level is drawn off into cars which are assembled into trains and drawn by mules to chutes, where the ore is dropped to loading stations on the 400-ft. level. From the 200-ft. main chutes extend directly to the 400-ft. level. The ore from stopes between the main haulage levels is handled in a similar way. All chutes are provided with gates of the arc type, made of $\frac{1}{4}$ -in. steel plate. These not only allow easy control of the flow of ore, but in case of clogging in the chute they may be

dimensions are 6 ft. 4 in. by 2 ft. 8 in. by 3 ft. 10 in. high. The gage of the wheels is 20 in. and the wheel base is 21 in., so that curves of 15 ft. radius can be passed. The couplings are of the automatic type.

At the main loading stations a double track and switches are provided. After loading, the cars are made up into trains; the length of the trains varies on the different levels, according to the conditions of grade, but the average haul is about 12 tons of ore to the train. The

*Mining engineer, P. O. Box 1055, Bisbee, Ariz.

trains are drawn to the Sacramento shaft by the Goodman electric locomotives at a speed of approximately six miles per hour. The over-all dimensions of the locomotives are 8 ft. by 2 ft. by 2 ft. 9 in. high; the wheel base is 24 in. The motor takes direct current at 250 volts from a trolley wire hung 6 ft. 6 in. above the center of the track. In untimbered workings the wire is suspended from 4x6-in. sprags; these are 3 ft. 6 in. long, supported by two 1-in. bolts let into the back of the drift and they are placed about 50 ft. apart in the straight drifts; around curves they are placed closer together to keep the wire in the center of the drift. The track is of 32-lb. steel laid on 4x6-in. ties; the rails are well bonded together

The hoist itself, built by the Nordberg Manufacturing Company, is of interest as it is the first of its type to be installed in the district. It is a tandem-compound, condensing, direct-acting hoist having 16x24x48-in. cylinders. The drums are 7 ft. in diameter and have 60-in. faces so that they are capable of carrying 2100 ft. of 1¼-in. round rope in two layers. The steam is generated in a central power house, situated nearby, from Stirling boilers equipped with Foster superheaters and Greene fuel economizers. It is at this power house that the electricity for the haulage system is generated. By means of rotary transformers the direct current for the mechanical traction is obtained by stepping down and transforming current

sists essentially of a cross conveyor delivering the ore to one of two loading conveyers; these latter belts are approximately at right angles to the first and run on a light steel trestle above and parallel to the railroad tracks. The cross conveyor is 240 ft. long; the loading conveyers are each 330 ft. long; all the belts are 30 in. wide and are driven by electric motors. The ore from the short link conveyor is fed by means of a suitable chute or spout to the cross conveyor, which carries the ore down to the railroad tracks, passing through the light building near the headframe shown in Figs. 1 and 2. This building is the scale house and contains a Blake-Dennison scale which automatically weighs and re-

FIG. 2. CONVEYER SYSTEM FOR LOADING ORE TRAINS AT COPPER QUEEN MINES

by copper wires. The least radius of curvature employed is 25 feet.

HANDLING THE ORE IN THE SHAFT

On the arrival of a train at the Sacramento shaft the side doors of the cars are released and the ore discharged into pockets below the station. The train of empties then returns to the main track by a loop passing around the shaft. These ore pockets, which have a capacity of 50 tons, terminate in two chutes for loading the skips in which the ore is hoisted through a vertical shaft to the surface. In order to prevent overloading, the proper amount of ore for one hoist is determined by means of a measuring box, placed below the ore pocket proper. The skips have a capacity of 60 cu.ft. and are self-dumping. They are built of ½-in. steel plate and were constructed at the company's machine shop.

at 2200 volts that is generated by Curtis vertical turbines. The economy of this central plant and of the type of hoist employed are large factors in reducing the cost of handling the ore, as the work of the simple, non-condensing hoists at the various shafts is now confined to hoisting and lowering men and timbers; the "dinky" hoists, formerly used for this purpose, are now unnecessary.

HANDLING THE ORE AT SURFACE

When hoisted to the surface, the skip automatically dumps its contents into a steel hopper at the base of the head frame (Fig. 1). The ore is carried from the hopper to the first of the belt conveyers by means of a short steel link conveyor, the drive of which is synchronized with the speed of the belt. As may be seen in the accompanying illustration (Fig. 3), the belt-conveyor system con-

siders the amount of ore carried by the belt. By means of a tripper the ore may be delivered at will to either of the two loading conveyers. The railroad cars, having a capacity of 50 tons each, are drawn up in trains of ten cars on either side of the belt, which discharges the ore into them by means of a tripper traveling along the belt. This tripper is self-reversing; as soon as it reaches the end of the conveyor it automatically stops and begins to travel in the opposite direction. The spaces between the cars are bridged by inclined spouts, so that no ore falls between. In this way the ore is evenly distributed over ten cars and the contents of the tenth car may be taken as a sample of the train load. Suitable provision is made for switching loaded cars and empties, and ample accommodation is made for further strings of cars while waiting to make up a train to carry the

ore to the smelter at Douglas. With a view to possible needs in the future, the belt-conveyer system, which was built by the Stephens-Adamson Manufacturing Company, is designed to handle 3000 tons per day, although the present output is considerably less than this amount.

Determination of Silver in Gold Bullion

E. H. Taylor (*Journ. Chamber of Mines of West Australia*, July 31, 1908), describes the method in use at the Great Boulder Perseverance Gold Mining Company, Ltd. mine for the determination of silver in gold bullion. The method involves the fusion of the bullion with metallic cadmium, solution of the fused alloy in nitric acid and titration of the silver in the solution with ammonium sulphocyanate. The method, although not a new one, does not seem to be generally known. The author claims that the amount of copper present in a bullion 900 fine in silver and gold does not in-

terfere with the delicacy of the end reaction. A standard solution of ammonium sulphocyanate is made by dissolving 1.6 grams of the pure salt in 1000 c.c. of distilled water. The solution is standardized against pure silver foil, 1 c.c., approximately, equaling 4.483 parts of silver per 1000. A check piece of bullion containing, approximately, the same amount of silver as that to be assayed, is fused with cadmium and treated in exactly the same manner as the assay.

A preliminary fire assay is first made to determine the amount of silver to be used for the check piece. Then 0.5 gram of the bullion is fused in a porcelain crucible with 1.5 grams of cadmium under a cover of potassium cyanide. The fusion period is about five minutes with an ordinary lamp during which time the cadmium must be completely covered with the cyanide. The fusion is allowed to cool, the cyanide dissolved away with a stream of running water, and the clean ball of alloy placed in a flask.

The alloy is covered with 20 c.c. of

Ore Treatment at the Giant Mine, Rhodesia

SPECIAL CORRESPONDENCE

In the November *Journal of the Chemical, Metallurgical and Mining Society of South Africa*, Reginald C. H. Cooke contributes an interesting description of the reduction plant at the Giant mine. The process used is remarkable, owing to the absence of a cyanide plant. The gold is caught by amalgamation and on blanket

The following table shows the different results obtained as $\frac{3}{8}$ -in. mesh, or $\frac{1}{2}$ -in. mesh is used. The difference between Nos. 1 and 2 is due to the position of the grizzlies, No. 2 battery receiving most of the fines.

	Battery No. 1, $\frac{3}{8}$ -in. Mesh Screening. Per Cent.	Battery No. 2, $\frac{1}{2}$ -in. Mesh Wire Screening. Per Cent.	Battery No. 3, $\frac{1}{2}$ -in. Mesh Screening. Per Cent.
+ $\frac{3}{4}$			3.12
+ $\frac{1}{2}$	2.50	0.62	7.22
+ $\frac{3}{8}$	7.38	5.62	10.22
+ $\frac{1}{4}$	6.15	5.00	8.00
+ 30	25.00	22.50	25.00
+ 60	12.50	13.78	12.45
+ 90	8.19	10.00	7.75
+ 120	5.00	5.62	5.21
+ 120	30.75	36.00	20.00
Total..	97.50	99.14	98.97

The pulp on leaving the tables flows through amalgam traps and then into a table-mill dewatering spitzkasten 4x4 ft. The coarse goes to tube mills which are 25 ft. long and 5 ft. in diameter, lined with silex blocks, which last 31 weeks. The discharge from the tube mill contains 87 per cent. less than 90 mesh.

FIG. 3. CONVEYER SYSTEM FOR LOADING CARS, COPPER QUEEN MINES, SHOWING THE TRIP

FIG. 4. ORE CAR WITH AUTOMATIC COUPLING, COPPER QUEEN MINES

terfere with the delicacy of the end reaction.

A standard solution of ammonium sulphocyanate is made by dissolving 1.6 grams of the pure salt in 1000 c.c. of distilled water. The solution is standardized against pure silver foil, 1 c.c., approximately, equaling 4.483 parts of silver per 1000. A check piece of bullion containing, approximately, the same amount of silver as that to be assayed, is fused with cadmium and treated in exactly the same manner as the assay.

A preliminary fire assay is first made to determine the amount of silver to be used for the check piece. Then 0.5 gram of the bullion is fused in a porcelain crucible with 1.5 grams of cadmium under a cover of potassium cyanide. The fusion period is about five minutes with an ordinary lamp during which time the cadmium must be completely covered with the cyanide. The fusion is allowed to cool, the cyanide dissolved away with a stream of running water, and the clean ball of alloy placed in a flask.

The alloy is covered with 20 c.c. of

and canvas tables. The ore is a heavily mineralized chlorite schist, intermixed with a good deal of ironstone and quartz, and the following is a representative analysis:

Iron as Fe ₂ O ₃	Per Cent. 18.04
Magnetite.....	14.04
Pyrite.....	14.64
Insoluble silica and silicates.....	46.04
Al ₂ O ₃	6.04
Total.....	98.6

Specific gravity = 3.1.

The gold is of two kinds, (a) bright yellow gold, 30 per cent.; (b) refractory, of rusty appearance.

A very coarse screen is used in the battery, and consequently a large tonnage is put through—about 15 tons per stamp per 24 hours. There are 15 stamps, each weighing 1250 lb. In two batteries $\frac{3}{8}$ -in. screening is used, and in the third $\frac{1}{2}$ -in. screening. The reason given why $\frac{1}{2}$ -in. screening is not used in all batteries is that the ore crushed would then exceed the capacity of a single tube mill. About 30 per cent. of the gold is caught on the plates which are 4 ft. long and which are not injuriously affected by the coarseness of the material passing over them.

The pulp from the tubes passes over blanket tables, consisting of 12 strakes—two of which are spares—12 ft. long by 2.5 ft. wide with a 12.5-per cent. fall. About 55 per cent. of the gold is recovered from the blankets, which are washed at short intervals, the frequent washing being considered an important feature. About 4 to 5 tons of concentrates are won per day, which are reconstructed on another blanket table until about half a ton of rich concentrate is obtained. This concentrate is treated in an amalgam barrel with about 300 c.c. of concentrated HNO₃. The acid cleans the gold and renders it amenable to amalgamation.

The total extraction averages 87 per cent., the tailings carrying about 1 dwt. The costs are about \$1.20 per ton, but may be reduced from 6c. to 12c. per ton.

For the year ended June 30, 1908, on a total of 65,068 tons worked, the costs of all departments were: Mining, \$1.24; milling, \$1.30; sorting and crushing, \$0.24; general charges, \$0.48; mine development, \$0.44; total, \$3.70 per ton.

Richards Pulsator Jig and Classifier

A New Principle in Ore Dressing, That of a Current of Water Pulsating Rapidly in a Single Direction, Applied to the Jig and the Classifier

BY FRANK E. SHEPARD*

Dr. Robert H. Richards, the eminent author of "Ore Dressing," has for many years conducted exhaustive experiments for the purpose of determining the action of ore particles in bodies or currents of water and the results of these investigations form the subjects of various papers in the *Transactions* of the A. I. M. E., *The Mineral Industry*, and many technical papers. Particular attention has been given to practical devices for improvement in the jigging of ores and the hydraulic classification of ore pulps, previous to concentration.

The climax of all this great work is embodied in two remarkable devices, one, the Richards pulsator jig for the concentration of the coarser ore particles, and a machine separate and distinct from the jig, known as the Richards pulsator classifier, which effects a hydraulic classification of the finer ore pulps, previous to wet concentration.

THE RICHARDS PULSATOR JIG

The field of the hydraulic jig is found in the concentration of ores in which the mineral occurs wholly or partially in comparatively coarse particles. For many years jigs have been most successful in the treatment of coarse products and they are also efficient in the concentration of fine pulps; they are sometimes, though rarely, used for slime products, but commercial practice seems to place the limit of the smallest advisable pulp particle for jig treatment at 1 mm., or about 12 mesh No. 19 wire.

Heretofore, jigs have been designed along two general lines: (1) Jigs with movable sieves, which produce the hydraulic currents by pushing the screen up and down in the water. (2) Jigs with fixed screens in which the hydraulic currents up and down through the screen are produced by a plunger, actuated by eccentrics, tappets or other mechanical equivalents.

In both these types of jig the concentration of the mineral portions of the ore is effected by an upward and downward current of water alternating with each other and acting upon a bed of the ore particles supported on a wire screen, having openings depending on the size of the ore particles treated. During the upward movement of the water called "pulsion," through the screen aperture, the various

ore particles arrange themselves according to their specific gravities, those of greater specific gravity arranging themselves in the lower strata just above the screen, while the particles of lesser specific gravity are found in the upper strata, farthest from the screen. During the downward movement of the water called "suction," ore particles possessing a greater specific gravity are drawn downward through larger particles toward and sometimes through the screen.

The valuable mineral portions of the ore are usually of a high specific gravity and thus settle down on the jig screen and are sometimes drawn off from above the screen by means of a device known as a "cup discharge," or under certain conditions are drawn down through the jig screen into that portion of the machine known as the "hutch," and giving a concentrated product called the "hutch" product. The tailings, or ore particles containing little or no value, being of less specific gravity, are found in the upper strata, most remote from the jig screen, and by various designs of gates are discharged from the jig.

This suction portion of the water current, while serving as a benefit under certain conditions, proves a serious defect in the successful continuous operation of the jig, on account of the "blinding" of the jig screen, caused by ore particles being drawn into the screen opening during the suction cycle of the water current. This suction also tends to pack tightly the layers of high specific gravity just above the screen, and thus tends to prevent a free arrangement of the ore particles, which is absolutely necessary for a best possible separation of concentrates from tailings.

The jig most generally used in the concentration plants of the world is of the fixed-screen type, known as the Harz jig. The Richards jig has its feed box, screen compartments, concentrates discharge and tailings spout in the same relative positions as found in the Harz jig; it has a hutch for each compartment, of the same general design as found in the Harz; the water current enters the hutch in the same general direction, and, generally speaking, the principles employed in the Harz jig are found in the Richards jig. The distinguishing feature of the Richards jig is in the novel application of a pulsating water current, first applied successfully by Doctor Richards. The hydraulic water is delivered to the jig under a head of about 30 ft., and passes to a special design of rotating valve, which is balanced in all positions. This valve is driven by a 3-in.

belt and pulley from any suitable mill shaft which has a fairly constant speed. The shaft driving the concentrating tables will serve. The valve is usually driven at the rate of from 75 to 150 r.p.m., and being double-ported, delivers a water current of from 150 to 300 intermittent pulsations per minute. An air chamber is used in connection with the rotating valve and serves to intensify the action of the water current in the jig. This pulsating current of water is delivered to a manifold equipped with suitable adjustable valves, which serve to increase or diminish the intensity of hydraulic water in any one compartment. Thus we have an intermittent pulsating current of water passing up through the screen in each compartment, and not being drawn down through the screen again, as in the Harz jig.

EFFECT OF THE PULSATING CURRENT

The effect of this pulsating water current in the treatment of ores in the Richards jig is most remarkable. The four-compartment jig has four compartments, each having a screen area 4x4 in., making a total jigging screen area of 64 sq.in. A jig of this size and type treated Butte copper ores, previously screensized through 8-mm. and on 2½-mm. screens, at the rate of 90 tons per 24 hours; the quality of concentrates and tailings meeting the requirements of the system. To accomplish equivalent results with the common Harz jigs would require three double four-compartment Harz jigs having a total screen area of 12,000 sq.in., as compared with 64 sq.in. in the Richards jig; or 1 sq.in. in the Richards system does as much work as about 200 sq.in. in the Harz system.

Following out the comparison we have the following parts requiring attention and lubrication in the Harz system for the tonnage quoted: 6 tight pulleys, 6 loose pulleys, 30 babitted bearings, 24 eccentrics and straps, or 60 places to lubricate as against one pulley and two bearings in the Richards jig.

A most important discovery in the development of the Richards jig was found in the small amount of fresh water required. The average amount of water required in the Harz system of jigging, as determined from 30 mills in American practice, is 4700 gal. per ton of ore treated. The average amount of water required in the Richards system is only 1000 gal. per ton of ore treated; furthermore, of this 1000 gal. of water delivered to the jig, 500 gal. of perfectly clear water

*NOTE.—From *Proc. Colo. Sci. Soc.*, Vol. IX. A description of these machines and the methods of operation appeared in the *JOURNAL* of Sept. 26, 1908.

*Mechanical engineer, Denver, Colo.

is discharged with the concentrates and may be returned for use in the mill system. In the Harz jig pulp beds of only 3 or 4 in. depth above the screens are maintained and the layer of concentrates is but 1 in. and often less; while in the Richards jig, ore beds of 12 and 14 in. are maintained and the layer of concentrates is 8 or 9 in. in depth. This greatly increased thickness of the concentrates bed acts as a filter and the water discharged with the concentrates is perfectly clear.

The feature of being able to carry such a deep bed of ore renders the operation of the Richards jig less subject to fluctuations in the ore feed, and having been suitably adjusted for a certain class of ore, the jig will operate hour by hour without any change of adjustment.

In jigs, using the pulsion and suction type of water current, large screen areas are necessary and in many cases artificial beds are required to treat the ores successfully. These large screen areas and the repeated grinding action of the mineral particles in the artificial beds or on the screen wires produces an abnormal amount of rich slimes, which greatly hinders, if it does not absolutely prevent, a successful recovery. In the Richards jig, no artificial bed is required; the jig makes it own bed; and further, there is not any passage of concentrates down through the screen into the hutch, the concentrates being discharged through a gate above the screen. The rapid action, the small screen areas, and the attrition reduced to a minimum, are reasons for reducing the slime losses in the Richards jig, and the sharp edges of the concentrates are a marked contrast to the same product from jigs of large screen areas with hutch products.

FIELD OF OPERATION

The field of operation for this Richards jig will be the treatment of any possible jigging ores in any screen-sized product from $\frac{1}{2}$ in., possibly as large as 1 in., down to $\frac{1}{32}$ in. in diameter. Commercial practice seems to place the lower limit of jig feed sizes at 1 mm., corresponding to about 12-mesh No. 19 wire. Any mill pulps finer than this may better be treated on shaking tables or belt vanners, if properly classified previous to concentration.

Two and three mineral separations may be made under reasonable conditions of jigging. Recent tests have proved that the Richards jig will successfully separate slate and refuse from good coal, which fact opens a wide field of operation, with great possibilities in a marked saving in clean coal, as well as a great improvement in the cokes manufactured from washed coal. Tests made at the Government coal-testing plant, on Illinois and local bituminous coals, indicate that the 4-in. four-compartment size will

treat such coal at the rate of 70 tons in 24 hours.

Statistics show that of the refuse thrown away in prevailing coal-jigging methods, from 10 to 50 per cent. is good coal. Tests made on the Richards jig indicate that a loss of good coal in the refuse of less than 5 per cent. may be realized.

This system of concentration for coarse ore products has developed not only a remarkable efficiency in the jigging system itself, but has created great possibilities in the economy of attendance, size of plant, power and water required. The Richards jig has been found to be automatic under working conditions and even with an irregular feed will still continue to deliver for hours a satisfactory product without any change in adjustment.

CAPACITY

The 4-in. four-compartment Richards jig, when treating Butte copper ores, carrying from 2.5 to 3.5 per cent. copper, recovered 37 per cent. of the copper in the feed at the rate of 90 tons in 24 hours. The concentrates are of a grade suitable for delivery to the copper smelter; the tailings are reground for subsequent table and vanner work. This means that 1 sq.in. of screen surface in the Richards system treats 1.4 tons of ore in 24 hours.

Reports of a 4-in., six-compartment Richards jig operating in Rico, Colo., on a difficult ore composed of galena, iron sulphides and zinc blende, gave a lead product of 76.7 per cent. lead, with only 3 per cent. zinc.

A 4-in., four-compartment Richards jig operating commercially on a lead ore carrying about 10 per cent. in the crude, in Boulder county, delivered a 60-per cent. lead product.

Numerous tests have been made on a 2-in., four-compartment Richards jig at the testing plant of Henry E. Wood & Co., Denver, Colo., and the results from a great variety of ores prove that good commercial results may be accomplished on this laboratory size, having only 16 sq.in. of screen surface.

THE RICHARDS PULSATOR CLASSIFIER

Following the concentration of coarse ore products by jigs, is the recrushing of the jig tailings and often the jig middling products by means of rolls, stamps, tube or roller mills. Various forms of hydraulic classifiers have been used to grade these recrushed pulps into different classes previous to their being delivered to tables or vanners, but the results have been far from satisfactory. In cyanide systems it becomes necessary to make a good separation of slimes from sands, and in tube milling the delivered product is usually classified previous to being delivered to the leaching or agitation systems. A study of Doctor Richards' "Ore Dressing" will

show the types of hydraulic classifiers which were designed in the long search for a successful system and the argument for classification previous to table and vanner work is ably presented in Doctor Richards' paper entitled "The Wilfley Table," *Trans., A. I. M. E.*, 1907 and 1908. Even now we find advocates of a mixed feed for good concentrating table work, and it is difficult to understand how such practice prevails, when test after test shows marked advantages due to a proper grading of ore pulps before table work.

The Richards pulsator classifier overcomes the difficulties found in the older forms of hydraulic classifiers and delivers a quality of pulps to tables which not only admits of greatly increased capacity, but improves the quality of work performed. Screen-sized pulps show a great improvement in table or vanner work when compared with an untreated or mixed feed, but there are so many mechanical difficulties attending the use of fine screens that the maintenance of such a plant becomes a serious factor in milling operations.

In the Richards classifier, the mechanical moving parts have been reduced to a minimum and the adjustments are simple, while the saving in space occupied is a marked advantage. The classifier consists of six compartments, all 4 in. wide and varying in length. This classifier delivers six graded pulps varying from the finest, which issues from the first and highest discharge gate, to the coarsest grade which issues from the last and lowest discharge gate. The same types of pulsating valve, air chamber, manifold, adjustable water valves and hutch are found as in the Richards pulsator jig.

Nearly all the old forms of hydraulic classifiers are modifications of the Rittenger type, called spitzkasten, in which classification is accomplished by a change in the velocity of the current of water carrying the ore. The pulp is fed to the first compartment, an inverted pyramid, having the smallest cross-section. The first compartment has a sectional area much larger than the launder delivering the pulp, hence the velocity of water current is reduced, with the result that the heavier particles of ore settle to the bottom of the compartment, where they are drawn off for treatment. The succeeding compartments of the classifier have a greater and greater cross-section, hence there is accomplished a further decrease in water currents with a resulting settling of finer and finer ore particles until the finest slimes pass out of the last compartment. The pulps delivered by these various compartments consist of small particles of mineral and larger particles of gangue material, equal-falling particles in water and diameters depending on the specific gravity of the particle. For example, a particle of galena 1 mm. in diameter falls in water with a quartz particle whose diameter is $\frac{3}{4}$ mm. If a concentrating table were fed with such classified pulps the result would be

a great improvement over the mixed feed, but the form of the spitzkasten is such that eddy currents are set up and the discharge of the partially classified pulp establishes more currents and the result is that fine slimes are delivered with the coarse pulps.

In screen sizing the attempt is made to deliver mineral and gangue particles of the same diameter or cube. But here again through imperfect washing, or insufficient screen area, a large proportion of slimes is delivered with the coarse pulps.

The Richards classifier is so designed and operated that the fine slimes are delivered from the first one or two discharge gates, leaving the coarse pulps clean and free from fine slimes to discharge upon the concentrating tables with practically clear water. It is often possible to catch from the last discharge gate a sample of pulp which will settle to the bottom of the sample dish, leaving the water clear.

ADVANTAGE OF CLASSIFICATION

If for purposes of illustration we assume fed to the Richards classifier a simple ore composed of galena and quartz, all the discharge gates will deliver a product in which the galena particle is one unit in diameter, while the diameter of the quartz particle issuing from the same compartment, will be $6\frac{1}{2}$ times that of the galena particle. The first compartment will discharge the fine slimes and the last, or sixth compartment, will discharge the coarsest particles, but from every compartment the quartz particle is $6\frac{1}{2}$ times the diameter of the accompanying galena particle.

Suppose these pulps are fed to any of the well known concentrating tables or vanners—with the pulps from the old form of classifier known as spitzkasten, the small diameter of mineral particle lies on the table surface in the lower strata of wash water, where the velocity of wash water is the least, owing to its retardation due to friction between the water and the table surface. The quartz particle being $3\frac{1}{2}$ times the diameter of the galena particle, projects farther up into the stream of wash water where the velocity of water current is greater; the quartz particle also presents an exposed area of more than 12 times the exposed area of the galena particle; consequently the quartz particle is washed down with the water current, leaving the galena particle to travel on to the concentrates box. Unfortunately the spitzkasten delivers with the coarse pulps, a slime product which does not belong with the coarse pulp, and the result is that a wash-water current suitable for the coarse mineral particle will be too violent for the slime particle and the slime value is washed away with the tailings and lost.

Suppose a screen-sized pulp is delivered to the concentrates surface. The mineral particle is the same diameter as the

gangue particle; they both project up into the wash-water stream the same vertical distance; the areas exposed to the wash water are the same, and we have only one property, the greater weight of the mineral particle, which tends to retard it and allow the gangue particle to wash away to the tailings discharge. It is easy to comprehend how the classified product, with its small particle of mineral and its large diameter of gangue particle will produce a more positive separation.

Now suppose we deliver the pulp from the Richards classifier, the product from which gives, for example, a galena particle one diameter and a quartz particle $6\frac{1}{2}$ diameters; then we have a quartz particle with an exposed area 42 times the exposed area of the galena particle. Note that the ratio between the diameters of galena and quartz particles of the pulp delivered by the old form of spitzkasten is 1 to $3\frac{1}{2}$; whereas the ratio between the diameters of galena and quartz particles of the pulp delivered by the Richards classifier is 1 to $6\frac{1}{2}$. In other words, the quartz particle delivered by the Richards classifier is nearly twice the diameter of the quartz particle delivered by the old form of spitzkasten, and presents more than three times the exposed area to the current of wash water.

PRACTICAL RESULTS

This very important point of increasing the ratio of equal settling grains allows a most interesting use of fine screens as concentrators. The Richards pulsator classifier makes it possible to select a screen of such opening that the mineral particle will fall through the screen, thus making a concentrate, while the larger gangue particle passes off as tailings. Sometimes a middling product is produced from Richards classifier pulps which carries large mineral particles and small gangue particles. In this case the screen may be selected to deliver the mineral as an oversize, while the gangue particle being smaller, drops through the screen. Both the results mentioned have been accomplished in actual milling operations.

Heretofore it has been considered that concentrating tables should not treat pulps coarser than 1 mm. or about 12-mesh No. 19 wire. In one instance a copper-ore pulp as coarse as 2.5 mm. was successfully treated on a concentrating table, with greatly increased capacity and improvement in quality of work as compared with former methods. It is not advisable, however, to treat a pulp as coarse as this on shaking tables, on account of the increased wear of the table surface.

The maximum capacity of the 4-in., six-compartment Richards classifier when treating thickened pulps is, from present knowledge, 180 tons per 24 hours for copper ores and 200 tons per 24 hours for lead ores. The fresh water required is from 1000 to 1200 gal. per ton of ore

treated. With a regular rate of feed the adjustments are very seldom changed and the classifier requires no more attention than may be given in the regular rounds of the millman.

Keeping Engine-room Reports Clean

In engine-rooms it is difficult to keep the reports of the daily run clean unless some provision is made to protect the report from becoming smeared with dirt and oil, and so rendered unfit for filing. The desk described by C. L. Greer shown in the accompanying illustrations, taken from *Power*, Nov., 1908, is a handy means of protecting such entry sheets. It consists

of a roller, A, large enough to carry the report sheet and an ordinary desk, the top of which is hinged at D and which has a slot in the top under which the roller with the report is placed in slotted bearings in the side of the desk. The slot is made narrow so that the top of the desk prevents the hand from touching the paper. The space below the roller can be used for extra report sheets and charts.

The present weight of the Philippine silver peso is 308.64 grains, 800 fine. The minor silver coins—50, 20 and 10 centavos are respectively one-half, one-fifth and one-tenth the weight of the peso, but are 750 fine. The peso first authorized was 416 grains, 900 fine, but it was found that these coins were exported to China for their silver value. To retain the coins in the Philippines it was necessary to reduce their bullion value. The peso contains 246.0 grains fine silver, or about two-thirds as much as the United States silver dollar.

Ontario Mines and Iron Deposits

SPECIAL CORRESPONDENCE

The latest report* issued by the Ontario Bureau of Mines opens with a comprehensive statistical review of the mining and metallurgical industries of Ontario in 1907, the details of which have already been given. The revised figures, however, show some changes, principally under the head of nonmetallic products, bringing the aggregate value of the year's output up to \$25,019,373 in place of \$24,697,775, as previously stated. This, as compared with \$22,388,383, the total for 1906, shows an increase of 12 per cent. In accordance with the practice recently adopted, to admit of a fair comparison between the mineral production of Ontario and that of other provinces where a different method of computing values has been used, the report contains another table showing the production on the basis of the value of the refined metals—the first figures presented being the values at the mines or as smelter products. By this method of computation the "refined value" of the metallic products is given at \$28,213,934, which with the nonmetallic values—\$10,468,538—makes a total of \$38,682,472 for the year.

ONTARIO MINE OPERATIONS

E. T. Corkill, provincial mine inspector, furnishes a report on the mines of Ontario, with detailed descriptions of the operations and condition of the principal gold, iron, copper-nickel and other mines; the mines of the Cobalt district being dealt with in another publication. Arthur L. Parsons treats of the geology of the portion of Thunder Bay district adjacent to the Algoma boundary, his contribution being of scientific rather than practical interest.

THE NIPIGON IRON RANGES

The iron ranges east of lake Nipigon are described in two reports, one by Prof. A. P. Coleman assisted by E. S. Moore, and the other by E. S. Moore. The first deals with the ranges in the Poplar Lodge and lake Wendigokan districts. Practically all the iron formation extending from Poplar Lodge, on the shore of lake Nipigon to lake Wawang, 21 miles inland, has been taken up in claims with the exception of a few breaks and a band of diabase which cuts across the range about 7 miles from lake Nipigon. The earlier found of the iron range outcrops were along the shores of lake Nipigon, where a northern, a southern and a central range were located. The Northern range has a length of about a 1¼ miles running northeastward. It reaches in one

place a width of 240 ft. but is seldom more than 50 ft. wide. Both magnetite and hematite occur but the range is too narrow and lean from the admixture of silica and slate to be very promising. The Central range lies 3 miles south of the Northern, and is first seen 1½ miles inland from Poplar Lodge. That part of the region is mostly covered with sand plains and swamp, so that the solid rock does not crop out frequently rendering it difficult to prospect without doing much stripping. A good deal of work has been done in this way, and three diamond-drill holes put down, but undoubtedly much of the range remains covered. The range has a length of nearly 3 miles with a breadth of about ¾ mile in the widest part. There are four known outcrops, one of which has been thoroughly prospected showing a widespread series of bands of iron foundation over a length of ½ mile and a breadth of ¼ mile. The ore is entirely hematite and the associated silica is jasper, often bright red. The Southern range has a length of 7 miles, including interruptions of drift and barren rock, and its greatest width is 500 ft. though generally not more than one-tenth as wide. It is separated from the nearest point of the Central range by ¾ mile of greenstone and schist. This range contains much magnetite and resembles the Northern range, though more extensive and richer in iron. For some miles eastward of the diabase hills which separate these ranges from those farther inland, it is no longer possible to distinguish three ranges. The more important outcrops occur west of lake Wendigokan, and southeast of it near Still lake. In the western area the iron formation is wide and consists of banded jasper and gray slate, but there is much schist in portions of the range. The length exposed is about ½ mile. The Still Lake area is a little shorter, but has a width of 450 ft. in the middle, part of it, however, being hidden by drift. The iron range is here very silicious, the last assays of samples running from 35.75 to 36.86 per cent. of iron. Farther to the east are two narrow parallel bands of the iron formation, the longer of which runs from the northeast end of Watson lake for nearly 2 miles with a maximum width of about 100 ft. The iron-bearing rock consists of magnetite and jasper with green slaty schist on each side. The richest specimen of magnetite collected from it runs 48.9 per cent. iron. The general character of these outcrops resembles those of the Northern and Southern ranges near Poplar Lodge, always containing more or less magnetite, yet with some hematite and jasper. The materials of the iron formation in the Nipigon region are always silica in some form, and an oxide of iron, magnetite or hematite, never siderite nor sulphides as in the Michipicoten region. There are two types of the formation, one consisting of interbanded quartzite or cherty silica with magnetite, the other of

jasper with hematite, but there are mixtures of the two in many places.

THE ONAMAN IRON RANGES

E. S. Moore's report deals with the Onaman iron ranges, occurring in the vicinity of the Hight of Land east of lake Nipigon near the headwaters of Johnson creek and Red Paint river. Little was known concerning the geology of this region until survey parties for the Transcontinental railway began work through northern Ontario, and a number of prospectors entered the field. During 1906 a considerable iron range was located for R. H. Flaherty, whose success attracted others, most of whom were unsuccessful. There are two distinct iron ranges and some scattered outcrops of the iron formation in this region. One of these ranges extends from the twelfth portage on the Red Paint river eastward across the Hight of Land and down Johnson creek for a distance of about 6 miles. The range is not represented by continuous outcrops, and the strike of the formation in different places varies on account of irregularities in the folding of the sedimentary rocks, caused by the massive igneous rocks associated with them. Since the iron formation lacks the great troughs formed by folding of thick strata of sedimentary rocks, it will probably prove shallower here than in other regions where schistose and sedimentary rocks are abundant. There seems to be one syncline extending along the north side of the range on the Miller claims. If any ore is found in this range it may be looked for in this syncline and a short distance north of the southern edge of the range.

The other range occurs between 2 and 3 miles south of the first, running nearly parallel to it. It has not been traced to its limits, but it is exposed for 2 miles and then runs into a swamp, where its extension can be followed by means of the dip needle. The rocks and iron-bearing minerals of the formation in these ranges are slate, green schists, jaspilite, specular hematite, magnetite and silica. The report gives an account of some of the development work done on the ranges and isolated outcrops, but so far the discoveries appear to have been of slight commercial value. On the Bain claims, about three miles south of the Hight of Land portage, stripping and trenching have disclosed a formation having magnetite and specular hematite contents, which in some cases form a sufficient percentage to make low-grade ore.

THE IRON AND STEEL INDUSTRY

The concluding portion of the volume consists of a paper by George C. Mackenzie on the "Iron and Steel Industry of Ontario," giving a large amount of statistical information both as to the mining and metallurgical departments, with data as to the iron ores and producing mines, which will be found comprehensive and

*"Seventeenth Annual Report of the Ontario Bureau of Mines, 1908." By Thomas W. Gibson, Deputy Minister of Mines. Pp. 356; Illustrated: 9½x6¾ in., paper, Toronto, 1908; Government Printing Office.

valuable. The problem of the magnetic concentration of iron ores is dealt with at length, and descriptions are furnished of the best known and most successful types of magnetic separators. In the course of his investigations the writer visited a number of large plants in the United States, obtaining at first hand information as to the methods of magnetic concentration in operation. In order to show that low-grade Ontario magnetites are amenable to concentration by means of the electromagnet, and with the view of ascertaining the per cent. of separation efficiency that might be expected in actual commercial operation, samples of ore were obtained from various localities in the province and submitted to preliminary testing in the mining laboratory of the Kingston School of Mines. The tests do not appear to have been conclusive, some of the ores requiring finer grinding than that to which they were subjected, but the results pointed to the conclusion that the concentrates obtained from the ores experimented with would require either nodulizing or briquetting before they could be used for smelting purposes. An elaborate description of the iron and steel plants of Ontario and the various processes in vogue is given.

The Rare Metals X—Zirconium

BY CHARLES BASKERVILLE*

Zirconium is allied to titanium and is rather widely diffused in igneous rocks. Zirconium compounds are almost always present in nepheline syenites.

ZIRCONIUM MINERALS.

	Zirconia Content.
Zircon, zirconium silicate.	61-67%
1. Compound zircons:	
(a) Eudialyte, a complex zirconium silicate.	11-17%
(b) Eucoelite, a complex zirconium silicate.	12-16%
(c) Polyminnite, a niobate and zirconate of cerium, etc.	30%
2. Gem varieties:	
(a) Azoelite, zirconium silicate.	64%
(b) Hyacinth, zirconium silicate.	64%
(c) Zirconites, zirconium silicate.	61-67%
(d) Jargons, zirconium silicate.	64-66%
3. Altered zircons:	
(a) Cyrtolite, containing yttrium earths, etc.	41-67%
(b) Aenderbergite, related to cyrtolite.	41-42%
(c) Malacoe containing various metallic oxides.	60-63%
(d) Tachyphalinite, containing rare earths.	40%
(e) Oerstedite, containing titania, etc.	69%
(f) Auerbachite, almost pure silicate.	55%
(g) Alvite, containing large amounts of yttria.	4%
Rosenbuschite, a complex silicate.	20%
Lavenite, a silico-zirconate of iron, manganese, etc.	29-32%
Titanite, a silico-zirconate of calcium and sodium.	16-23%
Hydrallite, a silico-zirconate containing fluorine.	22%
Catapleite, a hydrous silico-zirconate of calcium, etc.	30-40%
Elpidite, a hydrous sodium zirconium silicate.	20%

*Professor of chemistry, College of the City of New York.

Arrhenite, a heterogeneous decomposition-product.	3-4%
Sipyleite, a niobate of erbium, cerium metals, etc.	2-3%
Zirkelite, a complex zirconate.	53%
Baddeleyite, zircon dioxide.	96-97%
Tritonite, a fluo-silicate of thorium, cerium, etc.	1-2%
Erdmannite, a mixture of homillite and another mineral.	0-5%
Cerholmite, an altered homillite.	2-4%

Zirconia is extracted from zircon, which is mined in large quantities for technical purposes in North Carolina, especially near Green river, Henderson county. Cyrtolite is abundant in Rarering Hill, Llano county, Texas, and the deposits await development.

Zirconia possesses great radiating power and is very refractory. Cylinders of zirconia have been used in the Drummond light instead of lime and magnesia cylinders, and zirconia is in demand for producing refractory compounds suitable for incandescent illumination. With thorium and yttrium, zirconium enters into the manufacture of Nernst lamps, and filaments of zirconium are used in "Zirconium lamps." Zirconia yields with alizarin a color like one produced by chromium material. The use of zirconium nitrate as a food preservative has been patented.

Various zircons are classed among the gems; they often possess beauty and splendor. Transparent, red and brown varieties of zircon are cut and sold under the name hyacinth.

The market is well supplied with zirconium compounds at present.

ZIRCON

Zircon occurs in square prisms and pyramids, also in irregular forms and grains. It is found in crystalline rocks, especially granular limestone, chloritic schists, gneiss, syenite; also in granite, iron-ore beds, and alluvial deposits. It is one of the earliest minerals to crystallize from the cooling magmas, and the first one among silicates. The luster of zircon is adamantine and the color is colorless, grayish, yellowish, or brown. Its hardness is 7.5, and the specific gravity is from 4.2-4.86. It is brittle, and the streak is white. Zircon usually contains a small percentage of ferric oxide.

Before the blowpipe zircon is infusible, but the red varieties become colorless and the dark-colored varieties are rendered white; some specimens glow and increase in density on ignition. It is not acted upon by salt of phosphorus. Pulverized zircon is decomposed when fused with soda on the platinum wire, and the product gives the orange color characteristic of zirconia when tested with turmeric paper in a dilute hydrochloric acid solution. Zircon dissolves with difficulty in borax to a clear glass. It is insoluble in acids.

As mentioned above, zircons are especially abundant in Henderson county, N. C. Other specimen localities are: Maine, Vermont, Connecticut, New York, New Jersey, Pennsylvania, Colorado and

California. Eudialyte and eucoelite occur in Arkansas.

BADDELEYITE

Baddeleyite is found associated with magnetite, apatite, perovskite, ilmenite, microlite, and zircon in Ceylon and Brazil. It is of variable color, being from colorless to yellow, brown, and finally black, and has a vitreous luster. Its hardness is 6.5, and the specific gravity is 5.5-6.02. The streak is brownish white, sometimes white.

Baddeleyite is infusible, but glows brightly. It reacts faintly for iron with borax. It is insoluble in acids, and is only slightly decomposed by sulphuric acid in the powdered form. It is decomposed by fusion with acid potassium sulphate.

EUDIALYTE

Eudialyte occurs in tabular and prismatic crystals, also massive and sometimes reniform. Its luster is vitreous, and the color is rose-red, bluish red, brownish red, or chestnut-brown. It is brittle, and the streak is uncolored. The hardness is 5.5-5, and the specific gravity is 2.92.

Eudialyte yields a little water in the matrass. Before the blowpipe it fuses to a greenish gray bead, and gives an intense yellow flame. It is dissolved by borax to a clear glass which shows a little iron. It is easily decomposed by salt of phosphorus; and when oxide of copper is added a chloride of copper flame results. With hydrochloric acid it gelatinizes, and the dilute acid solution imparts a deep orange color to turmeric paper even after the iron in solution has been reduced to colorless chloride by boiling with metallic tin.

Indian Gold Mines

The mines of the Kolar goldfield in Mysore produced 45,314 oz. bullion in January, showing a decrease of 5360 oz. from December, but a gain of 1,411 oz. over January, 1907. The bullion reported this year was equal to \$842,985, or 40,783 oz. fine gold.

The production of two mines outside the Kolar field—Hutti Nizam's in the Deccan and Dharwar Reefs—was 1717 oz. gold in January, which compares with 1735 oz. in December. The output of these mines for the year 1908 was 21,215 oz. gold against 17,406 oz. in the preceding year.

Safety-catch devices that depend upon their action on the guides for gradually stopping the cage, according to *South African Min. Journ.*, Jan. 10, 1908, have been proved by experiment to be failures because of variations in dimensions of the guides, difference of condition of the timber in the guides, and the loss of equilibrium caused by inequality of brake action on the guides due to these causes.

Ways of Improving Piston and Hammer Drills

Efficiency in Piston Drills Can Be Increased by Using Heavier Steel, a Shorter and Quicker Stroke, Better Lubrication and Improved Chucks

BY EUSTACE M. WESTON*

This paper contains several extracts from my reply to the discussion on my paper "Notes on Small Stope Drills" read before the Chemical, Metallurgical and Mining Society of South Africa, but I have added some new matter and, through the courtesy of Mr. Mauss, its inventor, a description of the Konomax automatic piston drill. In my paper I raised the query as to what in machine drilling is the best ratio of foot-pounds of energy to an inch width of the cutting bit. The South African mines stope-drill contest, an account of

of the hole drilled, and it will be seen that the most powerful machines benefit most. By looking at Tables I and II it will be seen that most of the value of the results of this test as published was lost for comparing the boring speeds of hammer and piston drills owing to a misunderstanding of some sort as to the sizes of bits to be used and the distance to be bored by each bit. Table II shows this clearly, when a comparison is made of the first six completed wet holes bored in this test. It will be seen at once that the Kimber hammer

this 40.7 in. only 6 in. was bored with the starter, 8.8 in. with the second, 10.5 in. with the third, and 15.35 in. with the 1½-in. finishing bit. In actual underground work the steel used would be somewhat bigger.

It will be seen that of the piston machines both the Chersén, 2¾-in. diameter and 6-in. stroke, and the Ingersoll Baby, 2½-in. diameter and 5-in. stroke, as well as the Flottman hammer drill show a higher average rate of boring speed per minute of actual drilling time than the Gordon drill and that the Kid drill, 2-in. diameter and 5-in. stroke, drilled about as fast in spite of the fact that broken steel spoiled its performance. The Little Wonder and the Holman 2-in. drills also were not far behind. The result of this competition, however, tends to bear out the American experience that I quoted in another article of a different type of hammer drill compared with a 2½-in. piston machine. Where the Gordon or other water-feed type of hammer drill shows superiority is, first, in the ease and rapidity of erection, and second, in its power to bore with equal speed in any direction.

TABLE I. RESULTS OF SOUTH AFRICAN MINES STOPE-DRILL CONTEST.

Name of Machine.	Type.	Size of Starter Bit, Inches.	Cubic Inches Rock Per 1 In. Drilled.	Rate of Boring, Inches Per Minute.	Size of Finishing Bit, Inches.	Cubic Inches Rock Per 1 In. Drilled.	Rate of Boring, Inches Per Minute.	Percentage Decrease of Rock Cut in Smaller Hole Compared With Larger.	Increase Per Cent. of Smaller Hole Compared With Larger.
Kimber.	Hammer	1½	2.76	1.13	1½	1.22	2.01	55.8	77.8
Little Wonder.	2-in. piston	1½	2.40	0.80	1½	0.99	1.30	58.7	62.5
Gordon.	Hammer	1½	1.76	1.61	1½	0.99	1.29	43.7	16.7
